2021 marks the start of my 35th year as a family doctor and an opportunity to reflect on the tremendous changes that have occurred over my career. Clinicians of all specialties are besieged to provide high value care, while still struggling to incorporate electronic health records into their practices in a meaningful manner. Patient expectations are at an all-time high, with Internet-acquired ideas and suggestions. Meanwhile, quality parameters for which we often have little control or that do not really reflect improvements in care, drive many of our actions.

Provider wellness is front page news, with a call for increased ‘resiliency’ and relaxation exercises rather than fixing the system! Despite the frustrations of the health care system in our world, I remain happy as a practicing family doc. What has not changed over the years is the need for a patient relationship that is built on trust. As Francis W. Peabody wrote in 1927, “One of the essential qualities of the clinician is interest in humanity, for the secret of the care of the patient is in caring for the patient.” That has not changed!

This edition is dedicated to the primary care clinicians who every day devote themselves to caring for their patients. You are a remarkable group. If the pressures and changes in medicine are getting you down, “run to the fire;” consider taking a student or two every year in your practice to precept, exposing them to the joys of caring for your patients.

Mary Angelina Baldor, my mother, who at the age of 95, remains a positive influence in my life! Each morning she wakes greeting another day with a smile. Without realizing it, she has taught me the power of positive thinking, the benefits of working hard, and taking time to play. My mom was a role model of nurturing and caring for those around her. I have also been blessed with healthy and happy children (Anthony, Jocelyn, Daniel, John, Angelina and Ella). They need to know each is my ‘favorite’! My life has been further enriched with 3 precious grandchildren (Layla, Lennon and Ponder); they are a delight.

My wife Carol has been a source of support and without her understanding and patience with my workaholic nature, none of my efforts would be successful. From her I have learned the value of wonder and acceptance of those less fortunate. Her insights about the world around me and the need to stop and reflect are just part of why I am grateful for her being in my life. Her love and devotion sustain me, making every day a joy!

ROBERT A. BLDOR, MD
PREFACE

“The world is changed by your example, not by your opinion.”

Paulo Coelho

What we do, in the exam room, on the phone, and in our daily lives; these actions define how we help change our patients’ future.

Too often, we hear colleagues and friends giving us their opinion on how the world should be. But more important is how they treat others. The advent of social media has (unconsciously) taught us that our opinions, even those improper to say in private, are OK to voice digitally. These actions, and their associated words, have brought us into an age of divisiveness.

It is an individual’s behavior, their actions, that speak their true selves. When we engage our patients, we are asked to be their nonjudgmental “safe place.” Your objectivity is the very foundation of the relationship. Being open to your patients’ lives, even if their world differs from yours, is the first act of changing the world to one of tolerance.

“Integrity is doing the right thing, even when no one is watching.”

C.S. Lewis

Welcome to the 2021 edition of The 5-Minute Clinical Consult. Your clinical practice is full of challenges and unanswered questions. Your use of this amazing tool will provide you with the answers needed to help your patients live to their fullest.

The 5-Minute Clinical Consult is here to assist in fulfilling our role as health care providers. In each patient interaction, in addition to bringing your clinical expertise, remember how your patients view you, as their advocate, someone who prioritizes their well-being unlike anyone else.

Our editorial team has collaborated with hundreds of authors so that you may deliver your patients the best care. Each topic provides you with quick answers you can trust, where and when you need them most, either in print or online at www.5MinuteConsult.com.

This highly organized content online provides you with the following:
- Differential diagnosis support from our expanded collection of algorithms
- Current evidence-based designations highlighted in each topic
- 540+ commonly encountered diseases in print, with an additional 1,500 online topics, including content from The 5-Minute Pediatric Consult and The 5-Minute Sports Medicine Consult
- FREE point-of-care CME and CE: 1/2 hour credit for every digital search
- Thousands of images to help support visual diagnosis of all conditions
- Video library of procedures, treatment, and physical therapy
- A to Z drug database from Facts & Comparisons
Laboratory test interpretation from Wallach’s Interpretation of Diagnostic Tests
More than 3,000 patient handouts in English and Spanish
ICD-10 codes and DSM-5 criteria; additionally, SNOMED codes are available online.

Our website, www.5MinuteConsult.com, delivers quick answers to your questions. It is an ideal resource for patient care. Integrating The 5-Minute Clinical Consult content into your workflow is easy and fast, and our patient education handouts can assist in helping you meet meaningful use compliance.

The site promises an easy-to-use interface, allowing smooth maneuverability between topics, algorithms, images, videos, and patient education materials as well as more than 1,500 online-only topics. Register today for a free 10-day trial at www.5MinuteConsult.com!

Evidence-based health care is the integration of the best medical information with the values of the patient and your skill as a clinician. We have updated our evidence-based medicine (EBM) content so you can focus on how to best apply it in your practice.

The algorithm section includes both diagnostic and treatment algorithms. This easy-to-use graphic method helps you evaluate an abnormal finding and prioritize treatment. They are also excellent teaching tools, so share them with the learners in your office.

This book and website are a source to solve problems and to help evaluate, diagnose, and treat patients’ concerns. Use your knowledge, expressed through your words and actions, to address their anxiety.

The 5-Minute Clinical Consult editorial team values your observations, so please share your thoughts, suggestions, and constructive criticism through our website: www.5MinuteConsult.com.

FRANK J. DOMINO, MD
Remember when we used to treat every otitis media with antibiotics? These recommendations came about because we applied logical reasoning to observational studies. If bacteria cause an acute otitis media, then antibiotics should help it resolve sooner, with less morbidity. Yet, when rigorously studied (via a systematic review), we found little benefit to this intervention.

The underlying premise of EBM is the evaluation of medical interventions and the literature that supports those interventions, in a systematic fashion. EBM hopes to encourage treatments proven to be effective and safe. And when insufficient data exist, it hopes to inform you on how to safely proceed.

EBM uses end points of real patient outcomes, morbidity, mortality, and risk. It focuses less on intermediate outcomes (bone density) and more on patient conditions (hip fractures).

Implementing EBM requires three components: the best medical evidence, the skill and experience of the provider, and the values of the patients. Should this patient be screened for prostate cancer? It depends on what is known about the test, on what you know of its benefits and harms, your ability to communicate that information, and that patient’s informed choice.

This book hopes to address the first EBM component, providing you access to the best information in a quick format. Although not every test or treatment has this level of detail, many of the included interventions here use systematic review literature support.

The language of medical statistics is useful in interpreting the concepts of EBM. Below is a list of these terms, with examples to help take the confusion and mystery out of their use.

**Prevalence:** proportion of people in a population who have a disease (in the United States, 0.3% [3 in 1,000] people >50 years have colon cancer)

**Incidence:** how many new cases of a disease occur in a population during an interval of time; for example, “The estimated incidence of colon cancer in the United States is 104,000 in 2005.”

**Sensitivity:** percentage of people with disease who test positive; for mammography, the sensitivity is 71–96%.

**Specificity:** percentage of people without disease who test negative; for mammography, the specificity is 94–97%.

Suppose you saw ML, a 53-year-old woman, for a health maintenance visit, ordered a screening mammogram, and the report demonstrates an irregular area of microcalcifications. She is waiting in your office to receive her test results, what can you tell her?

Sensitivity and specificity refer to characteristics of people who are known to have disease (sensitivity) or those who are known not to have disease (specificity). But, what you have is an
abnormal test result. To better explain this result to ML, you need the positive predictive value.

**Positive predictive value (PPV):** percentage of positive test results that are truly positive; the PPV for a woman aged 50 to 59 years is approximately 22%. That is to say that only 22% of abnormal screening mammograms in this group truly identified cancer. The other 78% are false positives.

You can tell ML only 1 out of 5 abnormal mammograms correctly identifies cancer; the four are false positives, but the only way to know which mammogram is correct is to do further testing.

**The corollary of the PPV is the negative predictive value (NPV),** which is the percentage of negative test results that are truly negative.

The PPV and NPV tests are population dependent, whereas the sensitivity and specificity are characteristics of the test and have little to do with the patient in front of you. So when you receive an abnormal lab result, especially a screening test such as mammography, understand their limits based on their PPV and NPV.

**Treatment information is a little different.** In discerning the statistics of randomized controlled trials of interventions, first consider an example. The Scandinavian Simvastatin Survival Study (4S) (*Lancet*. 1994;344[8934]:1383–1389) found using simvastatin in patients at high risk for heart disease for 5 years resulted in death for 8% of simvastatin patients versus 12% of those on placebo; this results in a relative risk of 0.70, a relative risk reduction of 33%, and a number needed to treat of 25.

There are two ways of considering the benefits of an intervention with respect to a given outcome. The absolute risk reduction is the difference in the percentage of people with the condition before and after the intervention. Thus, if the incidence of myocardial infarction (MI) was 12% for the placebo group and 8% for the simvastatin group, the absolute risk reduction is 4% (12% − 8% = 4%).

The relative risk reduction reflects the improvement in the outcome as a percentage of the original rate and is commonly used to exaggerate the benefit of an intervention. Thus, if the risk of MI were reduced by simvastatin from 12% to 8%, then the relative risk reduction would be 33% (4% / 12% = 33%); 33% sounds better than 4%, but the 4% is the absolute risk reduction and reflects the true outcome.

Absolute risk reduction is usually a better measure of clinical significance of an intervention. For instance, in one study, the treatment of mild hypertension has been shown to have relative risk reduction of 40% over 5 years (40% fewer strokes in the treated group). However, the absolute risk reduction was only 1.3%. Because mild hypertension is not strongly associated with strokes, aggressive treatment of mild hypertension yields only a small clinical benefit. Don’t confuse relative risk reduction with relative risk.

**Absolute (or attributable) risk (AR):** the percentage of people in the placebo or intervention group who reach an end point; in the simvastatin study, the absolute risk of death was 8%. 
**Relative risk (RR):** the risk of disease of those treated or exposed to some intervention (i.e., simvastatin) divided by those in the placebo group or who were untreated
- If RR is <1.0, it reduces risk—the smaller the number, the greater the risk reduction.
- If RR is >1.0, it increases risk—the greater the number, the greater the risk increase.

**Relative risk reduction (RRR):** the relative decrease in risk of an end point compared to the percentage of that end point in the placebo group
If you are still confused, just remember that the RRR is an overestimation of the actual effect.

**Number needed to treat (NNT):** This is the number of people who need to be treated by an intervention to prevent one adverse outcome. A “good” NNT can be a large number (>100) if risk of serious outcome is great. If the risk of an outcome is not that dangerous, then lower (<25) NNTs are preferred.
The NNT should be compared to a similar statistic, the number needed to harm (NNH). This is the number of people who have to be given treatment before one excess side effect or harm occurs. When the NNT is compared to the NNH, you and the patient can judge whether the benefit of the intervention is great enough to outweigh the risk of harm.

**EVIDENCED-BASED GRADING**
To help you interpret diagnostic and treatment recommendations within The 5-Minute Clinical Consult, we have graded the best information within the text and highlighted this content.

An “A” grade means the reference is from the highest quality resource, such as a systematic review. A systematic review is a summary of the medical literature on a given topic that uses strict, explicit methods to perform a thorough search of the literature and then provides a critical appraisal of individual studies, concluding in a recommendation. The most prestigious collection of systematic reviews is from the Cochrane Collaboration (www.cochrane.org).

A “B” grade means the data referenced comes from high-quality randomized controlled trials performed to minimize bias in their outcome. Bias is anything that interferes with the truth; in the medical literature, it is often unintentional, but it is much more common than we appreciate. In short, always assume some degree of bias exist in any research endeavor.

A “C” grade implies the reference used does not meet the A or B requirements; they are often treatments recommended by consensus groups (such as the American Cancer Society). In some cases, they may be the standards of care. But implicit in a group’s recommendation is the bias of the author or the group that supports the reference. For example, the American Urological Society’s recommendation around screening for prostate cancer may be motivated by their narrow scope and financial benefit. Compare this to the recommendations of the U.S. Preventive Services Task Force (www.ahrq.gov), which recommends against screening for prostate cancer.

**BIAS**
Bias is anything that interferes with the truth. There are many types of bias that should be considered by the publishers of medical information. Below describes a number of bias types that often affect our care without us knowing it is present.

**Publication bias** occurs when research is not published; this is often when a study finds
data that does not support an intervention. The motivation to publish information that “didn’t work” is low. It is estimated that up to 40% of all medical research never get published. When you read of an effective intervention, wonder if other studies did not show benefit and went unpublished.

**Comparator bias** occurs when research compares an intervention to not the standard of care. Knowing a new treatment is more effective than placebo for treating a condition is not helpful if you typically use a drug or procedure. Why not study comparing the new to the standard of care? Sometimes, the new treatment is no better than the current standard. And if a study was done to see if the new is better than the old and not published, you have an example of publication bias.

**Selection bias** involves choosing study populations that might be different than the average patient or just reporting a just subset of study participants from a study. Either will result in the data being skewed because it can only be applied to small subset of people.

**Attrition bias and the concept of intention to treat.** Attrition bias is when researchers do not fully acknowledge and address how a study deals with participants who do not adhere to the research protocol or drop out completely. Intention to treat analysis hopes to diminish attrition bias by statistically considering the nonadhering or dropped out patients as unsuccessfully benefiting from the intervention.

**Commercial (funder) bias** involves who paid for the research being done, and do they have a vested interest in the outcome. If the developer of a new drug does a large study, or a researcher has a personal financial interest in seeing a study succeed, they may consciously or unconsciously alter what is reported in a study. The data may be accurate, but until this is studied by less vested interests, some feel its outcome cannot be clinically applied.

Have you been annoyed how 1 week you learn of a randomized controlled trial that supports a treatment, to be followed the next week with a contradictory article? Statisticians have figured out how to resolve this using something called a systematic review.

**A systematic review** gathers all the literature on a topic, say using antibiotics to treat otitis media, and combines the data to determine if the sum of all the trials tells a different story than any single trial. The large number of participants in this type of research results in a much more statistically (and clinically) significant conclusion than any single paper. Want more? Check this out: [http://community.cochrane.org/about-us/evidence-based-health-care](http://community.cochrane.org/about-us/evidence-based-health-care).

**A meta-analysis** is a quantitative systematic review and demonstrates its outcomes in the form of a forest plot. The bottom line with interpretation of a forest plot is to look for the diamond on the bottom. If it is to LEFT of the vertical line, it means risk of an outcome was reduced by the intervention. If it is fully to the RIGHT, then risk of that outcome was increased. And if the diamond touches the vertical line, it means there was no statistical influence of the intervention on the outcome.

We hope this brief introduction to EBM has been informative, clear, and helpful. If any of the information above seems unclear, or if you have a question, please contact us via [www.5MinuteConsult.com](http://www.5MinuteConsult.com).
ACKNOWLEDGMENTS

This is the 29th edition of The 5-Minute Clinical Consult, a comprehensive point-of-care tool to assist in the care of patients. From beginning to end, one cannot find a more current and easy-to-use collection of clinically useful content.

Developing and maintaining a book and website of this magnitude requires an equally broad effort from its supporting team. I wish to thank the dedication and tireless efforts of many: director, medical practice, Rebecca Schmidt; content editing manager, Leanne Vandetty; and publisher, Lisa McAllister.

This 2021 edition is the direct result of the dedication and insights of our associate editors. I wish to thank Drs. Robert Baldor, Jeremy Golding, and Mark Stephens for their hard work and overwhelming commitment to The 5-Minute Clinical Consult. And welcome the amazing Dr. Kathleen Barry to our team of editors.

I wish to especially thank my wife, Sylvia, and my daughter, Molly, who have given greatly for this book.

The challenge of completing a book covering this broad spectrum of medicine requires insights and skills far beyond my own. Many thanks to my mentors Bob Baldor and Mark Quirk who have been an enormous support—always there to encourage, reassure, and impart wisdom.

Many in the academic and health care worlds are due thanks for support, insight, and friendship: Daniel Lasser, M. Diane McKee, Michele Pugnaire, Karen Rayla, Maryanne Adams, Jennifer Masoud, Phil Fournier, Erik Garcia, Jeff Stovall, Jim Comes, Leah Honor, J. Herb Stevenson, Michael Kidd, Zainab Nawab, Sanjiv and Amita Chopra, Vasilios (Bill) Chrisostomidis, James (Jay) Broadhurst, Danuta Antkowiak†, Atreyi Chakrabarti, Joseph Frappier, Kate Peasha, the staff of Shrewsbury Family Medicine, Deb Huchowski, Joyce Paquette, Kate Peasha, Priscila Velez, Fanny Rodriguez, Meghan Plaza, and Angie Dell’Ovo, Brittany McLean, Mark Powicki, Steve Messineo, Rick Watson and Sara Floros, Frits Pennings, and the faculty and amazing students of the University of Massachusetts Medical School.

Medicine is a challenge I have fortunately not had to meet alone. Thanks to my parents, Frank and Angela (Jean); my brother, John, and his family, Marylou, Cate, and Jane; Frank, Mary Anne, Diane, and David Christian; the Diana and Hymie Lipschitz family; and the Bob and Ruth Pabreza family; they are responsible for who I am and my success in life.

I am blessed with the best of friends; without them, I would not be a physician. Thanks to Bob Bacic; Ron Jautz; Richard Onorato; John Horcher; Auguste Turnier; Bob Smith; Paul Saivetz; Bob and Nancy Gallinaro; Drew and Jill Grimes; Louay Toma; Laurie, Alan, Daniel, Jenny, and Matt Bugos; Alan Ehrlich; Andy Jennings; Bill Demianiku; Mark Steenbergen; John and Kathleen Polanowicz; Phil and Carol Pettine; Mark and Linda Shelton; Steve Bennett; Vicki Triolo; Bob and Laurie Jenal; and Michael Bernatchez.

Co-Director Breast and Gynecologic Pathology Fellowship
Kimberly S. Tustison, MD
Assistant Clinical Professor
Department of Women’s Health
University of California Riverside School of Medicine
Riverside, California

Ashley Twyman, MD
Resident
University of Louisville
Louisville, Kentucky

Katherine S. Upchurch, MD, MACR
Professor of Medicine
University of Massachusetts Medical School
Division of Rheumatology
University of Massachusetts Memorial Medical Center
Worcester, Massachusetts

Sara Usman, MBBS
Dow University of Health Sciences
Karachi, Pakistan

Onameyore Utuama, MD, MPH
Hospitalist
Physicians of Central Florida
Mt. Dora, Florida

Sonal Vaid, MD, BME
Internal Medicine Resident Physician
Department of Internal Medicine
Indianapolis, Indiana

Santiago O. Valdes, MD, FAAP
Associate Professor
The Lillie Frank Abercrombie Section of Pediatric Cardiology
Texas Children’s Hospital
Baylor College of Medicine
Houston, Texas
Carrie Valenta, MD, FACP, FHM  
Assistant Professor of Internal Medicine  
Division Chief of Academic Hospital Medicine  
CHI Health Creighton University Medical Center  
Creighton University School of Medicine  
Omaha, Nebraska

Virginia J. Van Duyne, MD  
Assistant Professor and Associate Residency Director  
Department of Family Medicine and Community Health  
University of Massachusetts Medical School  
Worcester, Massachusetts

Pratibha Sonam Vashista, DO  
Resident Physician  
Department of Family Medicine  
Novant Health Family Medicine Residency Program  
Cornelius, North Carolina

Kathleen M. Vazzana, DO, MSc  
Pediatric Rheumatology Fellow  
Children’s National Medical Center  
Washington, District of Columbia

Nandhini Veeraraghavan, MD, CAQSM, FAAFP  
Associate Program Director  
Family Medicine Residency  
St. Luke’s Sacred Heart Campus  
Allentown, Pennsylvania

Pradeepa P. Vimalachandran, MD, MPH  
Rural Health Family Medicine Physician  
Oakland Mercy Medical Hospital  
Oakland, Nebraska

Alicia H. Vinyard, DO  
Assistant Professor of Surgery  
Associate Surgery Clerkship Director  
Department of Surgical Oncology  
Augusta University Medical Center  
Augusta, Georgia

Kirsten Vitrikas, MD†  
Program Director
David Grant Medical Center
Family Medicine Residency
Travis Air Force Base, California

Elena Voronejskaia, MD
Resident
Department of Family Medicine
Prisma Health
Greenville, South Carolina

Yongkasem Vorasettakarnkij, MD, MSc†
Faculty of Medicine
Department of Medicine
Chulalongkorn University
Cardiac Center
King Chulalongkorn Memorial Hospital
Thai Red Cross Society
Bangkok, Thailand

Joseph R. Wagner, MD
Urologic Oncology and Minimally Invasive Surgery
Hartford Healthcare Medical Group
Director of Robotic Surgery
Hartford Hospital
Hartford, Connecticut

Thomas A. Waller, MD
Assistant Professor of Family Medicine
Residency Director
Department of Family Medicine
Mayo Clinic Florida
Jacksonville, Florida

Anne Walsh, ANP-BC
Northwell Health Solutions House Calls Program
New Hyde Park, New York
Adjunct Clinical Faculty
Hofstra University School of Graduate Nursing and PA Studies
Hempstead, New York

Judy Wang, MD
Resident
Family Medicine and Community Health
Family Medicine Worcester
Family Health Center of Worcester
UMass Medical School
Worcester, Massachusetts

Ming-Jin Wang, DO
Hematology Oncology Fellow
Department of Hematology Oncology
University of Massachusetts
Worcester, Massachusetts

Samuel C. Wang, MD, FAAFP
Associate Program Director
Memorial Family Medicine Residency Program
Sugar Land, Texas

Sicong Wang, MD†
Department of Family Medicine
Madigan Army Medical Center
Joint Base Lewis—McChord, Washington

Waiz Wasey, MD
Fellow
Department of Sleep Medicine
Mayo Clinic Florida
Jacksonville, Florida

Joshua Wathen, MD
Resident Physician
Department of Pediatrics
University of California Irvine – Children’s Hospital of Orange County
Orange, California

Lynn Weaver, MD
Resident
Department of Family and Community Medicine
Penn State College of Medicine
Hershey, Pennsylvania

Kaci Webb, MD
Family Medicine Resident Physician
Department of Population Health
The University of Texas at Austin Dell Medical School
Austin, Texas

Grant Wei, MD
Associate Professor
Program Director
Department of Emergency Medicine
Rutgers Robert Wood Johnson Medical School
New Brunswick, New Jersey

Kendra Weissberger, BSN, FNP-BC
Family Nurse Practitioner
New Hyde Park, New York

Maggie C. Wertz, MD†
Operational Physician
Fort Gordon, Georgia

Rebecca Wetzel, DO†
CPT, MC, USA
Internal Medicine
Walter Reed National Military Medical Center
Bethesda, Maryland

Amanda E. White, DO, MBA
Novant Health Family Medicine Residency Clinic-Cornelius
Cornelius, North Carolina

Cassandra Q. White, MD, FACS
Assistant Professor and Program Director
Surgical Critical Care Fellowship
Department of Surgery
Medical College of Georgia at Augusta University
Augusta, Georgia

Christopher White, MD, JD, MHA
Associate Professor and Research Division Director
Department of Family and Community Medicine
University of Cincinnati College of Medicine
Cincinnati, Ohio

Todd A. Wical, DO†
Family Medicine Resident
Department of Primary Care
Martin Army Community Hospital
Fort Benning, Georgia

Marcy Wiemers, MD
Assistant Professor/Clinical Associate Program Director
University of Texas Health Science Center San Antonio Family and Community Medicine Residency
San Antonio, Texas

Susanne Wild, MD
Associate Program Director for Academic Affairs
Banner University Medical Center Phoenix Family Medicine Residency
Clinical Assistant Professor
Department of Family and Community Medicine
University of Arizona College of Medicine
Phoenix, Arizona

Faren H. Williams, MD, MS†
Chief and Clinical Professor, Physical Medicine & Rehabilitation
Department of Orthopedics and Physical Rehabilitation
University of Massachusetts Medical School
Worcester, Massachusetts

Katherine Williams, MD
Resident, Family Medicine
Summa Health
Akron, Ohio

Norton A. Winer, MD
Assistant Clinical Professor of Neurology
Case Western Reserve University School of Medicine
Division Chief Neurology
UH Richmond Medical Center
Cleveland, Ohio

Robyn Wing, MD, MPH
Assistant Professor of Emergency Medicine & Pediatrics
Departments of Emergency Medicine & Pediatrics
Alpert Medical School of Brown University
Providence, Rhode Island

Fawn J. Winkelman, DO
Elite Medicine and Aesthetic Institute
Clinical Assistant Professor
Department of Osteopathic Family Medicine
Nova Southeastern University of Osteopathic Medicine
Boca Raton, Florida
Jay Winner, MD, FAAFP  
Family Physician and Founder/Teacher Stress Reduction Classes  
Sansum Clinic  
Santa Barbara, California  
Clinical Assistant Professor of Family Medicine  
University of Southern California School of Medicine  
Los Angeles, California

Christopher M. Wise, MD  
Division of Rheumatology, Allergy, and Immunology  
Virginia Commonwealth University Health System  
Richmond, Virginia

Amy L. Wiser, MD  
Assistant Professor  
Department of Family Medicine  
Oregon Health & Science University  
Portland, Oregon

Anita Wong, MD  
Department of Family Medicine  
UCLA Medical Center, Santa Monica  
Santa Monica, California

William W. Wong, DO†  
Assistant Professor of Medicine  
University of Massachusetts Medical School  
Worcester, Massachusetts

J. Andrew Woods, PharmD, BCPS  
Associate Professor of Pharmacy  
Wingate University School of Pharmacy  
Wingate, North Carolina

Taylor Wright, MD  
Assistant Professor of Family Medicine  
University of Tennessee, Knoxville  
Knoxville, Tennessee

Frances Y. Wu, MD, FAAFP  
Assistant Professor of Family Medicine  
Assistant Director  
Robert Wood Johnson Somerset Family Medicine Residency  
Robert Wood Johnson Medical School Rutgers University
Somerville, New Jersey

Kai-Soon “David” Yang, MD
Family Practice
Methodist Charlton Medical Center
Dallas, Texas

Wail Yar, MD, MPH
Resident Physician
Department of Family Medicine
Case Western Reserve University/University Hospitals
Cleveland, Ohio

Dinesh Yogaratnam, PharmD
Assistant Professor
School of Pharmacy Worcester/Manchester
Massachusetts College of Pharmacy and Health Sciences University
Worcester, Massachusetts

James R. Yon, MD
Department of Trauma and Acute Care Surgery
Swedish Medical Center
Englewood, Colorado

Kyung In Yoon, MD
Department of Emergency Medicine
Robert Wood Johnson University Hospital
New Brunswick, New Jersey

Jocelyn C. Young, DO, MS
Faculty Physician
Department of Family Medicine
United Health Services Hospitals
Johnson City, New York

David H. Yun, MD†
Family Physician
Okubo Family Health Clinic
Joint Base Lewis—McCord, Washington

Edlira Yzeiraj, DO, MS
Internal Medicine
Cleveland Clinic
Cleveland, Ohio
Christopher A. Zagar, MD, FAAFP  
Associate Program Director  
Family Medicine Residency Program  
Novant Health  
Cornelius, North Carolina

Rochelle Zak, MD  
Associate Professor  
Department of Medicine/Sleep Disorders Center  
University of California at San Francisco  
San Francisco, California

Youhua Zhang, MD, PhD  
Associate Professor  
Department of Biomedical Sciences  
New York Institute of Technology College of Osteopathic Medicine  
Old Westbury, New York

Anna K. Zheng, MD  
Assistant Professor, Appointment Pending  
University of Massachusetts Memorial Medical Center  
Department of Family Medicine and Community Health  
Edward M. Kennedy Community Health Center  
Worcester, Massachusetts

Erika Zimmons, DO, MS  
Assistant Professor  
Department of Family Medicine and Community Health  
Division of Geriatric Medicine  
University of Massachusetts Medical School  
Worcester, Massachusetts

Gennine M. Zinner, RNCS, ANP  
Clinical Professor  
Massachusetts General Hospital Institute of Health Professions  
Nurse Practitioner  
Boston Health Care for the Homeless Program  
Boston, Massachusetts

Patrick M. Zito, DO  
Faculty, School of Nursing  
Walden University;  
Minneapolis, Minnesota
Susan L. Zweizig, MD
Professor and Director
Division of Gynecologic Oncology
Department of Obstetrics and Gynecology
University of Massachusetts Medical School
Worcester, Massachusetts

Diagnosis and Treatment:  
An Algorithmic Approach

This section contains flowcharts (or algorithms) to help the reader in the diagnosis of clinical signs and symptoms and treatment of a variety of clinical problems. They are organized by the presenting sign, symptom, or diagnosis.

These algorithms were designed to be used as a quick reference and adjunct to the reader’s clinical knowledge and impression. They are not an exhaustive review of the management of a problem, nor are they meant to be a complete list of diseases.
ABDOMINAL PAIN, CHRONIC

Common causes: IBS, functional dyspepsia, dominant viscera, hx of inceasugage, celiac, IBD, endometriosis, anxiety, child abuse/neglect, abdominal pain, IBD, PUD, GERD

Screen for intimate partner violence, abuse/neglect

Red Flag Symptoms
- Anorexia/loss of appetite
- Weight loss/growth restriction
- Fever
- Onset < age 50

Labs: CBC, ESR/CRP, LFTs, TSH, omlyase, lipase, anti-TG, PPD, stool guaiac, Giardia, HIV, C diff
Imaging: Upper/lower endoscopy, CT scan

<10 Years old

Lower abdomen of female?

Lead Risk?
- Diet associated (gluten, lactose)?
- Hypoallergenic diet failure?

Home IV Criteria:
- Likely IBS
- met and negative for anti-TG?

Establish safety plan, 1-800-799-7202
- Refer for counseling.

Neg. Celiac's Sign

DDx: Psychosocial, Functional Dyspepsia, GERD, Medication related

"Red Flag" Labs and Imaging as needed
- GI Referral as needed

Francis G. Gause, MD and Christopher C. Taylor, MD
ABDOMINAL PAIN, LOWER

Maegen V. Dupper, MD and Kenneth A. Ballou, MD, FAAFP
ABDOMINAL PAIN, UPPER

Common causes: GERD, functional dyspepsia, PUD, gastritis, pancreatitis, biliary dyskinesia, angina, esophageal/gastric cancer, medications, IBS

Acute (<12 hours) severe pain + hypotension or tachycardia?

Stabilize patient. US, CT chest/abdomen.

Acute dissection, AAA, severe acute pancreatitis, perforated viscus, peritonitis, mesenteric ischemia

Suspicion of cardiac disease?

QI alarm symptoms:
- Bleeding
- Tachycardia
- Hypotension
- Hypertension
- Hematemesis
- Melaena
- Fatigue, SOB
- Drop in hematocrit

Neoplasm: weight loss, age >60 years, family hx of gastrectomies, malignancy, anemia, dysphagia, crampy colicky

Angina, MI pericarditis

No alarm symptoms

Endoscopy

PUD, esophageal/gastric carcinoma

Fever, tenderness

LUQ pain

RUQ pain

Pain radiating to back, hx of alcohol abuse, gallstones, recent ERCP, hypertrophic pyloric stenosis, hypercalcemia, pancreatitis

Indigestion, bloating

Heartburn, acidic taste in mouth, worse at night

Symptoms that do not resolve with PPI

Chest pain or cough

D-dimer, CXR

Splenic aneurysm, infant, diaphragmatic hernia

Cholangitis

Acute, acute hepatic, Budd-Chiari syndrome

Ascending cholangitis, biliary colic

Pancreatitis

IBS, PUD, gastroparesis, gout, GERD

Functional dyspepsia, IBS

Pneumonia, pulmonary embolism

Sumedha Singh, MD and Marie L. Borum, MD, EdD, MPH, MACP, FACG, AGAF

Marissa T. Christian, PharmD, Ryan B. Feeney, PharmD, BCPS, BCGP, and
Dean A. Christian, MD

ACIDOSIS

Consider acidosis in setting of the following:
- Altered mental status
- Abnormal breathing
- Known drug overdose
- Severe infection, trauma, inflammation
- Respiratory distress

Note: Renal response to respiratory acidosis may occur over days; may not see low HCO₃⁻ immediately

ABG
- pH < 7.35
- CO₂ > 40, or
- HCO₃⁻ < 18

PCO₂ > 457

No

Metabolic

Renal injury: acute or chronic kidney injury
Check Cr and GFR.

Toxins: alcohols, narcotics, and benzodiazepines, ASA

Respiratory

Yes

Sorum anion gap normal?
Na+ - (Cl⁻ + HCO₃⁻) = 3-11 mEq/L

No

Lactic acidosis: sepsis, shock, malignancy, medications, metabolic disorders
Check lactate levels.

Yes

Normal anion gap (hyperchloremic) metabolic acidosis

Ketosis: DKA, alcoholic, ketoacidosis
Check urine and plasma ketones.

Cardiac: acute cardiogenic pulmonary edema, CHF exacerbation

Central hyperventilation: drugs, cardiac arrest, sleep apnea, obesity, hyperventilation

Pulmonary: COPD, asthma, pneumonia, ARDS, pneumothorax—hemorrhage, restrictive lung disease

Renal tubular acidosis (RTA):
- RTA type 1: distal failure of acid secretion; hypokalemia, high urine pH (pH > 5.5)
- RTA type 2: proximal failure of bicarbonate reabsorption; low urine pH (pH < 5.5)
- RTA type 4: decreased proximal ammonia production due to hyperparathyroidism, hyperkalemia

GI losses of HCO₃⁻: diarrhea, fistula
OR
Hyperalimentation: parental nutrition, overzealous

Frank J. Domino, MD
Emily Brown, MD and Eric J. Rosenthal, DO
ALCOHOL WITHDRAWAL, TREATMENT

Umer Farooq, MD and Stephen Paravati, MD
ALKALINE PHOSPHATASE ELEVATION

Reem Hadi, MD and Fozia Akhtar Ali, MD

AMENORRHEA, SECONDARY

Absence of menses >3 months in woman with regular periods
OR
Absence of menses >6 months in a woman with irregular periods

Common causes: pregnancy, ectopic pregnancy, anorexia/nervosa, infection, PCOS, ovarian failure (menopause), pituitary adenoma, hypothyroidism

Urine or Serum HCG

Intrauterine pregnancy, ectopic pregnancy

Vaginal/bimanual exam
• FSH, LH, TSH, prolactin, BMP

Stress
• Weight loss
• Extreme exercise

Anorexia nervosa
• BMI <15
• Deepening of voice, LH/FSH ratio >2

Obstructive sleep apnea
• Sleep difficulty
• Decreased Iodine

Check labs: DHEA-S, testosterone (increased), transvaginal ultrasound (US)

PCOS

Menopause

Pituitary adenoma

Renal disease

FSH

Elevated TSH

Hyperthyroidism

Galsactorrhea

↓ Serum prolactin

Pituitary MRI

↓ Creatinine

Medications:
• Oral contraceptives
• Menopausal
• Antidepressants

Normal labs

GYN exam, transvaginal US

Obtain the following:
• Correct serum testosterone
• Cushing disease
• Androgen tumor

Konstantinos E. Deligiannidis, MD, MPH, FAAFP and Kendra Weissberger, BSN, FNP-BC

Asthma Exacerbation, Pediatric Acute

Initial Evaluation: Brief history of present illness, physical exam
- Asthma history: emergency department visits, hospital and ICU admissions, home medications, frequency of oral steroid use, history of hospitalization, rapid progressive episodes, food allergies
- Physical exam: auscultation, use of accessory muscles, ability to speak, heart rate, oxygen saturation, PEF, or FEV1

Severity

PEF, or PEF <40%

Mild exacerbation: Inhaled β2-agonist (nebulized or MDI) with metered dose inhaler (MDI) or patient-controlled nebulizer (PCN) if not immediate response or history of recent course of corticosteroids. Check initial oxygen saturation level; no need for continuous pulse-oximetry monitoring. Consider nebulized albuterol in place of albuterol if MDI ADR.

Moderate exacerbation: Inhaled β2-agonist in combination with inhaled corticosteroids (PMD) or systemic corticosteroids (POC). Supplemental O2 to achieve SaO2 >90%.

Severe exacerbation: Inhaled β2-agonist in combination with ipratropium nebulized (100–200 µg/min × 3 doses or continuous for 1 hour), systemic corticosteroids (POC), supplemental O2 to achieve SaO2 >90%.

Consider methylxanthine if imminent respiratory failure.

Consider nebulized albuterol in place of albuterol if MDI ADR.

Discharge Criteria met?
- Decreased or absent wheezing and retractions
- Sustained SaO2 >90% at least 60 minutes after last albuterol dose

Yes

No

PEF, or PEF <40%

Severe exacerbation: Severe symptoms at rest; accessory muscle use; no improvement after initial treatment, nebulized β2-agonist in combination with ipratropium 150–300 µg/min or continuous; consider magnesium sulfate IV; next, consider intravenous infusion if no response; consider heliox; consider endotracheal intubation for respiratory failure; make admission decision in 24 hours.

Discharge Criteria met?
- Decreased or absent wheezing and retractions
- Sustained SaO2 >90% at least 60 minutes after last albuterol dose

Yes

No

Aimee Kobjack, MD and Henry Del Rosario, MD
### Management of Chronic Asthma

**Classification of Asthma Severity in Youth 12 Years of Age and Adults**

<table>
<thead>
<tr>
<th>Components of Severity</th>
<th>Intermittent</th>
<th>Mild Persistent</th>
<th>Moderate Persistent</th>
<th>Severe Persistent</th>

**Lung function**

- Normal FEV1, between calculations
- FEV1 > 80% predicted
- FEV1/FVC normal
- FEV1 > 60% but < 80% predicted
- FEV1/FVC reduced ≥ 5%
- FEV1 < 60% predicted
- FEV1/FVC reduced ≥ 10%

**Asthma exacerbations requiring oral steroids**

<table>
<thead>
<tr>
<th>Year</th>
<th>0–2/year</th>
<th>&gt;2/year</th>
</tr>
</thead>
</table>

**Recommended Step for Initiating Treatment**

**Step 1**
- Preferred: Short-acting β2-agonist as needed

**Step 2**
- Preferred: Low-dose ICS
- Alternative: Leukotriene modifier, nedocromil, or theophylline

**Step 3**
- Preferred: Low-dose ICS + LABA or medium-dose ICS
- Alternative: Low-dose ICS + leukotriene modifier, theophylline, or altheolin

**Step 4**
- Preferred: Medium-dose ICS + LABA
- Alternative: Medium-dose ICS + levalbuterol or theophylline

**Step 5**
- Preferred: High-dose ICS + LABA and consider omalizumab for patients with allergies

**Step 6**
- Preferred: High-dose ICS + LABA + oral corticosteroids and consider omalizumab for patients with allergies

At each step, discuss patient education, environmental control, and management of comorbidities.

---

Kevin T. Abraham, MD and Claudeleedy Pierre, MD

ASTHMA, MAINTENANCE

Assessing control
Reevaluate patient in 2–6 weeks and adjust therapy based on components of control.

AZOTEMIA AND UREMIA

Azotemia is the elevation of blood urea nitrogen (BUN). It can be divided into prerenal, intrinsic renal, and postrenal azotemia based on the cause. This is important because treatments differ. Uremia is essentially symptomatic azotemia and is mostly due to the accumulation of BUN and other toxins or waste products normally filtered by the kidneys. Untreated uremia may progress to aurescens, coma, and death.

History and physical suggestive of etiology? Risk factors include older age, sepsis, shock due to any etiology, liver failure, use of IV contrast agents, and diabetes mellitus.

BUN/Cr ratio >2?

Yes

Prenal azotemia

~70% of AKI

Poor perfusion due to:
- Shock (septic, cardiogenic, or hypovolemic)
- Sepsis
- Congestive heart failure
- Dehydration
- Cinerosis/liver failure
- Medications:
  - NSAIDs
  - AIBs
  - ACE inhibitors
  - Captopril
  - Loop diuretics

No

Chronic renal disease:
- Diabetes mellitus
- Hypertension
- Glomerulonephritis
- Sarcoidosis
- Lupus

Urinary retention, palpable bladder and/or positive bladder ultrasound?

Consider renal ultrasound and UA or cath.

Obstruction?

Yes

Postrenal azotemia

Obstructive uropathy

BPH
- Benign prostatic hypertrophy
- Prostate, or bladder
- Neurogenic bladder

No

Renal azotemia

Medications:
- Aminoglycosides
- Sulfonamides
- IV contrast
- Lithium
- NSAIDs
- Penicillins
- Cephalosporines
- Acyclovir
- Interferon
- Phenylethylamine
- Phenol
- PPIs

Acute tubular necrosis
- Renal artery stenosis
- Collagen vascular disease
- Rhabdomyolysis
- Acute glomerulonephritis (e.g., postinfectious [Streptococcus], Goodpasture syndrome, or Wegener granulomatosis)

Steven A. House, MD, FAAFP, FAAHPM
Navpreet K. Singh, MD and Inderjit Singh, MD

CERVICAL HYPEREXTENSION INJURY

Sufficient mechanism of injury
Most common: NRPA, acceleration-deceleration, sports, falls (>2 feet),
and/or trauma above the clavicle (e.g., frontal head or neck)

If necessary, intubate using manual in-line stabilization
proceeding to secondary survey/mobilization.

Unstable

EMS primary survey

Stable

EMS primary survey

On-scene (BEMS)

Restrict activity until follow-up with physician.

NEXUS low-risk criteria
No posterior cervical tenderness
No abnormal level of alertness
No evidence of intoxication
No past/diagnosing injuries
No abnormal neurologic symptoms
Unconscious, numbness, weakness, paresthesia, or neck/point tenderness

Meet all five criteria:

No

Neurogenic shock
Admission IV fluids, emergent surgical decompression with post imaging.

IV fluids, blood transfusion, and pressure search for hemorrhagic source,
Intubate with ML if necessary.

Hemodynamically unstable

ARCOAs

Hemodynamically stable

Physician secondary survey

Imaging for clinically significant spinal injury

Rigid collar, scene brief

Mandatory C-spine and transport to medical facility

No helmet/pad

Hockey/football helmet and pads

Leave helmet/pads in place.

Remove fascial

No

Yes

Goal MAP
90 mm Hg

Physician primary survey

On-scene assessment/ exclusion (ASEX)
Assessment of mechanism—high risk?
Neurologic exam—impairment, sensory, or reflex? Pneumoperitoneum?
Need ROM - required?

Bi to all

Yes

Intubate C-spine and transport to medical facility

No
Bobby Peters, MD, FAAEM
CHEST PAIN/ACUTE CORONARY SYNDROME

Jeremy Golding, MD, FAAFP

CHILD ABUSE

What should you consider abuse?

---

**Physical abuse**
- When a child makes a disclosure.
- When there is no history to explain an injury.
- When the history is not consistent with the injury seen.
- When key parts of the history change.
- Any bruises or nonpitting edema that raise medical care.

**Sex abuse**
- Child makes a disclosure.
- Child displays sexualized behaviors.
- Doing something with being something about private parts.
- Doing something that looks like sex or talking about sex.
- Child has genital injury or infection.
- Any pregnancy in child with years end.

Medical history
- When > 5 years old, ask open-ended questions that do not introduce concepts of abusive acts or abuse. For children > 5 years old, assure information away from the child's presence if possible.
- For all questions, listen attentively, BELIEVE them, and thank them for telling you. Reassure them and avoid any anger because the child may misinterpret this as you being angry at them.

1. Obtain a focused injury history (especially timeline).
2. Review past medical history, including prior trauma, injuries, surgeries, and hospitalizations.
3. Family history (bloodline, including concerns, heredity, or genetic issues).
4. Developmental and behavioral health history.
5. Social history: where they live, who they live with (including OTHER CHILDREN in household), substance use/abuse, job loss, other stressors, etc. Current social worker in place.

*Note: History is the most important part of this entire process.*

Physical examination
1. General assessment—height, weight, temperature, special, sensitivity, growth (pubertal, awake, palpation, neurological, wound care, injury, etc.).
2. Complete head to toe skin examination, looking for bruises, lacerations, burns, bites, etc. This includes and evaluation of cardiovascular, respiratory, abdominal, neuromuscular, and psychosocial. If possible, the examining provider should conduct a thorough physical examination, even if performing patient or adolescent. At times, a specialist should conduct a thorough examination, even if referring patient to specialist.

- Only secure cameras should be used to photograph patients. This typically includes patients with fetal abnormalities.
- If photographs are needed, pass contact local social services or child abuse team.

Diagnostic testing for suspected child abuse

---

**Age 0–6 months**
1. Child protective team consult.
2. Blood (PT and PTT).
3. Lab: AST, ALT.

**Age 6–24 months**
1. Child protective team consult.
2. Kidney survey.
3. Lab: AST, ALT.
5. Urine for high GGT or MRI.

**Age > 24 months**
1. Consider child protective team consult.
2. If > 5 years old, consider history team involved.
3. Continue lab evaluation:
   a. AST, ALT
   b. Urine toxicology

If unexplained:
- Blood tests: send CBC, PT, and PTT.
- Fractures—send Ca, Mg, phosphates.
- Sex abuse: send PT, 25-OH vitamin D.

Management
1. Referral to investigation agencies/child protection agencies according to state-specific mandated reporting laws. State reporting statutes and other resources available from Child Welfare Information Gateway or the Child Abuse and Neglect (CCSM) website: asp.legislature.ca.gov/CCSM. Additional information on child abuse and neglect (CCSM) website: asp.legislature.ca.gov/CCSM.
2. Referral to appropriate medical providers (such as a pediatric trauma center). Referral to appropriate behavioral health evaluators for trauma symptom screening and education. Early mental health interventions (within the first 30 days following a traumatic event). Additional information on resources: NC. Child Traumatic Stress Network webpage (http://www.cert.org/resources).
4. Safety plan in place for discharge with appropriate follow-up plan. This may require coordination with local social services.

Sasha Svendsen, MD and Peter J. Sell, DO
CHRONIC JOINT PAIN AND STIFFNESS

Jonathan W. Smits, MD, James McKee, DO, MS, and J. Herbert Stevenson, MD

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD), DIAGNOSIS AND TREATMENT

Suspect COPD if:
- Chronic cough and/or sputum production
- History of smoking or exposure to noxious particles or gases
- Dyspnea at rest and on exertion

Spirometry with pre- and postbronchodilator

Severity of COPD

- **FEV₁/FVC**
  - **FEV₁**
    - Mild: <0.7
    - Moderate: 0.7 to 0.8
    - Severe: ≤0.8
    - Very severe: ≤0.5

**Functional Dyspnea Scale**

0 - Not troubled with breathlessness except with strenuous exercise
1 - Troubled by shortness of breath when hurrying or walking up a slight hill
2 - Walks slower than people of same age due to breathlessness or has to stop for breath when walking at own pace on level
3 - Stopped or breathless after walking 100 m or after a few minutes on the level
4 - Too breathless to leave the house or breathless when dressing or undressing

**Diagnosis confirmed, initiate preventative measures:**
- influenza vaccine (yearly), 23-valent pneumococcal vaccine once before age of 65 years and every 5–10 years until age of 65 years; 23-valent and 13-valent pneumococcal vaccine once after age of 65 years

Aggressive smoking cessation counseling if actively smoking

**Mild Group A COPD**
- FEV₁ >80% predicted
- FDS: 0 or 1
- 0–1 exacerbation per year

Treatment:
- Short-acting β₂-agonist or anticholinergic PRN

**Moderate Group B COPD**
- FEV₁ 60% to 80% predicted
- FDS: 1
- 1 exacerbation per year

Treatment:
- Long-acting β₂-agonist or long-acting anticholinergic
- Short-acting β₂-agonist PRN

**Severe Group D COPD**
- FEV₁ <60% predicted or <50% predicted
- FDS: 2 or 3
- 2 exacerbations per year or 1 exacerbation leading to hospitalization

Treatment:
- Inhaled corticosteroids plus long-acting β₂-agonist
- Long-acting anticholinergic
- Inhaled oxygen supplementation
- Assess for supplemental oxygen, if
  - Short-acting β₂-agonist plus long-acting anticholinergic combination
  - Long-acting β₂-agonist plus long-acting anticholinergic combination
  - Consider Azithromycin in patients with frequent exacerbations

**Very Severe Group D COPD**
- FEV₁ <30% predicted or <40% predicted
- FDS: ≥4
- ≥2 exacerbations per year or ≥1 exacerbation leading to hospitalization

Treatment:
- Inhaled corticosteroids plus long-acting β₂-agonist
- Long-acting anticholinergic
- Pulmonary rehabilitation
- Assess for supplemental oxygen
- Consider surgical options and/addition of a phosphodiesterase-4 inhibitor
- Long-acting β₂-agonist plus long-acting anticholinergic combination
- Long-acting β₂-agonist plus oral glucocorticoids
- Consider Anticholinergic in patients with frequent exacerbations

*Supplemental oxygen determination:
- PaO₂ ≤56 mm Hg or SaO₂ ≤88% OR
- PaCO₂ ≥59 mm Hg or SaO₂ ≤88% AND symptoms of cor pulmonale, right heart failure, or Hct <38%*

No

- Continue current treatment

Yes

- Consider long-term supplemental oxygen therapy
William W. Wong, DO and Scott E. Kopec, MD
CIRRHOSIS

Common causes: alcohol abuse, viral hepatitis, 
α1-antitrypsin deficiency, 
collagen vascular disease, nonalcoholic 
steatohepatitis, hemochromatosis, medications, 
primary biliary cirrhosis, primary 
sclerosing cholangitis

Check liver function tests, HepAAb, 
HCV Ab, HBsAg, HBsAb, Fe, TIBC, 
terrin, OSBC w/diff, monospot, ANA, CRP, 
antimicrosomal antibodies (AMA's), US

syndrome

CONCUSSION, SIDELINE EVALUATION

Concussion: traumatic event and/or change in neurologic function OR one of the following signs/symptoms: somatic (headache, nausea/vomiting, nausea/vomiting [N/V], dizziness, vertigo, visual problems, sensitivity to light or sound, numbness/lingual, cognitive [LOC, memory problems, feeling "foggy," slower reaction times, confusion, emotional/behavioral fill, e.g., irritability, sadness], sleep fill, i.e., insomnia).

Evaluate ABCs and check for C-spine injury. Remove from play.

Bible and normal C-spine exam. Unstable or C-spine injury possible.

Obtain history: including mechanism of injury, risk factors (previous concussion, younger age, female), and clinical presentation.

Patient should undergo physical and cognitive test while symptoms present.

No major symptoms, review Return to Play protocol.

If at neurologic baseline, consider EO evaluation or neuropsych testing (e.g., MMSE, NAP, etc.).

The ideal timing, tempo, and type of neurocognitive testing have not been determined.

Many concussions can be managed safely without the use of neurocognitive testing.

Neurocognitive testing may be most helpful for high-risk athletes. Those with prior concussions, and those who may display symptoms in an effort to return to play sooner.

C.

Once the patient is tolerating visual and auditory stimuli for 30–45 minutes, they may return to school.

Visual stimuli such as a favorite visual tool or novel visual stimuli may be necessary while returning.

Return to Play process.

No athlete may return to play the same day.

No athlete may return to school/activity until cleared by physician.

No athlete should be on any medications to treat concussion symptoms before returning to play.

Once asymptomatic at 6 hours, they may return to next stage if symptoms are minimal and normal C-spine exam is normal. No school-dropout back to play until full symptom status.

When athlete is cleared, should return to 7 days after concussion.

Stage 1: Activity (complete physical AND cognitive rest, cognitive rest includes reading).

Stage 2: Light activity (walking, swimming, or light physical activity at <30% max HR)

Stage 3: Sport-specific exercise (light activity, regenerative exercises: jogging, running, or low impact aerobic activity).

Stage 4: Noncontact training drills (progression to more complex training drills such as passing, may start progressive resistance training).

Stage 5: Full, non-contact participation.

Stage 6: Return to play.

For students and athletes of younger age or more than 4 days after, consider delaying return to school and activity.

Symptom management: if concussive symptoms persist beyond 7–10 days, consider neurocognitive testing.

Kaleigh Timmins, MD and Frank J. Domino, MD
Frank J. Domino, MD

CONSTIPATION, DIAGNOSIS AND TREATMENT (ADULT)

Daniel J. Stein, MD, MPH and Stephen K. Lane, MD
 CONSTIPATION, TREATMENT (PEDIATRIC)

- **Rome III Criteria (≥2 criteria):**
  - ≥2 defecations per week
  - At least one episode of incontinence per week after toilet training
  - History of excessive stool retention
  - History of painful/urgent bowel movements
  - Presence of a large fecal mass
  - History of large distal stools that may obstruct the bowel

- **Red flags:**
  - Constipation <1 month of age
  - No meconium in 48 hours
  - Family history of Hirschsprung disease
  - Ribon stools
  - Blood in the stools without anal fissures
  - Failure to thrive
  - Fever
  - Bilious vomiting
  - Abnormal tympany
  - Severe abdominal dissection
  - Perianal fistula
  - Abnormal position of anus
  - Abnormal anal or perianal reflex
  - Decreased lower extremity tone
  - Tuft of hair on spine
  - Sacral dimple
  - Generalized cleft deviation
  - Extreme fear during anal inspection
  - Anal scar

---

**Diagnostic Evaluation:**

- Careful history and physical exam; digital rectal exam is not required for diagnosis.

**Fecal Incontinence:**

- **Yes**
  - Obtain based on symptoms: CBC, TSH, calcium, glucose, creatinine, tissue transglutaminase (TG), and endomysium antibody (EMA)

- **No**
  - Functional constipation

**Differential Diagnosis:**

- Celiac disease
- Hypothyroidism
- Hypercalcemia
- Hypokalemia
- Diabetes mellitus
- Drugs (opioids, anticholinergics, antidepressants, chemotherapy, and heparin)
- Vitamin D intoxication
- Urethral orifice
- Hirschsprung disease
- Anal atresia
- Colonic inertia
- Anal malformations
- Pilonidal sinus
- Spinal cord abnormalities
- Abnormal abdominal musculature
- Pseudoobstruction
- Multiple endocrine neoplasia type 2D

**First Line Therapy:**

- Polyethylene glycol 3350: 1-4.5 g/kg/day for 3-5 days

**Second Line Therapy:**

- Mineral oil daily

**Maintenance Therapy:**

- PEG 0.4 g/kg/day adjusted for one to two soft bowel movements per day

**Lactulose is acceptable if PEG is not available.**

**Dietary/Lifestyle Recommendations:**

- Normal diet intake
- Normal fluid intake
- Normal physical activity
- No restrictions for use of pro or prebiotics

Amanda E. White, DO, MBA and Kelley V. Lawrence, MD, IBCLC, FAAFP, FABM

Shannon Roche, DO and Sara Casey, DO
DEEP VENOUS THROMBOSIS, DIAGNOSIS AND TREATMENT

Determine Wells score
- Active cancer +1
- Calf swelling >3 cm +1
- Collateral superficial veins +1
- Pitting edema +1
- Previous DVT +1
- Pain along venous system +1
- Paralysis or recent immobilization (cost) +1
- Recently bedridden for >3 days or general anesthesia +1
- Recent diagnosis of DVT +1
- <1 DVT unlikely
- ≥2 DVT likely

Scoring

≥0: low probability
1 or 2: Intermediate probability
≥3: high probability

D-dimer
Negative
DVT ruled out
Positive
D-dimer
Negative
DVT ruled out
Positive
DVT confirmed

D-dimer
Negative
DVT ruled out
Positive
Consider repeating US in 5–7 days.

Any respiratory symptoms:
- Proximal VTE
- Candidate for thrombolysis
- Active bleeding
- Renal failure
- History of HIT
- Severe cyanosis or ecchymosis

Outpatient management (See next page)
Admit (See next page)
Treatment

Outpatient management

- Low-molecular-weight heparin (LMWH):
  - Enoxaparin 1 mg/kg SC BID or
  - Dalteparin 200 IU/kg SC daily for patients with cancer
  - LMWH is the preferred treatment in pregnancy.

- Reversal agents (factor Xa inhibitors):
  - 15 mg BID with food for 3 weeks followed by 20 mg daily for 6–12 months
  - Contraindicated in patients with active pathologic bleeding or history of severe hypersensitivity reaction to the drug
  - Avoid in patients with CrCl < 30 mL/min.
  - Use is not recommended in pregnancy or breastfeeding.
  - Current use is limited due to cost and lack of reversal agent.

Maintenance therapy

- Hypercoagulable test before starting anticoagulation therapy
- UFH is preferred in patients with renal impairment.
- Treatment with LMWH, UFH, or fondaparinux is recommended for at least 5 days AND until INR ≥ 2 for 2 consecutive days.
- Start warfarin on same day as LMWH, UFH, and fondaparinux.
  - Goal INR 2–3
  - Continue for 3–6 months after first DVT
  - Warfarin is contraindicated in pregnancy.
- Rivaroxaban 20 mg daily for 6–12 months
- Dalteparin (direct thrombin inhibitor): 150 mg BID after 7–10 days of LMWH and continue for at least 3 months
  - Adjust dose for CrCl < 50 mL/min.
  - Do not use in CrCl < 15 mL/min.
  - Contraindicated in active pathologic bleeding, history of severe hypersensitivity reaction to the drug, and mechanical prosthetic heart valve.
  - Use is not recommended in biventricular heart valve, pregnancy, and breastfeeding.
- LMWH or heparin SC can be continued for patients with allergy to warfarin.
- Consider IVC filter for individuals with contraindication to anticoagulation.

Inpatient management indications

- Massive DVT
- Symptomatic PE
- High-risk bleeding with anticoagulation therapy
- Comorbid conditions

- IV unfractionated heparin (UFH): 80 U/kg bolus or 5,000 U — continuous infusion with initial dose 18 U/kg/h → titrate to goal
  - PTT 60–85 seconds or
  - UFH 250 U/kg SC BID or
  - Enoxaparin 1 mg/kg SC daily or
  - Fondaparinux 5–10 mg SC daily depending on weight.

Bency K. Louidor-Paulynice, MD
DEHYDRATION, PEDIATRIC

Causes of dehydration in pediatric patients include gastrointestinal losses (vomiting, diarrhea), losses from skin (sweat, fever, burns) and urinary losses (glycosuria, diabetes).

Determine severity of losses:
1. Examine weight present for comparison: 1 gram of weight loss = 1 milliter of water lost.
2. Use clinical assessment to determine severity of dehydration

<table>

Patient has circulatory instability or shock, altered mental status, intractable vomiting, bloody diarrhea or ileus, abnormal serum sodium values, or glucose malabsorption?

Oral Rehydration with oral replacement solution

Deficit replacement: 50 to 100 mL/kg body weight every 2 to 4 hours in frequent small amounts (tcp or dropper)

Maintenance: With oral replacement solution:
<10 kg: 4 mL/kg
11-20 kg: 40 mL + 2 mL/kg (per kg 11-20)
>20 kg: 60 mL + 2 mL/kg (per kg >20)

Ongoing losses:
Give 10 mL/kg per loose stool, 2 mL/kg per episode of emesis

Treat for hyponatremic or hypernatremic dehydration

Simult Na 120–150 mEq/L?

Yes

Parenteral Rehydration: 20 mL/kg (solution of 0.9% Na)

No

Fails oral rehydration

Emily Sherrard, MD and Sarah Hinton, MD

DEMENTIA

Common causes:
- Alzheimer disease
- Vascular dementia
- Low body dementia
- NPH, HIV, depression

Concern for cognitive impairment:
- Perform a cognitive screen with a validated tool (the Mini-Cog [Mini-Cog tool], Mini-Mental State Examination [MMSE], Montreal Cognitive Assessment [MoCA]).

Failed screen

- Yes
  - Laboratory studies:
    - Routinely recommended: TSH, vitamin B12, CMP, CBC, folate
    - High clinical suspicion: syphilis testing, HIV, UA, heavy metals, LP

- No
  - Consider medication side effects: antianxiety, anticholinergics, psychotropics, sedatives, benzodiazepines, etc.

Positive

- Abnormal labs
  - Thyroid disorder
  - Vitamin B12 deficiency
  - Electrolyte abnormalities
  - Uremia
  - Folate deficiency
  - Syphilis
  - HIV

- Consider imaging:
  - CT or MRI (depending)
  - Abnormal or rapid decline
  - Age <60 years
  - Predisposing condition (malignancy, anticoagulation)

Negative

- Normal labs

- Abnormal
  - Vascular dementia (sporadic decline)
  - Normal-pressure hydrocephalus (gait disturbance, incontinence)
  - Pick disease (personality change)
  - Subdural hematomas

- Normal
  - Alzheimer disease
  - Parkinson disease
  - Frontotemporal dementia
  - Low body dementia
  - Chronic alcohol use

Konstantinos E. Deligiannidis, MD, MPH, FAAFP
### Depressive Episode, Major

**Obtain symptom score using PHQ-9:**
1. Depressed mood
2. Loss of interest/pleasure
3. Change in sleep
4. Change in appetite or weight
5. Change in psychomotor activity
6. Loss of energy
7. Trouble concentrating
8. Thoughts of worthlessness or guilt
9. Thoughts about death or suicide

Determine and document DSM-5 criteria for MDD.
*Presence of symptoms 1, 2, or both, plus 5 or more symptoms during the same 2-week period leading to dysfunction.*

**Depression screen:**
- Depressed mood and/or loss of interest/pleasure most days, most of the day >2 weeks

**Imminent risk of serious self-harm/suicide?**
- No
- Yes: Refer to emergency mental health for treatment and stabilization.

**Medications:**
1. Comorbid medical condition, substance abuse causing depression?
   - Yes: Provide medical treatment (including substance abuse treatment) and follow-up.
   - No
2. History of treatment-resistant depression, current mania, hypomania, or psychosis?
   - Yes: Refer to mental health specialty care.
   - No
3. Determine symptom severity and functional impairment.

**Severity**
- Mild: PHQ-9 score 10–14
- Moderate: PHQ-9 score 15–19
- Severe: PHQ-9 score >20

**Mild**
- Start with monotherapy of either antidepressant or psychotherapy referral.

**Moderate**
- Use a combination of both antidepressant and psychotherapy.

**Severe**
- Emphasize combination of both antidepressant and psychotherapy; may consider multiple drug therapy, or referral to psychiatrist or inpatient stabilization.

**Improvement in 2-3 weeks?**
- No: Increase dose, change antidepressant, or add therapy. Maximum benefit from a given dose can take 10 weeks.
- Yes
  - Maintaining effective treatment; follow up q1–2w PHN.

**If 2 or 3 antidepressants trialed ineffective or patient status worsening**
- Refer to psychiatrist.

FATIGUE

Chief complaint: “Fatigue”

Common causes: depression, anxiety, substance abuse, medication, viral illness, thyroid dysfunction, obstructive sleep apnea, CMD

Perform thorough history:
History of present illness, social (stress, substances, safety, support), occupational (work exposure, work activities), lifestyle (sleep, diet, exercise, housing, environmental exposures), family history, medication reconciliation

Ask patient: what does “fatigue” mean for you?

Lack of energy

Sleepiness

Weakness

Shortness of breath

Unspecified or none of the above

Consider: depression; chronic illness; infectious cause (hep C, EBV, cytomegalovirus), medication side effects, multiple sclerosis, malignancy, anxiety, substance abuse

Consider: obstructive sleep apnea, inadequate sleep

Consider: neurologic disease, myopathy (caused by endocrinopathy, autoimmune disease)

Consider: cardiac anemia, CHF, anemia, ischemia

Initial workup:
Vitals, physical exam (heart, lungs, neuro, psychiatric, thyroid exam, diabetes, Hct, PMSR, UA)
Basic labs (Hgb, CBC, urine HCG, TSH, ERP/P, UA)
Additional labs if relevant (W&L, ferritin, vit D, Ca, creatinine, vitamin screenings, urine drug test)

Likely diagnosis found?

No

Yes

Continue appropriate workup and management

Return to top of algorithm. Repeat initial evaluation in 1-3 months

Follow up 1-3 months

Likely diagnosis found?

No

Yes

Initial management: adequate sleep, exercise therapy, shift focus to managing symptoms, mental health evaluation

Diagnostic outcome for “fatigue”:
- 20% MSK
- 17% Psych
- 8% Medical
- 5% Other
- 50% No clear diagnosis

*Tests of low utility in absence of additional relevant history or exam findings (Vit D, Vit B12, heavy metal toxicity, Lyme, IL-6, cytomegalovirus, Celiac workup)
**Additional specific testing not recommended in absence of localizing symptoms

Judy Wang, MD and Stacy Potts, MD, MEd
FEVER IN FIRST 90 DAYS OF LIFE

Laura Y. Mercurio, MD and Robyn Wing, MD, MPH
FEVER OF UNKNOWN ORIGIN

Common causes:
infection, malignancy, inflammatory
disease, transfusion reaction, sarcoidosis, medication

Locating abnormalities/symptoms?
Yes
Focused diagnostic testing

No
Discontinue implicated medications.

Recent hospitalization?
Yes

No

Check: fever, extremity edema, CT angiogram.
Check: abnormal white blood cell count, spread streaks.
Check: HIV, CBC with diff, ESR, CRP, ferritin, LDH, LFTs, blood culture, urine culture, GFR, PPD/QF/IRON-T Providers

Deep vein thrombosis, pulmonary embolism
C. difficile infection

HIV+

HIV- Yes
HIV positive

Opportunistic bacteria
HSV
Pneumocystis
Aspergillus

PJP pneumonia, CMV, HPV, Lymphoma, TB, MM, Toxoplasmosis, Fungal Infection

Malignancy suspected

Nonhematologic
Hematologic

Autoimmune condition suspected

Check: sputum cultures, MRI, ASO/ACM/EVL, etc.

Check: TTE, abdominal/pelvic/retroperitoneal CT, PET scan, kumaric puncture.

Check: brain MRI, biopsy (skin, lymph, liver, excretory urography).

Check: bone marrow biopsy.

Chronic infection suspected

Check: rheumatoid factor, ANA, ACE, TSH.
GASTROESOPHAGEAL REFLUX DISEASE (GERD), DIAGNOSIS AND TREATMENT

Hadi Atassi, DO and Thomas L. Abell, MD
Chidinma Osineme, MD
**HEADACHE, CHRONIC**

Red Flag Symptoms:
- >60 at age of onset
- acute onset, thunderclap headache
- new headaches:
  - significant change in characteristics of prior headache
  - signs or symptoms of systemic illness
  - neurologic symptoms not consistent with typical euro symptoms
  - non-systemic illness that predisposes to secondary headache
  - headaches associated with maneuvers that increase or decrease intracranial pressure

Possible causes:
- Subdural bleed
- Epidermal bleed
- Tumor

Chronic migraine:
- (1) ODH for at least 4 months; (2) on >6 days/month for at least 3 months, headache fulfills criteria for migraine without aura and/or treated and relieved by triptans or ergots, and (3) no medication overuse or secondary cause.

Chronic tension-type headache:
- (1) headache lasting hours with >2 of characteristic features (pressing/tight, bilateral, or not aggravated by activity); (2) Only 1 of photophobia, phonophobia, or mild nausea and no moderate or severe nausea/vomiting

New daily persistent headache:
- headache developing within 3 days of headache onset that is unrelenting for >3 months

Hemicrania continua:
- Daily, continuous, strictly unilateral primary headache disorder that is associated with cranial autonomic features (flushing, ptosis, eyelid edema, lacrimation, nasal congestion or rhinorrhea)

Medication overuse headache:
- head, triptan, ergot or beta-blocker analgesic taken on a regular basis >10 days/month, other non-opioid analgesics >15 days/month, or a total exposure of all acute drugs >15 days/month

Concordant features on imaging:
- Neuroimaging

Lifestyle modifications:
- sleep pattern regulation, diet, exercise, weight loss and reduction of caffeine intake

Physical therapy, acupuncture, biofeedback, relaxation therapy and cognitive behavioral therapy

Pharmacologic therapy:
- (1) long-acting NSAIDs (naproxen, diclofenac, ketoprofen, or celecoxib); (2) acute abortive therapy (DHE, sumatriptan); (3) DHE, greater endorphin nerve block

Prophylactic therapy:
- Anticonvulsants (divalproex sodium, topiramate, gabapentin), tricylic antidepressants, beta blockers, calcium channel blockers, verapamil, sartan antagonists (candesartan), and NSAIDs magnesium sulphate

Oralabixin: A injections

**Linh Hoang, MD and Crystal Nwagwu, MD**

Navpreet Singh, MD and Inderjit Singh, MD

HEMATEMESIS (BLEEDING, UPPER GASTROINTESTINAL)

Sirmad B. Chaudhary, MD and Kristine J. Krueger, MD
HEMATURIA

Risk factors for urinary tract malignancy:
- Age >35 years
- Male sex
- Analgesic abuse
- Exposure to chemotherapeutic agents
- Past or current smoking
- Chronic UTI
- Pelvic irradiation

Common causes:
- Cystitis, urethritis, pyelonephritis, tumor, prostatitis
- Hb & urinalysis centrifuge
- Supernatant red
- Dipstick supernatant
- Sediment red
- Hematuria
- Beuturia, phenazopyridine, proctitis
- Heme-negative
- Heme-positive
- Plasma color
- Clear
- Red

Microscopic urinalysis
- <3 RBCs/HPF
- Repeat UA 3 times at 6-week intervals
- Negative
- Repeat UA 6 weeks after flu and discontinuation of contributing factor
- No tumor workup
- Negative

Assess for UTI: vigorous exercise, menstruation, recent urologic procedure
- Positive
- Dysmorphic RBCs, proteinuria >500 mg/dl

Low risk for malignancy, renal insufficiency:
- US/contrast CT and urology referral
- Annual UA for 2 years
- Negative
- Repeat annual evaluation in 3–5 years
- Release from care

High risk for malignancy, normal renal function:
- Cystoscopy
- CT with IV contrast and urology referral
- Negative
- Positive
- Treat
- Repeat anatomic evaluation in 3–5 years

Assess for risk factors for malignancy, renal insufficiency:
- Nx
- Oxidant complement levels, C3, C4
- Low
- Systemic diseases
- Lupus, cryoglobulinemia, bacterial endocarditis, glaucoma
- Renal
- PAN, GPA, HSP, QP, hyperreactivity, vasculitis
- IgA, idiopathic MPGN, anti-GBM, pauci-immune

Krishna Manda, MD, MRCP and Jagathi Govindu, MD

HEPATOMEGALY

Common causes: liver disease, obesity (nonalcoholic fatty liver disease), and steatohepatitis, neoplasms, infection, vascular disease, fatty liver, storage disorders, biliary disease, toxins, metabolic disturbances, anatomic variation (Reidel's lobe)

History: Evaluate for heart failure, obesity, alcohol use, infections, genetic diseases, recent exposure, medications and travel

Initial Labs: ALI/AST
Total bilirubin (indirect/Direct)
Alkaline phosphatase
Hepatitis serology
PT/INR
Serum albumin

Abnormal

Imaging: CT, ultrasound

Normal

Liver biopsy

Cholestatic injury: predominant elevation of bilirubin and alkaline phosphatase

Primary sclerosing cholangitis
Primary biliary cirrhosis
Malignancy
Biliary obstruction

Vascular congestion: Hepatic congestion secondary to heart failure
Budd-Chiari syndrome
PV/IVC obstruction

Nonalcoholic fatty liver disease
Liver biopsy +/- transaminase

Vascular

Cyst

Pyogenic liver abscesses usually develop following portal or direct spread of biliary infection

Primary liver tumor (benign or malignant)
Metastatic liver disease
Granulomatous liver disease (TB, sarcoidosis, etc.)

Consider percutaneous drainage/tapping

Nonalcoholic fatty liver disease

Medications/toxins:
Acetaminophen
Statin
Illicit drug reaction
Mushroom poisoning

Other:
Autoimmune hepatitis
Wilson disease
Alpha-1-Antitrypsin deficiency
Hemochromatosis
Nonalcoholic fatty liver disease
Alcoholic hepatitis

Liver is normal, nontender in 3 months.

Malignancy

Consider the following diagnoses:
Cirrhosis
Alpha-1-Antitrypsin deficiency
Chronic hepatitis
Hemochromatosis
Glycogen and fat storage disease (pseudotumor carriers)
Extrahepatic hematopoiesis
Malignancy
Biliary obstruction
Nonalcoholic fatty liver disease

Francis Carro-Cruz, MD and Marie L. Borum, MD, EdD, MPH, MACP, FACP, AGAF

HYPERBILIRUBINEMIA AND JAUNDICE

Jaundice: a yellow discoloration of skin, sclera, and mucous membrane by bilirubin, a bile pigment formed by the breakdown of heme rings; detected when the serum bilirubin level > 3 mg/dL.

Bilirubin is a product of hemoglobin breakdown in the spleen. It is converted to unconjugated bilirubin, bound to albumin, and then sent to the liver where it is then conjugated.

Common causes: Gilbert syndrome, hemolysis, hepatitis, and cholestasis.

CBC w/diff, LFTs: ALT, AST; serum alkaline phosphatase (AP); total bilirubin (TB); and direct bilirubin (DB), haptoglobin, hepatitis serologies, amylase, lipase, HCG, urinalysis with urine bilirubin; US or CT.

Unconjugated hyperbilirubinemia

- Direct bilirubin > 0.3 mg/dL

Conjugated hyperbilirubinemia

- Obstruction or imaging

- Extrahepatic cholestasis (tends: elevated TB and DB; elevated AP; and positive urine bilirubin. US shows dilated bile ducts)
  - Cholestasis: infection; chronic pancreatitis; alcohol; sclerosing cholangitis
  - Cholangitis: fever, pain, jaundice, altered mental status, sepsis
  - Primary biliary cirrhosis: history of surgical/endoscopic procedure
  - Primary sclerosing cholangitis

- Extrahepatic types
  - Tumor (carcinoma, melanoma, others)
  - Intrahepatic cholestasis (tends: elevated TB and DB; elevated AP; and positive urine bilirubin. US shows normal sized bile ducts)
  - Others
    - Medication induced
    - Total parenteral nutrition (TPN)
    - Sepsis
    - Sarcoidosis
    - Pregnancy

Unconjugated hyperbilirubinemia

- Gilbert syndrome: mild defect in UDP-glucuronyltransferase (UGT), responsible for conjugation of bilirubin
- Crigler-Najjar syndrome: more severe defect in UGT, usually presents during infancy

Conjugated hyperbilirubinemia

- Dubin-Johnson syndrome: defective secretion of conjugated bilirubin
-Rotor syndrome

Both conjugated and unconjugated hepatoellular injury:

- Hepatitis: viral, alcoholic, or autoimmune
- Intrahepatic cholestasis: inflammation that impairs or prevents transport/sequestration of conjugated bilirubin
- Medication-induced: acetaminophen
- Cholestasis
- Congestive liver failure
- Hypoalbuminemia of hepatoecytose leads to cellular injury

Intrahepatic cholestasis (and elevated LFTs, primarily AP); US shows normal sized bile ducts.

Others:

- Medication induced
- Total parenteral nutrition (TPN)
- Sepsis
- Sarcoidosis
- Pregnancy

Krunal Patel, MD and Gustavo Churrango, MD
HYPERCALCEMIA

Common causes: hyperparathyroidism, malignancy, hyperthyroidism, vitamin D toxicity, milk-alkali syndrome, medications.

Obtain ionized calcium or total calcium:
Corrected Ca = total Ca × 0.8 × (4.5 – albumin level).

Clinical suspicion:
Signs and symptoms of hypercalcemia:
- GI: nausea, vomiting, anorexia, and constipation
- Neurologic: lethargic, hypotonic, confused, or comatose
- Renal: polyuria, nephrocalcinosis, and denudation
- Cardiac: shortened heart rate–corrected QT intervals, broadened T waves, and 1st-degree atrioventricular block

Review medications:
- Increased calcium intake, vitamin A intoxication, vitamin D overdose, thiazides, milk-alkali syndrome, theophylline, lithium

Check parathyroid hormone.

Blunted PTH

- Consider ectopic secretion of PTH (e.g., ovarian carcinoma).

Measure urinary calcium.

- Elevated
  - Consider familial hyperparathyroidism.
  - Consider surgery.
- Low
  - Consider primary hyperparathyroidism.
  - Obtain detailed family hx.

Normal PTH or low

- PTH-related protein (PTHrP) and 25-OH vitamin D and 1,25 OH vitamin D

Elevated PTHrP

- Consider malignancy
  - Neoplastic hypercalcemia of malignancy (i.e., squamous cell carcinomas) OR local osteolytic hypercalcemia (i.e., multiple myeloma, bone metastases).

Elevated 1,25 OH vitamin D

- Consider endogenous production from granulomatous disease or lymphoproliferative disorders (i.e., TB and sarcoidosis).

Normal or low 1,25 OH vitamin D

- Consider thyrotoxicosis, prolonged immobilization.

Elevated 25-OH vitamin D

- Consider supplemental vitamin D overdose.

Revise medications.

Deborah A. Lardner, DO, DTM&H and Michael Passafaro, DO, DTM&H, FACEP, FACOEP

HYPERKALEMIA

K > 5.5 mEq/L

Common causes: renal failure, hyperglycemia, specimen delay and hemolysis, renal insufficiency, sepsis, rhabdomyolysis, insulin deficiency, adrenal insufficiency, medications, massive blood transfusions, tumor lysis, ischemic bowel

Weakness, nausea, paresthesias, palpitations, ileus, fasciculation

ECG changes: peaked T waves, PR interval, QRS width, sine wave pattern, PE

Repeat test.

No

Yes

Normal

Abnormal

Check medications.

Treat as acute hyperkalemia.

Pseudohyperkalemia: IVF with K, hemolysed sample

ACEI, ARBs, a-blockers, NSAIDs, penicillin K, TMP-SMX, digoxin, K-sparing diuretics, heparin, cyclosporine, tetracycline, pentamidine, eucaryochrome

No

Yes

No suspicious medications

Discontinue medication or adjust dose.

ABGs, GFR, Cr, BUN, glucose, electrolytes, digoxin levels, CKP, urine K+

Urine K < 30 mEq/L; transcellular shift

Acidosis

Rhabdomyolysis

Burns

Renal insufficiency

Adrenal insufficiency

Hyperparathyroidism

Hyperaldosteronism

Urine K < 30 mEq/L; impaired renal excretion

Samuel Tiglao, DO and Karla Vega Colon, MD
HYPERLIPIDEMIA

Abbreviations
ACS: Acute coronary syndrome
ASCVD: Atherosclerotic cardiovascular disease
CABG: Coronary artery bypass graft
cCrl: Coronary artery calcification
CKD: Chronic kidney disease
DM: Diabetes mellitus
eGFR: Estimated glomerular filtration rate
HIV: Human immunodeficiency virus
LDL-C: Low-density lipoprotein cholesterol
PCI: Percutaneous coronary intervention
PCSK9: Proprotein convertase subtilisin/kexin type 9 inhibitor

Primary Prevention
Encourage healthy lifestyle to reduce lifetime ASCVD risk
Measure LDL-C

Secondary Prevention
Encourage healthy lifestyle to reduce lifetime ASCVD risk

Does patient have established ASCVD?

Start high-intensity or maximally tolerated statin
Assess adherence and LDL-C % reduction 4 to 12 weeks after initiating therapy

LDL-C ≥190 mg/dL

Yes

LDL-C ≥100 mg/dL or >50% reduction from baseline?

Yes

LDL-C ≥70 mg/dL

Consider moderate or high-intensity statin when initiating therapy in patients aged ≥75 years.

LDL-C ≥100 mg/dL or >50% reduction from baseline?

Yes

Consider adding ezetimibe
Ezetimibe 10 mg once daily

Yes

No
Jason E. Cross, PharmD, Dinesh Yogaratnam, PharmD, and Sudeep K. Aulakh, MD

HYPERNATREMIA

Sodium >145 mEq/L

History and review states

Hypovolemic
- Dermal losses
- GI losses
- Diuretics
- Postobstruction
- Acute and chronic renal disease
- Hyperosmolar nonketotic coma

Euolemic
- Diabetes insipidus (central, nephrogenic)
- Hypodipsia
- Fever
- Hyperventilation
- Mechanical ventilation

Hyperosmolar
- Intoxicogenic (hypertonic saline infusion, oral fluid intake, antidiuretic therapy, salt-containing antiemetics)
- Hyperglycemia
- Cushing's disease

If cause is not clear from history, obtain a urine and plasma osmolality and urinary sodium.

Urine osmolality/plasma osmolality <207 mOsm/kg

Diabetes insipidus (central, nephrogenic)

Hypovolemic

Hypovolemic

Urine osmolality/plasma osmolality >207 mOsm/kg

Urine sodium >20 mEq/L

Renal
- Diuretics (osmotic, loop)
- Intestinal renal disease
- High protein diet

Endocrine
- Cushing disease
- Primary hyperaldosteronism
- Diabetes mellitus

GI losses
- Laxatives
- Malabsorption
- Infections

Respiratory losses
- Hyperventilation

Skin losses
- Excessive sweating

Timothy J. Coker, MD, FAAFP

HYPERTRIGLYCERIDEMIA

Steven W. Gale, MD and Timothy J. Coker, MD, FAAP
HYPOALBUMINEMIA

Albumin <3.5 g/dL

History: edema, jaundice, ascites, nephrotic, foamy urine, muscle atrophy, edema, weight gain, loss of appetite, malnutrition, decreased PO intake, hyperlipidemia, diarrhea, vomiting, burns, inflammation

Decreased protein synthesis

Cirrhosis, etioglossine, ascites, edematous angiomata

Hypoalbuminaemia

Acute and chronic inflammation

Diabetes

PLT <160,000/mm³, elevated LFTs (e.g., AST), positive hepatitis INR ≥1.5, elevated GGT, alkaline phosphatase, nodular liver on abdominal US

Decreased lymphocyte count, BUN, transferrin, prealbumin

Malnutrition and starvation

Lawrence M. Gibbs, MD, MSED, FAAFP

HYPOCALCEMIA

Common causes: lab error, chronic renal failure, postsurgical hypoparathyroidism, hypocalcemia, hypomagnesemia, hyperphosphatemia, medication, PTH deficiency or resistance, vitamin D deficiency or resistance.

Check labs: Repeat serum calcium, ionized calcium, electrolytes, BUN, creatinine, magnesium, phosphorous, albumin, FT4, PT, PTT, PTH.

Serum calcium >8.5 mg/dL

Probable false positive result

Calcium <8.5 mg/dL, ionized or corrected calcium low, albumin normal or slightly low

II ionized calcium not available, correct calcium for albumin: calcium concentration falls by 0.8 mg/dL, every 1 g/dL fall in albumin.

Magnesium low

Phosphorus low

PTH high

PTH low

Hypoparathyroidism

Abnormalities of vitamin D metabolism

Hyperparathyroidism

Hypocalcemia

Hypomagnesemia

Rickets

Vitamin D deficiency

Cirrhosis

Nephrotic syndrome

Malnutrition

Burns

Chronic illness

Sepsis

Timothy J. Coker, MD, FAAFP
HYPOGLYCEMIA

Aimee Dawson, PharmD and Stephanie J. Billings, MD

HYPOKALEMIA

Differential diagnosis

GI losses
- Vomiting
- Diarrhea
- Nasogastric tube
- Laxative abuse
- Fatass
- Villous adenoma
- Ureterosigmoidostomy
- Malabsorption
- Radiation enteritis

Renal losses
- Medications: diuretics (especially loop and thiazide), amphotericin B, anthracyclines
- Acute kidney injury
- Chronic kidney disease
- Nephrotic syndrome
- Nephrogenic diabetes insipidus
- Bartter syndrome
- Liddle syndrome
- Vasculitis
- Hypomagnesemia

Poor dietary intake
- Alcoholism
- Too fast and lost diet
- Anorexia nervosa

Intracellular shifts
- Metabolic alkalosis
- Insulin excess
- Aldosterone excess (primary or secondary)
- Hypokalemic periodic paralysis
- Interstitial edema (theophylline, caffeine, barium, tolbutamide)
- Hypothermia

Osmotic diuretics (e.g., poorly controlled diabetes)

Renal tubular acidosis (types I and II)

Treatment of hypokalemia

Mild to moderate (usually asymptomatic)
- K 2.5–3.4 meq/L
- PO replacement:
  - HCI 40–120 meq in divided doses
  - IV replacement only when PO repletion contraindicated

Severe (or symptomatic)
- K <3.5 meq/L
- IV replacement:
  - Peripheral line:
    - 0 up to 20 meq/h
  - Central line (for concentrations >20 meq/L)

Increased loss in sweat
- Dialysis (plasmapheresis)

Abirami Raveendran, MD, MSc and Kimberly Bombaci, MD
HYPONATREMIA

Anne Walsh, ANP-BC and Konstantinos E. Deligiannidis, MD, MPH, FAAFP

HYPOTENSION

Organ hypoperfusion, altered mental status, tachycardia, diaphoresis, with or without hypotension

- Altered mental status
- Hypotension
- Tachycardia
- Diaphoresis

No

History of potential volume loss (vasoconstriction, hemorrhage, burns, interstitial fluid, severe diarrhea, etc., ECG, D & C, dehydration, excessive fluid loss, etc.)

- Young, healthy, normotensive
- No history of volume loss

Yes

Is the patient stable?

- Yes

- No

- Seizures
- Hypotension
- Cardiac arrest

Yes

- Autonomic dysfunction/irritability
- Diuretics
- Diabetic ketoacidosis
- Severe anemia
- Chronic renal failure
- High fever

No

- Shock
- Hypotension
- Cardiac arrest

Yes

- Septic shock
- Anaphylactic shock
- Neurogenic shock
- Hypovolemic shock
- Cardiogenic shock
- Obstructive shock

Septic shock

Consider sources of bacteraemia based on clinical symptoms and potential infectious aetiologies.

Anaphylactic shock

Suspect anaphylaxis (food, insect stings, drugs, latex) Tachycardia, hypotension, rash, oedema

Neurogenic shock

Brain injury, shock, hypovolaemia, hypotension, hypoxia, hypothermia

Hypovolemic shock

Dysfunction of the metabolic pathways, hypovolaemia, hypotension, acidosis

Cardiogenic shock

Severe cardiac dysfunction, shock, hypotension, tachycardia, hypotension

Obstructive shock

Severe pulmonary hypertension, shock, hypotension, tachycardia, hypotension

- Treatment of blood pressure
- Fluid resuscitation
- Vasopressor therapy
- Inotropic therapy
- Cardiac monitoring
- Intensive care monitoring
- Surgical intervention
- Dialysis
- Hemodialysis
- Nrenal replacement therapy

Sara Bounader, MD and Sandra S. Augusto, MD, MPH
Frank J. Domino, MD
KNEE PAIN

Julie A. Creech, DO, Michael McNeely, MD, and Stephanie Fulleborn, MD

Curtis L. Galke, DO

LOW BACK PAIN, CHRONIC

Common causes: radiculitis, SI joint dysfunction, trauma, trochanteric bursitis, piriformis syndrome, osteoporosis, osteoarthritis, paravertebral fracture, myelospongiosis, myositis ossificans, malignancy, varicella zoster virus (postherpetic neuralgia), abdominal aortic aneurysm

Pain >3 months

Abnormal gait, bowel/bladder incontinence, acute urinary retention, bilateral sciatica, IV drug abuse, history of malignancy, pain worse when supine, saddle anesthesia, progressive neurologic symptoms, recent injection

Yes

No

Fever or concern of infection?

Yes

No

Urinalysis or MRI

Yes

No

Nonradiological: intradiscal injection

Nonradiological, selective nerve root injection

MRI or CT scan

Yes

No

Neurological referral

Positive

Negative

Plain x ray

Yes

No

Nonpharmacotherapy: structured exercise, multidisciplinary rehab, weight loss, acupuncture, spinal manipulation therapy, progressive relaxation, cognitive-behavioral therapy

Pharmacotherapy: NSAIDs, skeletal muscle relaxants (i.e., lidocaine, cyclobenzaprine), antidepressants (i.e., duloxetine), anticonvulsants (i.e., topiramate), Botox, tramadol

Nonradiological: intradiscal injection

Pharmacotherapy: NSAIDs, skeletal muscle relaxants (i.e., lidocaine, cyclobenzaprine), antidepressants (i.e., duloxetine), anticonvulsants (i.e., topiramate), Botox, tramadol, other options

*Use with caution

No improvement: consider surgical or psychosocial referral

Kiet T. La, MD and Holly L. Baab, MD
LYMPHADENOPATHY

LYMPHOPENIA OR LYMPHOCYTOPENIA

WBC <4,500/µL

- Isolated neutropenia
  - ANC <1,500/µL
    - Evaluate for neutropenia.
- Isolated lymphopenia
  - ALC <1,500/µL
    - Common causes
      - Infections (including HIV, influenza, tuberculosis)
      - Medications (especially prednisone and other immunosuppressives)
      - Nonpathological lymphopenia (especially in the elderly)
    - Risk factors for infection
      - Consider workup for the following:
        - HIV
        - Influenza
        - Hepatitis
        - Tuberculosis
        - Malaria
        - Histoplasmosis
    - Healthy elderly patient
      - In the absence of infection, weight loss, or other concerning history, no further investigation is necessary.
- Concomitant anemia and/or thrombocytopenia
  - Evaluate for causes of pancytopenia.

History of suspicious medications
- Immunosuppressives
  - Prednisone, MTX, azathioprine, etc.
  - Monoclonal antibody therapy
  - Rituximab
  - Chemotherapy

Other
- Malnutrition
- Alcohol abuse
- Signs of underlying lymphoma or other malignancy
- Weight loss, fever, night sweats
- Immuno-mediated disease
- RA, SLE, sarcoidosis, IBD
- Systemic, chronic disorders
  - CKD, CHF

Andrew Smith, MD and Erin Bassett-Novoa, MD
PULPITATIONS, ADULT

Common causes: cardiac arrhythmia, medications, psychiatric issues (anxiety, panic), anemia, thyroid disease

History, physical, 12-lead ECG

Abnormal ECG, clinical history, family history of premature CHD, or physical exam

See “Cardiac Arrhythmias” algorithm: Consider cardiology referral

Normal ECG, physical exam

Cardiac risk factors, age >50 years, DM, tobacco abuse, hyperlipidemia, or symptoms associated with syncope or near syncope?

Yes

Holter monitor or cardiology referral

No

Medications?

Yes

Persistent, distressing symptoms despite treatment

Signs of psychiatric illness? (DSM-IV criteria)

Yes

No

Beta-blocker, alcohol, narcotic, benzodiazepine

Panic disorder, anxiety disorder, somatization, depression

Check labs: CBC, TSH, chemistries

Anemia

Hypothyroidism

Hypoglycemia

No

Caffeine, alcohol, cocaine, nicotine, decongestants

Withdrawal symptoms?

No

Recurrent palpitations after discontinuing potential causative medications

Normal labs, recurrent palpitations

Frank J. Domino, MD

  - Functional disorder
  - Domestic violence
  - History sexual abuse/incest

Frank J. Domino, MD
Ashley Twyman, MD and Clayton Smith, MD, FACP
Nicole Shields, MD

PREOPERATIVE EVALUATION OF NONCARDIAC SURGICAL PATIENT

1. Patient scheduled for surgery with risk factors for coronary artery disease or known as CAD
   - No: Proceed to surgery.
   - Yes: Assess functional capacity: Is patient able to climb two flights of stairs without significant shortness of breath?
     - Yes: Proceed to surgery.
     - No or unknown: Assess risk of major adverse coronary events (MACE) per risk calculator at www.surgicalriskcalculator.com.
       *Age, creatinine, ASA classification, functional living status, type of procedure
       - If MACE <1%: Proceed to surgery.
       - If MACE >1% and further testing will impact decision making: Pharmacologic stress testing is indicated.

Andrew E. Grimes, MD and Stacy L. Jones, MD, FASA
PROTEINURIA

PULMONARY EMBOLISM, DIAGNOSIS

Lawrence M. Gibbs, MD, MSEd, FAAFP

PULMONARY EMBOLISM, TREATMENT

- Consider fondaparinux or argatroban (caution use of argatroban in liver disease) and vitamin K antagonist (warfarin) with at least 3 days of concomitant therapy. When used in combination, goal INR prior to discontinuation of the parenteral product is as follows: INR >2 (tinzaparin) or >3 (argatroban) x 24 hours. If not, argatroban falsely elevates the INR which could be misleading when given in combination with vitamin K antagonist. Once the INR is >4, discontinue the argatroban and recheck the INR in 6–8 hours with a goal INR of 2–3.
- Alternatively, consider using a new oral anticoagulant such as edoxaban or rivaroxaban without need for parenteral bridging (rifampin, disopyramide and omeprazole require 5–10 days of parenteral therapy).
- Prior to using vitamin K antagonist (warfarin) for new onset heparin-induced thrombocytopenia, be sure platelets are >150,000.

Begin either:
- Heparin infusion to therapeutic aPTT, therapeutic dose low-molecular-weight heparin (LMWH), and warfarin
- Discontinuing LMWH when INR >2 for at least 24 hours and minimum 5 days of concomitant therapy; goal INR 2–3
- New oral anticoagulant such as edoxaban or rivaroxaban without need for parenteral bridging (rifampin, disopyramide and omeprazole require 5–10 days of parenteral therapy). Stable low-risk patients may be treated as outpatients with an appropriate regimen above.

Rectal bleeding and hematocchezia

Common causes:
- Hemorrhoids (int/ext)
- Diverticulosis
- Colitis (IBD, infectious)
- Rectal fissure
- Colorectal cancer
- Angiodysplasia

Labs:
- CBC, BMP,
- PT/PTT/INR,
- type and cross

Hemodynamically stable?

- Yes
  - Age <40 years and no anemia?
  - Yes
    - External exam and DRE
  - No
    - External hemorrhoids or fissure?
    - Yes
      - Anoscopy to evaluate for internal hemorrhoids
      - Treat conservatively.
    - No
      - Colonoscopy and upper endoscopy
      - If negative, consider TC-RBC scan and/or angiography

- No
  - Colonoscopy
  - If negative, upper endoscopy
  - If negative, video capsule endoscopy

Sirmad B. Chaudhary, MD and Kristine J. Krueger, MD
RED EYE

Most common causes: conjunctivitis, epidermophytis, otitis, subconjunctival hemorrhage, uveitis, acute angle closure glaucoma, keratitis, corneal abrasion

Pain?

Yes

Decreased vision?

Yes

Keratitis* (Associated photophobia, blurry vision and light discharge possible)

Prescribe topical antibiotics, avoid patching

No

Corneal abrasion (Positive fluorescein staining, deep, foreign body sensation)

Yes

Mucopurulent

Watery

Subconjunctival hemorrhage

Don't presure

No

Scleritis* (Photophobia, no blurry vision, no discharge or foreign body sensation)

Prescribe warm compresses and topical antibiotic

No

Evaluate pupillary reaction

Constricted Glaucom

Nonreactive

Uveitis* (Associated photophobia with pain, erythema of vessels to corneas, no limbal reaction)

Acute angle closure glaucoma* (Associated photophobia, nausea)

Allergic conjunctivitis (Associated itch)

Prescribe antihistamines topically and/or oral

Viral conjunctivitis

Reassurance, careful hand washing

Epidermophytis

Reassurance, expect resolution in a few days

*Urgent ophthalmology consultation

Efstathia Choros, MD, CPA and Paul E. Daniel Jr., MD
SUICIDE, EVALUATING RISK FOR

Screen all depressed patients annually (and additional testing if depression or recent loss of access to long-term opiates or benzodiazepine use).

Over the past 2 weeks, how often have you been bothered by:
1) Little interest or pleasure in doing things?
2) Feeling down, depressed, or hopeless?

Score each of the 2 questions on a scale of 0–3 (0 ["not at all"] to 3 ["nearly every day"]).

Score <3: negative depression screen
Score ≥3: positive depression screen

Ask about suicidal ideation (if +, ask about a plan):
- "Have you ever felt that life isn’t worth living?"
- "Did you ever wish you could go to sleep and not wake up?"
- "Are you having thoughts about hurting yourself or others?"

If any + (or if negative and you suspect patient is not being honest or is incompetent), get further expert advice.

Higher risk
- Question for mood instability (worsening anxiety)
- Losses (support)
- Detracting events (injury, substance abuse, etc.)
- Personal/family history of suicide attempts
- Neurologic/psychiatric comorbidities

Lower risk
- Close clinical follow-up

Preoccupation with suicide is a medical emergency, and measures should be taken immediately to keep the patient safe. This includes putting the patient under constant 1:1 supervision and inpatient admission and consultation.

Nupam A. Patel, MD and Samuel B. Carli, MD

Tinnitus

Shannon Roche, DO and Sara Casey, DO

TRANSIENT ISCHEMIC ATTACK AND TRANSIENT NEUROLOGIC DEFECTS

TIA defined as a “transient episode of neurologic dysfunction caused by focal cerebral spinal cord or retinal ischemia without acute infarction” (AHA/ASA, 2000)

Common causes: migraine (v/- aura), carotid artery disease, stroke, seizure, syncope, subarachnoid hemorrhage, multiple sclerosis, ALS

Clinical suspicion of a TIA: episode of neurologic deficit, unilateral paresis, memory loss, headache, blurred vision, dysarthria, hemianopia, or diplopia

Risk factors: cigarette smoking, obesity, diabetes mellitus, dyslipidemia, hypertension, family history of coagulation disorder, or recent TIA

Emergent evaluation:
- ECG
- Echoangiogram
- Blood glucose
- Serum electrolytes
- Lipids

Symptoms resolved?

CT or MRI evidence of stroke?

CT or MRI evidence of stroke?

Stroke protocol

Differential diagnosis of TIA:
- brain tumor, CNS infection, trauma, hypoglycemia, migraines, multiple sclerosis, seizure disorder, and vertigo

Workup:
- MRI within 24 hours
- Carotid studies
- Consider ABCD² score for admission

ABCD² score
- (age, blood pressure, clinical presentation, diabetes mellitus, duration of symptoms)
- Age > 60 years 1 pt
- SBP > 140 mm Hg 1 pt
- OR
- DBP > 90 mm Hg 1 pt
- Unilateral weakness 2 pts
- Speech impairment 1 pt
- Diabetes mellitus 1 pt
- Duration of TIA > 60 minutes 2 pts
- 10-59 minutes 1 pt

Admit patients with an ABCD² score > 3 who present within 72 hours of symptom resolution, evidence of focal ischemia, or cannot complete outpatient workup.

Deborah A. Lardner, DO, DTM&H and Michael Passafaro, DO, DTM&H, FACEP, FACOEP

TREMOR

Common causes: essential tremor, physiologic tremor, Parkinson disease, parkinsonian syndrome, medication, alcoholism, drug withdrawal, Fragile X mental typically

Taking:
- Amiodarone
- Tricyclic antidepressants
- Amphetamine
- Topical anesthetics
- β Blockers
- Propoxyphene
- GABA agonists
- Antihypertensives
- Benzodiazepine
- Pregabalin
- Thyroid replacement
- Tyrosine
- Valproic acid

Check TSH, BUN, creatinine, RPR, vitamin B12, and electrolytes.

Abnormal
- Treat accordingly

Normal

Mo

Wear off as needed and check serum drug level if indicated

Tremor at rest (limb supported against gravity)
- Bradykinesia, rigidity, postural instability
  - Parkinson disease
  - Parkinsonian syndrome
  - Severe essential tremor
  - Trial of propylenol (in case of essential tremor), trial dopaminergic agents

Postural tremor (limb maintained against gravity)
- Alcohol withdrawal
- Panic disorder
- Anxiety
- Benzodiazepine withdrawal
- Essential tremor
- Handwriting tremor
- Peripheral neuropathy

Isometric tremor (tremor with muscle contraction against stationary object)
- For peripheral neuropathy, trial gabapentin
- For essential tremor, trial β blockers, Felbinac, trihexyphenidyl, or 2nd generation antipsychotics

Kinetic tremor (tremor with voluntary movement)
- Large extremity movement
- Simple kinetic tremor
- Intention tremor: cerebellar lesion (CVA, MS)

Psychogenic tremor (tremor relieved by distraction)
- Stress reduction

Steven J. Crosby, MA, BSP, RPh, FASCP and Ildiko Halasz, MD
TYPE 2 DIABETES, TREATMENT

FIRST LINE therapy is metformin and comprehensive lifestyle changes (including weight management and physical activity).

- If HbA1c remains above goal, proceed below.

- If initial HbA1c is >8.5% or 1.5% above A1c target, can consider initiation of dual therapy (metformin + second agent)
- If initial HbA1c is <8.5% or 1.5% below A1c target, can consider starting triple combination (GLP-1 RA and/or basal insulin therapy)

Without known or established ASCVD, HFREF or CKD, choose primary deciding factor below for initiation of second agent

**To minimize risk of hypoglycemia**
- GLP-1 RA, SGLT2i, TZD, or DPP-4i

**To promote weight loss or limit weight gain**
- GLP-1 RA with good efficacy for weight loss or SGLT2i

**If HbA1c remains above target**
- Consider adding the other class (GLP-1 RA or SGLT2i)
- DPP-4i if not on GLP-1 RA
- Basal Insulin

**Addition of other agent above**
- AVOID use of DPP-4i and GLP-1 RA together

- **Addition of other agent above**
- Avoid use of DPP-4i and GLP-1 RA together

- **Addition of other agent above**
- Avoid use of DPP-4i and GLP-1 RA together

- **Addition of other agent above**
- Avoid use of DPP-4i and GLP-1 RA together

**If HbA1c remains above goal despite 3 months of triple therapy:**
1. If on oral combination, consider move to GLP-1 RA before basal insulin unless HbA1c >11%, or significant symptoms of insulin insufficiency
2. If on GLP-1 RA, add basal insulin
3. If on optimally titrated basal insulin, add GLP-1 RA or mealtime insulin

**HFREF**: Heart Failure reduced Ejection Fraction

**GLP-1 RA**: with CV benefit: lixisenatide, exenatide, dulaglutide; with greatest weight loss benefit: semaglutide, lixisenatide, and dulaglutide

**SGLT2i**: with CV benefit: empagliflozin and canagliflozin; dapagliflozin is CV risk neutral but may reduce HF hospitalizations (Do not use SGLT2i if LVEF <40)

**DPP-4i**: saxagliptin, sitagliptin, or exenatide; saxagliptin associated with increased risk of heart failure admissions

**TZD**: pioglitazone

**SU**: glimepiride, glyburide or glipizide

**Basal Insulin**: insulin detemir, insulin glargine, or insulin glulisine. Start at bedtime or AM at 10 U SC or 0.1-0.2 U/kg/day. Increase by 0.1-0.2 U/kg/day weekly testing B12 at goal or basal dose ≤0.1 U/kg/day

Stephen Carek, MD
VAGINAL BLEEDING, ABNORMAL

Common causes: PCOS, hypothryroid, uterine hyperplasia, polyps, breast cancer.

History and physical exam, including pelvic exam

Prepubescent

Consider CBC, pelvic US, genital cultures, tumor markers, and child abuse referral.

Reproductive age

Pap test, RCG: consider genital cultures, CBC, PT/INR, von Willebrand (VWF) antigen, histocytosis, tuberculosis, vasa scoring.

Postmenopausal

Pap test, US, and/or EMR: consider TSH, prolactin, and genital cultures.

Not pregnant, tests normal

Ovulatory dysfunction for >3 months

Adult

Age >45 years?

No

Pelvic US, TSH, Prolactin; if age >44 years, obtain endometrial biopsy.

Yes

Refer/treat for anovulation: Progesterone.

Normal results

Obtain coagulation evaluation: CBC, peripheral smear, PT/INR, PTT, VWF antigen, histocytosis, factor VIII.

Abnormal results

Treat or refer.

Results normal, age <45 years and without risk for hyperplasia.

Normal results, age >45 years or high risk for hyperplasia

Endometrial biopsy and/or pelvic US

Persistent abnormal bleeding despite treatment?

Normal results

Abnormal results

Treatment, refer.

Abnormal results

Reassurance, treat with hormones.

<3 years from menarche

Reassurance, combination contraceptive

ABNORMAL (DYSFUNCTIONAL) UTERINE BLEEDING
Rebecca Lauters, MD

BASICS

DESCRIPTION
- Abnormal uterine bleeding (AUB) is irregular menstrual bleeding (usually heavy, prolonged, or frequent); it is a diagnosis of exclusion after establishment of normal anatomy and the absence of other medical illnesses and pregnancy.
- May be acute or chronic (occurring >6 months)
- The International Federation of Gynecology and Obstetrics (FIGO) revised the terminology system and now uses AUB rather than dysfunctional uterine bleeding (DUB).
- Commonly associated with anovulation

EPIDEMIOLOGY
Adolescent and perimenopausal women are affected most often.

Incidence
5% of reproductive-aged women will see a doctor in any given year for AUB.

Prevalence
10–30% of reproductive-aged women have AUB.

ETIOLOGY AND PATHOPHYSIOLOGY
- Anovulation accounts for 90% of AUB.
  - Loss of cyclic endometrial stimulation
  - Elevated estrogen levels stimulate endometrial growth.
  - No organized progesterone withdrawal bleeding
  - Endometrium eventually outgrows blood supply, breaks down, and sloughs from uterus.
  - 6–10% will have polycystic ovarian syndrome (PCOS).
- Adolescent AUB is usually due to an immature hypothalamic-pituitary-ovarian (HPO) axis that leads to anovulatory cycles.
- The mnemonic PALM-COEIN was developed to describe AUB in reproductive-aged women.
  - PALM: polyp, adenomyosis, leiomyoma, and malignancy and/or hyperplasia
  - COEIN: coagulopathy, ovulatory disorders, endometrial, iatrogenic, and not yet classified
  - Reproductive pathology and structural disorders
    - Uterus: leiomyomas, endometritis, hyperplasia, polyps, trauma
    - Adnexa: salpingitis, functional ovarian cysts
    - Cervix: cervicitis, polyps, sexually transmitted infections (STIs), trauma
    - Vagina: trauma, foreign body
    - Vulva: lichen sclerosus, STIs
- Malignancy of the vagina, cervix, uterus, and ovaries
- Systemic diseases
  - Hematologic disorders (e.g., von Willebrand disease, thrombocytopenia)
• Diseases causing anovulation
  – Hyperthyroidism/hypothyroidism
  – Adrenal disorders
  – Pituitary disease (prolactinoma)
  – PCOS
  – Eating disorders
• Medications (iatrogenic causes)
  – Anticoagulants
  – Steroids
  – Tamoxifen (estrogen receptor antagonists)
  – Hormonal medications: intrauterine devices (IUDs)
  – Selective serotonin reuptake inhibitors (SSRIs)
  – Antipsychotic medications
  – Postmenopausal hormone therapy
• Other causes of AUB not defined in PALM-COEIN
  – Pregnancy: ectopic pregnancy, threatened or incomplete abortion, or hydatidiform mole
  – Advanced or fulminant liver disease
  – Chronic renal disease
  – Inflammatory bowel disease
  – Excessive weight gain
  – Increased exercise

Genetics
Unclear but can include inherited disorders of hemostasis

RISK FACTORS
Risk factors for endometrial cancer (which can cause AUB)
• Age >40 years
• Obesity
• PCOS
• Diabetes mellitus
• Nulliparity
• Early menarche or late menopause (>55 years of age)
• Hypertension
• Chronic anovulation or infertility
• Unopposed estrogen therapy
• History of breast cancer or endometrial hyperplasia
• Tamoxifen use
• Family history: gynecologic, breast, or colon cancer
• Thyroid disease

DIAGNOSIS

HISTORY
• Menstrual history
  – Onset, severity (quantified by pad/tampon use, presence and size of clots), timing of
bleeding (unpredictable or episodic)

- Menorrhagia with onset of menarche is suggestive of a coagulation disorder.
- Menopausal status
- Association with other factors (e.g., coitus, contraception, weight loss/gain)

- Gynecologic history: gravidity and parity, STI history, previous Pap smear results
- Review of systems (Exclude symptoms of pregnancy and of bleeding disorders, stress, exercise, recent weight change, visual changes, headaches, galactorrhea.)
- Medication history: Evaluate for use of aspirin, anticoagulants, hormones, and herbal supplements (1,2).

**ALERT**

Postmenopausal bleeding is any bleeding that occurs >1 year after the last menstrual period; cancer must always be ruled out (2)[C].

**PHYSICAL EXAM**

Discover anatomic or organic causes of AUB.

- Evaluate for:
  - Body mass index (obesity)
  - Pallor, vital signs (anemia)
  - Visual field defects (pituitary lesion)
  - Hirsutism or acne (hyperandrogenism)
  - Goiter (thyroid dysfunction)
  - Galactorrhea (hyperprolactinemia)
  - Purpura, ecchymosis (bleeding disorders)

- Pelvic exam
  - Evaluate for uterine irregularities and Tanner stage.
  - Check for foreign bodies.
  - Rule out rectal or urinary tract bleeding.
  - Include Pap smear and tests for STIs (2)[C].
  - Consider testing for vaginitis and other local infections (potassium hydroxide, wet prep, aerobic/anaerobic culture)

**Pediatric Considerations**

Premenarchal children with vaginal bleeding should be evaluated for foreign bodies, physical/sexual abuse, possible infections, and signs of precocious puberty.

**DIFFERENTIAL DIAGNOSIS**

See “Etiology and Pathophysiology.”

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Everyone: urine human chorionic gonadotropin (hCG; rule out pregnancy and/or hydatidiform mole) and complete blood count (CBC) (1)
  - For acute bleeding, a type and cross should be obtained (3)[C].
- If disorder of hemostasis is suspected, a partial thromboplastin time (PTT), prothrombin time (PT), activated partial thromboplastin time (aPTT), and fibrinogen level are appropriate (3)[C].
- If anovulation is suspected: thyroid-stimulating hormone (TSH) level, prolactin level (1)
- Consider other tests based on differential diagnosis.
- Follicle-stimulating hormone (FSH) level to evaluate for hypo- or hypergonadotropism
- 17-Hydroxyprogesterone if congenital adrenal hyperplasia is suspected
- Testosterone and/or dehydroepiandrosterone sulfate (DHEA-S) if PCOS
- Screening for STI

Endometrial biopsy (EMB) should be performed as part of the initial evaluation for postmenopausal uterine bleeding and in premenopausal women with risk factors for endometrial carcinoma. Medical management can be initiated in premenopausal women with low risk for malignancy (1)[A].

Transvaginal ultrasound (TVUS) in postmenopausal AUB
- Postmenopausal endometrial thickness (ET) <4 mm does not require endometrial sampling unless bleeding is persistent or recurrent, whereas ET >4 mm should prompt further evaluation.
- ET <3 mm: 99.7% negative predictive value (NPV)
- ET <5 mm: 99.6% NPV for ruling out endometrial cancer (4)
- Incidentally found endometrial measurement >4 mm without associated bleeding in postmenopausal women should not trigger evaluation; however, assessment based on individual risk factors is appropriate.

TVUS, sonohysterography, and hysteroscopy may be similarly effective in detection of intrauterine pathology in premenopausal women with AUB (1)[A].

If normal findings following imaging in patients without known risk factors for endometrial carcinoma, a biopsy should be performed if not done so previously (2)[C].

**Diagnostic Procedures/Other**
- Pap smear to screen for cervical cancer if age ≥21 years (2)[C]
- EMB should be performed in
  - Women age >35 years with AUB to rule out cancer or premalignancy
  - Postmenopausal women with ET ≥4 mm
  - Women aged 18 to 35 years with AUB and risk factors for endometrial cancer (see “Risk Factors”)
  - Perform on or after day 18 of cycle, if known; secretory endometrium confirms ovulation occurred.
- Dilation and curettage (D&C)
  - Perform if bleeding is heavy, uncontrolled, or if emergent medical management has failed.
  - Perform if unable to perform EMB in office (2)[C].
- Hysteroscopy if another intrauterine lesion is suspected

**Test Interpretation**

Pap smear could reveal carcinoma or inflammation indicative of cervicitis. Most EMBs show proliferative or dysynchronous endometrium (suggesting anovulation) but can show simple or complex hyperplasia without atypia, hyperplasia with atypia, or endometrial adenocarcinoma.

**TREATMENT**

Attempt to rule out other causes of bleeding prior to instituting therapy.

**GENERAL MEASURES**

Nonsteroidal anti-inflammatory drugs (NSAIDs) (naproxen sodium 500 mg BID, mefenamic
acid 500 mg TID, ibuprofen 600 to 1,200 mg/day) (1)[B]
- Decreases amount of blood loss and pain compared with placebo, with no one NSAID clearly superior

MEDICATION

First Line
- Acute, emergent, nonovulatory bleeding
  - Conjugated equine estrogen (Premarin): 25 mg IV q4h (max 6 doses) or 2.5 mg PO q6h should control bleeding in 12 to 24 hours (5)[A].
  - D&C if no response after 2 to 4 doses of Premarin or sooner if bleeding >1 pad per hour (2)[C]
  - Then change to oral contraceptive pill (OCP) or progestin for cycle regulation (6)[A]
- Acute, nonemergent, nonovulatory bleeding
  - Combination OCP with ≥30 μg estrogen given as a taper. An example of a tapered dose: 4 pills per day for 4 days; 3 pills per day for 3 days; 2 pills per day for 2 days, daily for 3 weeks then 1 week off, then cycle on OCP for at least 3 months
- Nonacute, nonovulatory bleeding (ranked in order based on decision analysis as best option based on efficacy, cost, side effects, and consumer acceptability) (6)[A]
  - Levonorgestrel IUD (Mirena) is the most effective form of progesterone delivery and is not inferior to surgical management.
  - Progestins: medroxyprogesterone acetate (Provera) 10 mg/day for 5 to 10 days each month. Daily progesterone for 21 days per cycle results in significantly less blood loss.
  - OCPs: 20 to 35 μg estrogen plus progesterone
- Do not use estrogen if contraindications, such as suspicion for endometrial hyperplasia or carcinoma, history of deep vein thrombosis (DVT), migraine with aura, or the presence of smoking in women >35 years of age (relative contraindication), are present.
- Precautions
  - Failed medical treatment requires further workup.
  - Consider DVT prophylaxis when treating with high-dose estrogens (2)[C].

Second Line
- Leuprolide (varying doses and duration of action); gonadotropin-releasing hormone (GnRH) agonist
- Danazol (200 to 400 mg/day for a maximum of 9 months) more effective than NSAIDs but limited by androgenic side effects and cost. It has been replaced by GnRH agonists.
- Antifibrinolytics such as tranexamic acid (Lysteda) 650 mg, 2 tablets TID (max 5 days during menstruation) (1)[A]
- Metformin or clomifene (Clomid) alone or in combination in women with PCOS who desire ovulation and pregnancy

ISSUES FOR REFERRAL
- If an obvious cause for vaginal bleeding is not found in a pediatric patient, refer to a pediatric endocrinologist or gynecologist.
- Patients with persistent bleeding despite medical treatment require reevaluation and possible referral.

ADDITIONAL THERAPIES
- Antiemetics if treating with high-dose estrogen or progesterone (2)[C]
- Iron supplementation with vitamin C if anemia (usually iron deficiency) is identified
- Ulipristal acetate 5 mg or 10 mg (selective progesterone receptor modulator) currently under investigation for use in women with leiomyoma-associated AUB

**SURGERY/OTHER PROCEDURES**
- Hysterectomy in cases of endometrial cancer or if medical therapy fails or if other uterine pathology is found
- Endometrial ablation, less expensive than hysterectomy and associated with high patient satisfaction; failure of primary medical treatment is not necessary (1,5)[A].
  - This is a permanent procedure and should be avoided in patients who desire continued fertility.
- Uterine artery embolization if bleeding is refractory to medications or confirmed fibroids

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Significant hemorrhage causing acute anemia with signs of hemodynamic instability; with acute bleeding, replace volume with crystalloid and blood, as necessary (1)[A].
- Pad counts and clot size can be helpful to determine and monitor amount of bleeding.
- Discharge criteria
  - Hemodynamic stability
  - Control of vaginal bleeding (2)[C]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Once stable from acute management, recommend follow-up evaluation in 4 to 6 months for further evaluation (6).
- Routine follow-up with a primary care or OB/GYN provider

**Patient Monitoring**
Women treated with estrogen or OCPs should keep a menstrual diary to document bleeding patterns and their relation to therapy.

**DIET**
No restrictions, although a 5% reduction in weight can induce ovulation in anovulation caused by PCOS

**PATIENT EDUCATION**
Explain possible/likely etiologies.
- Answer all questions, especially those related to cancer and fertility.
- [https://www.acog.org/Patients](https://www.acog.org/Patients)
- [https://www.uptodate.com](https://www.uptodate.com) (patient education)

**PROGNOSIS**
- Varies with pathophysiologic process
- Most anovulatory cycles can be treated with medical therapy and do not require surgical intervention.
COMPLICATIONS

- Iron deficiency anemia
- Uterine cancer in cases of prolonged unopposed estrogen stimulation

REFERENCES

ADDITIONAL READING

SEE ALSO

- Dysmenorrhea; Menorrhagia (Heavy Menstrual Bleeding)
- Algorithm: Abnormal Uterine Bleeding

CODES

ICD10

- N93.9 Abnormal uterine and vaginal bleeding, unspecified
- N93.8 Other specified abnormal uterine and vaginal bleeding
- N91.2 Amenorrhea, unspecified

**CLINICAL PEARLS**

- AUB is irregular bleeding that occurs in the absence of pregnancy or pathology, making it a diagnosis of exclusion.
- Anovulation accounts for 90% of AUB.
- An EMB should be performed in all women >35 years of age with AUB to rule out cancer or premalignancy, and it should be considered in women aged 18 to 35 years with AUB and risk factors for endometrial cancer.
- It is appropriate to initiate medical therapy in females <35 years of age with no apparent risk of endometrial cancer prior to performing an EMB.
BASICS

DESCRIPTION
- Cervical dysplasia: premalignant cervical disease that is also called cervical intraepithelial neoplasia (CIN); precancerous epithelial changes in the transformation zone of the uterine cervix almost always associated with human papillomavirus (HPV) infections
- CIN encompasses a range of histologic diagnoses.
  - CIN I: mild dysplasia; low-grade lesion; cellular changes are limited to the lower 1/3 of the squamous epithelium.
  - CIN II: moderate dysplasia; high-grade lesion; cellular changes are limited to the lower 2/3 of the squamous epithelium.
  - CIN III or carcinoma in situ: severe dysplasia; high-grade lesion; cellular changes involve the full thickness of the squamous epithelium.
- System(s) affected: reproductive

Pediatric Considerations
Only 0.1% of cervical cancers occur before age 20 years. Screening women age <21 years (regardless of sexual history) does not reduce cervical cancer incidence and mortality compared with beginning screening at age 21 years. Screenings of adolescents lead to unnecessary evaluation and overtreatment of cervical lesions, which are highly likely to spontaneously regress.

Geriatric Considerations
- Women age >65 years who have had adequate prior screening and no history of CIN II+ in the last 20 years should not be screened for cervical cancer. Adequate prior screening is defined as three consecutive, negative cytology results or two consecutive, negative HPV-positive cytology “contesting” results within 10 years before cessation of screening (with the most recent test within the last 5 years).
- Routine screening should continue for at least 20 years after spontaneous regression or appropriate management of a high-grade precancerous lesion, even if this extends screening past the age 65 years.

Pregnancy Considerations
- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- Colposcopy only to exclude the presence of invasive cancer in high-risk women
- Endocervical curettage is contraindicated during pregnancy.
- Unless cancer is identified or suspected, treatment of CIN is contraindicated during pregnancy.

EPIDEMIOLOGY
Cervical cancer is the fourth most common type of cancer in women worldwide. It is the second leading cause of cancer death in women aged 20 to 39 years (1). However, in the United States, due to improved screening practices, cervical cancer has dropped to 14th place in the list of most common cancers. Incidence of CIN III peaks between ages 25 and 29 years; invasive disease
peaks 15 years later. Cervical cancer most commonly occurs in women aged 35 to 44 years. >15% of cervical cancer cases occur in women >65 years of age (occurs in those who did not get regular screening).

Incidence
- In 2019, it was projected that there would be 13,170 new cases of cervical cancer diagnosed and 4,250 women will die from the disease, making it the 18th leading cause of death from cancer in the United States (1).
- The incidence of cervical cancer in the United States has decreased by >50% in the past 40 years because of widespread cervical cancer screening tests (2).

Prevalence
- In 2016, there were an estimated 289,696 women living with cervical cancer in the United States (1).
- In 2013 to 2014, the estimated prevalence of CIN II among 21- to 24-year-olds was 732/100,000 screened women in the United States (2).
- Multiple studies in populations around the world have found that prevalence of high-grade dysplasia has fallen significantly in HPV-immunized populations (3).

ETIOLOGY AND PATHOPHYSIOLOGY
HPV DNA is found in virtually all cervical carcinomas and precursor lesions worldwide. HPV is so common that most sexually active men and women will get at least one type of HPV at some point in their lives.
- High-risk HPV types: 16, 18, 31, 33, 35, 45, 52, and 58 are common oncogenic virus types for cervical cancer.
- HPV 16 and 18 are associated with ~70% of all cervical cancers.
- Most HPV infections are transient, becoming undetectable within 1 to 2 years. Persistent infections are what place women at significant risk for developing precancerous lesions. Compared to younger women, women age >30 years are less likely to clear a new HPV infection.
- Low-risk types: HPV viral types 6, 11, 42, 43, and 44 are considered common low-risk types and may cause genital warts. HPV 6 and 11 (cause 90% of benign anogenital warts) can lead to low-grade squamous intraepithelial lesion (LSIL) and CIN I.

RISK FACTORS
- Previous or current HPV infection
- HIV infection and other immunosuppressive conditions
- In utero exposure to diethylstilbestrol
- Previous treatment of a high-grade precancerous lesion or cervical cancer
- Cigarette smoking
- Multiple sexual partners
- Some correlation with low socioeconomic status, high parity, oral contraceptive use, and poor nutrition

GENERAL PREVENTION
- Immunization: Immunization decreases high-risk HPV infections and CIN II/III cervical pathology for at least 5 to 7 years but has not yet been shown to decrease cervical cancer. It is likely that prevention of invasive cancer will be demonstrated within a few years.
– Ideally, HPV immunization of girls, boys, and women should be initiated prior to first intercourse. Per the Advisory Committee on Immunization Practices (ACIP), offer HPV vaccine to adolescents 11 to 12 years of age.
– Gardasil 9: The U.S. FDA approved in October 2018 for use in females and males ages 9 to 26 years and for ages 27 to 45 years; 88% effective preventing dysplasia due to HPV types 16 and 18 (75% of cervical cancer), types 6 and 11 (anogenital warts), and protection against five additional HPV types that cause approximately 25% of CIN II+ lesions
– Vaccine schedule: if vaccine begun before 15th birthday: 2 doses only 6 to 12 months apart
  – If vaccine begun on or after 15th birthday: 3 doses at 0, 2, and 6 months
– Immunocompromising conditions: 3 doses needed
  – Safe sex practices: condom use
  – Screening

### Pap smear
- Pap smear has been the main screening test for cervical cellular pathology, with or without cotesting for HPV. A 2017 draft recommendation on cervical screening from the U.S. Preventive Services Task Force recommends either cytology testing at 3-year intervals or primary HPV testing at 5-year intervals for women 30 to 65 years of age. Clinicians will need to choose whether to adopt an HPV-only approach or a cotesting approach (4)[B].
- Screening recommendations by age and source (see algorithm “Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older” and separate algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years”)
  - <21 years: Do not screen (5)[A] (U.S. Preventive Services Task Force [USPSTF]/American Society for Colposcopy and Cervical Pathology [ASCCP]/American Cancer Society [ACS]/ASCP/American College of Obstetricians and Gynecologists [ACOG]).
  - 21 to 29 years: Screen with cytology (Pap smear) every 3 years (5)[A]. Do not screen with HPV testing alone or combined with cytology (5)[A].
  - 30 to 65 years: Screen with cytology every 3 years (acceptable) or cotesting (cytology/HPV testing) every 5 years (preferred).
  - >65 years (who have had adequate prior screening and are not high risk): Do not screen (5).
  - Special circumstances: women after hysterectomy with removal of the cervix and with no history of CIN II+: Do not screen (5)[A]. Women with history of CIN II+ should continue screening until 20 years following their diagnosis of CIN II+.
  - HIV-positive women: Screen every 3 years in those who have had three consecutive normal annual Pap tests and every 3 years cotesting in women ages 30 years and older.

## DIAGNOSIS

### HISTORY
- Usually asymptomatic until there is invasive disease. Patients may present with vaginal discharge, abnormal vaginal bleeding, postcoital bleeding, pelvic pain, cervical mass, or bladder obstruction.

### PHYSICAL EXAM
Pelvic exam occasionally reveals external HPV lesions. Examine for exophytic or ulcerative cervical lesions, with or without bleeding.

**DIFFERENTIAL DIAGNOSIS**
Acute or chronic cervicitis; cervical glandular hyperplasia; cervical polyp; cervical fibroid; HPV infection; invasive cervical malignancy; uterine malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**
- Current evidence indicates no clinically important differences between conventional cytology and liquid-based cytology in detecting cervical cancer precursors. Conventional Pap smear involves a cervical sample plated on a microscope slide with fixative. ThinPrep is a liquid-based collection and thin-layer preparation.
- To ensure an adequate sample of both the ecto- and endocervix, use a cytobrush and an extended tip spatula.
- The sensitivity and specificity of using HPV and Pap testing together (cotesting) for dysplasia is near 100% and 92.5%, respectively. Cotesting leads to earlier diagnosis of CIN III+ and cancer than does cytology alone, but it is likely that testing for high-risk HPV without cytology will become the dominant strategy, particularly for poorly screened or unscreened populations (2)[A].
- Cytology report component: specimen type (conventional Pap smear or liquid based), adequacy (presence of endocervical cells), and categorization (negative for intraepithelial lesion or malignancy or epithelial cell abnormality; i.e., squamous/glandular)
- Bethesda 2014 system (cytologic grading) epithelial cell abnormalities
  - Squamous cell
    - Atypical squamous cells (ASC) (of undetermined significance [ASC-US], cannot exclude high-grade squamous intraepithelial lesion or HSIL [ASC-H])
    - HPV, mild dysplasia, CIN I
    - Moderate/severe dysplasia CIS, CIN II, and CIN III
  - Glandular cell
    - AGCs (atypical glandular cells)
      - AGCs: not otherwise specified
      - AGCs: favor neoplasia
    - AIS (adenocarcinoma in situ)
    - Adenocarcinoma

**Diagnostic Procedures/Other**
Some algorithms differ for women age 21 to 24 years; see “ASCCP guidelines” (6) and 5MCC algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years”; below recommendations for ages as noted
- HPV positive, cytology negative (30 years of age and older)
  - Option 1: HPV DNA typing: If HPV 16 or 18 positive, proceed to colposcopy; if negative, repeat cotesting at 1 year.
  - Option 2: Repeat cotesting at 1 year: If ASC or HPV positive, proceed to colposcopy; if negative, repeat cotesting at 3 years.
- ASC-US: (>24 years of age)
  - Option 1: HPV testing (preferred)
    - If HPV positive, proceed to colposcopy (6)[B].
If HPV negative, repeat cotesting at 3 years (6)[B].
  - Option 2: Repeat cytology at 1 year (acceptable) (6).
  
- If repeat cytology ASC or greater, proceed to colposcopy.
- If repeat cytology is negative, proceed to routine screening in 3 years.
- ASC-H: colposcopy required
- LSIL: (>24 years of age)
  - LSIL with negative HPV test: Repeat cotesting at 1 year (preferred).
  - If repeat cotesting is negative, repeat cotesting in 3 years.
  - If cotesting is positive, proceed to colposcopy.
  - LSIL with no HPV test or positive HPV test: Proceed to colposcopy.
- LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to postpartum (6)
- HSIL: loop electrosurgical excision procedure (LEEP) or colposcopy
- AGCs: colposcopy with endocervical sampling and endometrial sampling (if 35 years or older or at risk for endometrial neoplasia)
- Atypical endometrial cells: endometrial and endocervical sampling
  - If negative, perform colposcopy.
- Women with no lesion on colposcopy or CIN I (preceded by “lesser abnormalities” such as ASC-US, LSIL, HPV 16+, HPV 18+, and persistent HPV)
  - Follow-up without treatment: cotesting at 12 months
  - If both HPV and cytology are negative, age-appropriate retesting 3 years later
  - If either positive, proceed to colposcopy. If persistent CIN I for at least 2 years, proceed to treatment with ablative or excisional methods.
- Ages 21 to 24 years: Management is slightly different than above; see “ASCCP guidelines” (6) or algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years.”
- Age >30 years: If cytology is negative but HPV is positive, repeat cotesting at 1 year is acceptable.

Test Interpretation
Atypical squamous or columnar cells, coarse nuclear material, increased nuclear diameter, koilocytosis (HPV hallmark)

TREATMENT
ASCCP guidelines: Evidence-based management algorithms guide Pap smear and postcolposcopic diagnostics and therapeutics are available online at http://www.asccp.org/colposcopy-standards (6).

GENERAL MEASURES
Office evaluation and observation; promote smoking cessation; promote protected intercourse; promote immunization.

MEDICATION
- Infective/reactive Pap smear: Treat trichomoniasis, symptomatic Candida, or shift in flora suggestive of bacterial vaginosis found on Pap smear results.
- Condyloma acuminatum treatment options: See chapter “Condylomata Acuminata.”
SURGERY/OTHER PROCEDURES

- Persistent CIN I, II, or III: ablative or excisional methods. If inadequate colposcopy for CIN II or III or recurrent CIN II or III, diagnostic excisional procedure is done. For AIS, hysterectomy is preferred.
- Cryotherapy, laser ablation, LEEP/large loop excision of transition zone, or cold-knife conization are all effective but require different training and with different side effects for patient. If cervical malignancy, see “Cervical Malignancy.”

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

After treatment (excision or ablation) of CIN II or III, women may reenter routine screening only after negative cotesting between 12 and 24 months. Screening should be continued for 20 years.

DIET

Promote increased intake of antioxidant-rich foods.

PATIENT EDUCATION

HPV vaccination, smoking cessation, protected intercourse, regular screening with Pap smear per guidelines

PROGNOSIS

- Progression of CIN to invasive cervical cancer is slow, and the likelihood of regression is high:
  - Up to 43% of CIN II and 32% of CIN III lesions may regress. CIN III has a 30% probability of becoming invasive cancer over a 30-year period, although only about 1% if treated (4).
- CIN III becomes invasive: Lesions discovered early are amenable to treatment with excellent results and few recurrences.
- 1- and 5-year relative survival rates for cervical cancer patients are 87% and 68%, respectively.
  - The 5-year survival rate for patients diagnosed with localized disease is 91% (4).

COMPLICATIONS

Aggressive cervical surgery may be associated with cervical stenosis, cervical incompetence (leading to preterm labor), and scarring affecting cervical dilatation in labor.

SEE ALSO

- Cervical Malignancy; Condylomata Acuminata; Trichomoniasis; Vulvovaginitis, Prepubescent Algorithms: Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older; Pap, Normal and Abnormal in Women Ages 21–24 Years

CODES

ICD10

- R87.619 Unspecified abnormal cytological findings in specimens from cervix uteri
- N87.9 Dysplasia of cervix uteri, unspecified
- N87.1 Moderate cervical dysplasia

CLINICAL PEARLS

- HPV is present in virtually all cervical cancers (99.7%), but most HPV infections are transient.
- Vaccine should be offered prior to onset of any sexual activity for maximum effectiveness but may be offered up to age 45 years (88% protective in women age 27 to 45 years against warts, squamous intraepithelial lesion, and cancer).
- Know and adhere to recognized screening guidelines to avoid the harms of overscreening.
- Optimal screening strategy is in evolution. HPV-only screening is being studied.
ACETAMINOPHEN POISONING
Luis T. Garcia, MD ● Daniella D. Brutman, MD

BASICS

DESCRIPTION
- A disorder characterized by hepatic necrosis following large acetaminophen ingestions. Although patients can be asymptomatic, common presenting symptoms include nausea, vomiting, diaphoresis, malaise, jaundice, confusion, somnolence, coma, and potentially death. A clinical hallmark is the onset of symptoms within 24 hours of ingestion of acetaminophen medications. Ingestion should be treated before symptoms develop if possible.
- Acetaminophen poisoning most often occurs following large, single ingestions of acetaminophen-containing medications. Toxic doses are typically >10 g in adults and >200 mg/kg in children. Poisoning also occurs after acute and chronic ingestions of lesser amounts in individuals who regularly abuse alcohol, are chronically malnourished, or take medications that affect hepatic metabolism of acetaminophen.
- Therapeutic adult doses are 0.5 to 1.0 g q4–6h to a maximum of 4 g/day. Therapeutic pediatric doses are 10 to 15 mg/kg q4–6h, not to exceed 5 doses in 24 hours or 75 g/kg/day.
- System(s) affected: gastrointestinal, cardiovascular, renal/urologic, central nervous system
  - Multisystem organ failure can occur.
- Synonym(s): paracetamol poisoning

Geriatric Considerations
Increased risk of hepatic damage in frail elderly patients due to decreased hepatic metabolism and coingestion of other hepatotoxic medications. Keep dose of acetaminophen ≤3,000 mg/day in seniors and patients with liver disease and/or alcohol abuse disorders.

Pediatric Considerations
Hepatic damage after ingestion of toxic acetaminophen doses can be less severe in young children, potentially due to larger glutathione stores.

Pregnancy Considerations
Increased incidence of spontaneous abortion, especially with overdose at an early gestational age. Incidence of spontaneous abortion or fetal death is increased when N-acetylcysteine (NAC) treatment is delayed. IV NAC is generally preferred in pregnancy due to greater bioavailability.

EPIDEMIOLOGY
- Predominant age: children and adults
- Predominant sex: no reported association
- Intentional versus unintentional ingestion (52% vs. 48%)

Incidence
The annual reported incidence of acetaminophen overdosing increased from 2 (95% CI 0.2–7.2) cases per 10,000 patients in 2005 to 3.4 (95% CI 1.1–8.8) in 2010.

Prevalence
- >38,000 hospitalizations per year for acetaminophen-related poisonings in the United States,
nearly 1/2 were unintentional (mostly involving opioid–acetaminophen combinations).
- <1% of hospitalizations in patients <18 years had coexistent liver toxicity.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Accidental or intentional ingestion of acetaminophen medications
- 96% of ingested acetaminophen is metabolized in the liver, only 2–4% is excreted unchanged in the urine. When taken in therapeutic doses, 90–95% of hepatic metabolism results in the formation of benign metabolites. 5–10% of hepatic metabolism is by oxidation through the cytochrome P450 enzyme system (CYP 3A4 and CYP 2E1), resulting in the formation of the toxic metabolite N-acetyl-p-benzoquinone imine (NAPQI). NAPQI is rapidly conjugated with glutathione to form a nontoxic metabolite. Metabolites are excreted in the urine with a small amount of unchanged drug. Hepatocellular damage occurs when toxic doses of acetaminophen saturate the glucuronidation and sulfation pathways with production of excessive NAPQI. Available glutathione stores become depleted, NAPQI accumulates, and hepatocellular damage occurs.

**RISK FACTORS**
- Concurrent poisoning with other substances
- Psychiatric illness, history of suicide attempts
- Regular ingestion of large amounts of alcohol
- Possible risk related to previous weight loss surgery

**GENERAL PREVENTION**
- Poison Control: 1-800-222-1222 for consultations and management guidance

**DIAGNOSIS**
- May initially be asymptomatic, particularly with history of ingestion in preceding 8 hours. Signs and symptoms of poisoning are related to liver toxicity and develop over the first 24 hours following large ingestions; may last up to 8 days
- Symptoms may develop gradually following long-term ingestion of near maximal-therapeutic amounts of acetaminophen. Such patients may present in varying stages, without a history of toxic ingestion.
- Severe symptoms indicate large ingestions or coingestants.
  - Stage 1: first 24 hours after ingestion:
    - Nausea, emesis, and anorexia
    - Diaphoresis
  - Stage 2: days 2 to 3 following ingestion
    - Right upper quadrant pain
    - Typically less nausea, vomiting, diaphoresis, and malaise than in stage 1
  - Stage 3: days 3 to 4 following ingestion
    - Nausea, vomiting, and malaise reappear.
    - Severe poisonings may result in jaundice, confusion, somnolence, and coma.
  - Stage 4: 5 or more days after ingestion
    - Possible deterioration due to multiorgan failure and death. Symptoms resolve over time in
survivors.
- Fulminant hepatic failure occurs in <1% of adults and is very rare in children <6 years of age.
- An unexplained rise in liver function tests (LFTs) with negative acetaminophen levels might suggest stage 3 toxicity.

**HISTORY**
Ingestion or suspected ingestion of acetaminophen-containing product

**PHYSICAL EXAM**
Depends on duration after ingestion. Vital signs. Hemodynamic stability. Signs of hepatotoxicity

**DIFFERENTIAL DIAGNOSIS**
- Consider presence of coingestants, especially alcohol, opiates, and aspirin.
- Other ingested toxins that produce severe acute hepatic injury, including the mushroom Amanita phalloides and products containing yellow phosphorus or carbon tetrachloride

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Draw plasma acetaminophen levels on all patients ≥4 hours after ingestion (levels prior to 4 hours are not useful). Draw additional levels at 6 and 8 hours if extended release form.
- Alanine transaminase (ALT), aspartate transaminase (AST), prothrombin time (PT)/international normalized ratio (INR), bilirubin, lactate dehydrogenase (LDH)
  - With severe poisonings, PT/INR rise in parallel with LFT changes.
  - With toxic ingestions, AST (serum glutamic-oxaloacetic transaminase), ALT (serum glutamic-pyruvic transaminase), and bilirubin levels begin to rise in stage 2 and peak in stage 3.
  - Improvement in ALT with therapy is an encouraging clinical sign.
- Electrolytes, glucose, BUN, creatinine
  - Renal function abnormalities are common in patients with hepatotoxicity.
- Pregnancy screen in females (urine or serum)
- Urinalysis
- Consider arterial blood gas (ABG).
  - Anion-gap metabolic acidosis due to accumulation of 5-oxoproline may rarely be seen.
- Screen for suspected coingestants (aspirin, iron, etc.), especially if suicide gesture/attempt.
- Laboratory abnormalities usually resolve by stage 4.
- Cardiovascular, renal, and pancreatic involvement may present following severe poisonings.
- Diseases or toxic substances that damage the liver (particularly alcohol) may alter laboratory results.
- No specific imaging required

**Follow-Up Tests & Special Considerations**
During recovery, liver tests should normalize.

**Test Interpretation**
Centrilobular hepatic necrosis
TREATMENT

- Contact a regional/local poison control center for recommendations. In the United States: 1-800-222-1222
- Give acetylcysteine (NAC) when plasma acetaminophen concentrations measured ≥4 hours after ingestion are in the “possible risk” or higher levels on the Rumack-Matthew nomogram. This corresponds to acetaminophen levels >150 μg/mL (993 μmol/L), >75 μg/mL (497 μmol/L), and >37 μg/mL (244 μmol/L) at 4, 8, and 12 hours after ingestion, respectively. See http://www.ars-informatica.ca/toxicity_nomogram.php?calc=acetamin.
- Consideration: The nomogram does not help determining the need for NAC for sustained-release products or chronic ingestions. If a sustained-released product has been ingested, obtain two serum acetaminophen levels 4 to 6 hours apart. Treat if either level is above the possible toxicity line. For chronic toxicity or patients who present 24 hours postingestion, treat based on clinical effects, LFTs, and the acetaminophen level.
- Start NAC within 8 hours of ingestion for maximal hepatic protection. Patients presenting near 8 hours should empirically receive NAC while waiting for labs.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.
- NAC therapy may be effective up to ≥36 hours after ingestion.
- Give single-dose activated charcoal within 1 to 2 hours (and possibly up to 4 hours) of ingestion (especially in cases of coingestants) (1,2)[C].

ALERT

Never delay NAC administration for use of activated charcoal.

- Ipecac and gastric lavage are no longer recommended for routine use at home or in health care facilities.

MEDICATION

First Line

- Initiate acetylcysteine (NAC, Mucomyst) within 8 hours of ingestion whenever possible; single-dose activated charcoal (1 g/kg PO) may be effective if given within 1 to 2 hours of ingestion especially if other substances concomitantly ingested. Never delay oral NAC for activated charcoal.
- NAC may be given PO or IV, depending on situation and availability:
  - A 2-bag regimen should be used to administer a total of 300 mg/kg IV NAC (Acetadote, Cetylev) over a 20-hour period to reduce adverse effects of NAC administration. Begin with a 200 mg/kg IV dose over 4 hours. Followed by a 100 mg/kg IV dose over 16 hours. (3,4)
  - Oral loading dose of 140 mg/kg, then 70 mg/kg q4h for 17 additional doses (72-hour regimen)
- No treatment regimen has been shown to be superior over the other (1)[A]. However, IV NAC has been shown to decrease the length of hospitalization compared to oral NAC.

Contraindications: medication allergies

Precautions:
  - Oral NAC may cause significant nausea and vomiting due to its sulfur content and is often poorly tolerated; consider nasogastric tube.
  - Nausea can be treated with metoclopramide (Reglan), 1 to 2 mg/kg IV, or ondansetron (Zofran), 0.15 mg/kg IV (for age >4 years, usually 4 mg/dose).
- IV NAC (Acetadote) may cause anaphylactoid reactions, (3–6%) including rash, bronchospasm, pruritus, angioedema, tachycardia, or hypotension (higher rates seen in asthmatics and those with atopy) (5)[C].
  - Reactions usually occur with loading dose. To prevent this, slow or temporarily stop the infusion; may concurrently treat with antihistamines.
  - Failure rates of NAC of 3–7% have been observed (5)[C].

**Second Line**
- Oral racemethionine (methionine)
- In massive ingestions (levels >1,000 mg/L, acidosis, coma/hypotension), hemodialysis may improve survival (6)[C].
- In January 2016, NAC (Acetadote, Cetylev), an effervescent lemon mint–flavored NAC tablet, was approved by the FDA. Tablets come in strengths of 500 mg and 2.5 g.

**ISSUES FOR REFERRAL**
- Behavioral health evaluation for intentional ingestions
- Child abuse reporting if neglect led to overdose

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Toxic and intentional ingestions
- Increased LFTs, acidosis on ABG, elevated creatinine, or other signs of target organ damage merit admission.
- Age- and weight-appropriate IV hydration

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Evaluate all patients at an accredited health care facility; escalate level of care as appropriate depending on potential level of toxicity.
- Evaluate patients with evidence of organ failure, increased LFTs, or coagulopathy for emergency liver transplant (ELT) at a transplant center.
- Restrict activity if hepatic damage is significant.
- Outpatient management is adequate for nontoxic accidental ingestions.

**Patient Monitoring**
Ask about ingestion by others (i.e., suicide pacts).

**DIET**
No special diet, except with severe hepatic damage

**PATIENT EDUCATION**
- Counsel patients to avoid acetaminophen (Tylenol, others) or other forms of acetaminophen, particularly if using combination product(s) containing acetaminophen.
- Educate parents/caregivers during well-child visits.
- Anticipatory guidance for caregivers, family, and cohabitants of potentially suicidal patients
- Educate patients on long-term acetaminophen therapy.

**PROGNOSIS**
Complete recovery with early therapy

- <1% of adult patients develop hepatic failure. King criteria (pH <7.3, PT >100 s [INR >65], creatinine >3.4 mg/dL [>300 μmol/L]) is associated with a poor prognosis and possible need for liver transplant (7)[C]. Early referral increases the chance for transplant success.
- Hepatic failure is very rare in children <6 years of age.

**COMPLICATIONS**

Rare following recovery from acute poisoning

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- T39.1X4A Poisoning by 4-Aminophenol derivatives, undetermined, init
- K71.10 Toxic liver disease with hepatic necrosis, without coma
- T39.1X1A Poisoning by 4-Aminophenol derivatives, accidental, init
CLINICAL PEARLS

- Consult Poison Control Center for management recommendations, 1-800-222-1222 in United States.
- Give NAC when plasma acetaminophen concentrations (measured ≥4 hours after ingestion) are in the “possible risk” or higher levels. This corresponds to acetaminophen levels >150 μg/mL (993 μmol/L), >75 μg/mL (497 μmol/L), and >37 μg/mL (265 μmol/L) at 4, 8, and 12 hours after ingestion, respectively.
- Start NAC within 8 hours of ingestion for best chance of hepatic protection. Empirically give NAC in patients presenting near 8 hours while waiting for labs. A 2-bag IV dosing regimen over 20 hours is preferred.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.
- If using oral NAC, dilute with a beverage to increase palatability. Serve in a cup with lid and straw.
- For extended release acetaminophen, follow plasma levels at 4, 6, and 8 hours after ingestion. Start NAC if any level is elevated.
ACNE ROSACEA
Daniel R. DiBlasi, DO ● Shane L. Larson, MD

BASICS

DESCRIPTION
- Rosacea is a chronic condition characterized by recurrent episodes of facial flushing, erythema (due to dilatation of small blood vessels in the face), papules, pustules, and telangiectasia (due to increased reactivity of capillaries) in a symmetric, central facial distribution; sometimes associated with ocular symptoms (ocular rosacea)
- Four subtypes:
  - Erythematotelangiectatic rosacea (ETR)
  - Papulopustular rosacea (PPR)
  - Phymatous rosacea
  - Ocular rosacea
- System(s) affected: skin/exocrine
- Synonym(s): rosacea

Geriatric Considerations
- Chronic inflammatory dermatosis with middle-age onset
- Effects of aging might increase the side effects associated with oral isotretinoin used for treatment (at present, data are insufficient due to lack of clinical studies in elderly patients ≥65 years).

EPIDEMIOLOGY

Prevalence
- Predominant age of onset: 30 to 50 years
- Predominant sex: female > male. However, males are at greater risk for progression to later stages.
- More common in Fitzpatrick skin types I and II

ETIOLOGY AND PATHOPHYSIOLOGY
- No proven cause
- Possibilities include the following:
  - Thyroid and sex hormone disturbance
  - Alcohol, coffee, tea, spiced food overindulgence (unproven)
  - Demodex follicular parasite (suspected)
  - Exposure to cold, heat
  - Emotional stress
  - Dysfunction of the GI tract (possible association with Helicobacter pylori)

Genetics
- People of Northern European and Celtic background commonly afflicted
- Associated with three human leukocyte antigen (HLA) alleles: HLA-DRB1, HLA-DQB1, and HLA-DQA1 (MHC class II)
RISK FACTORS
- Exposure to spicy foods, hot drinks
- Environmental factors: sun, wind, cold, heat

GENERAL PREVENTION
No preventive measures known

COMMONLY ASSOCIATED CONDITIONS
- Seborrheic dermatitis of scalp and eyelids
- Keratitis with photophobia, lacrimation, visual disturbance
- Corneal lesions
- Blepharitis
- Uveitis

DIAGNOSIS

HISTORY
- Usually have a history of episodic flushing with increases in skin temperature in response to heat stimulus in mouth (hot liquids), spicy foods, alcohol, sun exposure
- Acne may have preceded onset of rosacea by years; nevertheless, rosacea usually arises de novo without preceding history of acne or seborrhea.
- Excessive facial warmth and redness are the predominant presenting complaints. Itching is generally absent.

PHYSICAL EXAM
- Rosacea has four subtypes:
  - The rosacea diathesis: episodic erythema, “flushing and blushing”
  - Progression from one subtype to another is hypothetical.
  - ETR: persistent erythema with telangiectases
  - PPR: persistent erythema, telangiectases, papules, pustules
  - Phymatous: persistent deep erythema, dense telangiectases, papules, pustules, nodules; rarely persistent “solid” edema of the central part of the face (phymatous)
- Facial erythema, particularly on cheeks, nose, and chin. At times, entire face may be involved.
- Inflammatory papules are prominent; pustules and telangiectasia may be present.
- Comedones are absent (unlike acne vulgaris).
- Women usually have lesions on the chin and cheeks, whereas the nose is commonly involved in men.
- Ocular findings (mild dryness and irritation with blepharitis, conjunctival injection, burning, stinging, tearing, eyelid inflammation, swelling, and redness) are present in 50% of patients.

DIFFERENTIAL DIAGNOSIS
- Drug eruptions (iodides and bromides)
- Granulomas of the skin
- Cutaneous lupus erythematosus
- Carcinoid syndrome
- Acne vulgaris
- Seborrheic dermatitis
Steroid rosacea (abuse)
Systemic lupus erythematosus
Lupus pernio (sarcoidosis)

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis is based on physical exam findings.
A recent change in classification has been proposed based on the phenotype that reflects the clinical presentation and to better focus treatment options, which are targeted to address the main clinical presentation (1).

Test Interpretation
Histology of affected skin may reveal:
- Inflammation around hypertrophied sebaceous glands, producing papules, pustules, and cysts
- Absence of comedones and blocked ducts
- Vascular dilatation and dermal lymphocytic infiltrate
- Granulomatous inflammation

TREATMENT
GENERAL MEASURES
- Proper skin care and photoprotection are important components of management plan (1)[B]. Use of mild, nondrying soap is recommended; local skin irritants should be avoided.
- Avoidance of triggers
- Reassurance that rosacea is completely unrelated to poor hygiene
- Treat psychological stress if present.
- Topical steroids should not be used because they may aggravate rosacea.
- Avoid oil-based cosmetics:
  - Others are acceptable and may help women tolerate symptoms.
- Electrodesiccation or chemical sclerosis of permanently dilated blood vessels
- Possible evolving laser therapy
- Support physical fitness.

MEDICATION
First Line
- Topical metronidazole preparations once (1% formulation) or twice (0.75% formulations) daily for 7 to 12 weeks was significantly more effective than placebo in patients with moderate to severe rosacea. A rosacea treatment system (cleanser, metronidazole 0.75% gel, hydrating complexion corrector, and sunscreen SPF 30) may offer superior efficacy and tolerability to metronidazole (2)[A].
- Azelaic acid (Finacea) is very effective as initial therapy; azelaic acid topical alone is effective for maintenance (3)[B].
- Topical ivermectin 1% cream (2)[A]
  - Recently found to be more effective than metronidazole for treatment of PPR
- Topical brimonidine tartrate 0.5% gel is effective in reducing erythema associated with ETR (4)[A].
  - \(\alpha_2\)-Adrenergic receptor agonist; potent vasoconstrictor
Oxymetazoline 1% cream, an α1A-adrenergic receptor agonist recently approved for the treatment of persistent erythema associated with rosacea in adults (5)[B].

Doxycycline 40-mg dose is at least as effective as 100-mg dose and has a correspondingly lower risk of adverse effects but is much more expensive (6)[A].

Precautions: Tetracyclines may cause photosensitivity; sunscreen is recommended.

Significant possible interactions:
- Tetracyclines: Avoid concurrent administration with antacids, dairy products, or iron.
- Broad-spectrum antibiotics: may reduce the effectiveness of oral contraceptives; however, this finding has only been associated with rifampin; consider adding barrier method.

**Second Line**
- Topical erythromycin
- Topical clindamycin (lotion preferred)
  - Can be used in combination with benzoyl peroxide; commercial topical combinations are available.
- Possible use of calcineurin inhibitors (tacrolimus 0.1%; pimecrolimus 1%). Pimecrolimus 1% is effective to treat mild to moderate inflammatory rosacea.
- Permethrin 5% cream; similar efficacy compared to metronidazole for severe cases, oral isotretinoin at 0.3 mg/kg for a minimum of 3 months

**Pediatric Considerations**
Tetracyclines: not for use in children <8 years

**Pregnancy Considerations**
- Tetracyclines: not for use during pregnancy
- Isotretinoin: teratogenic; not for use during pregnancy or in women of reproductive age who are not using reliable contraception; requires registration with iPLEDGE program

**ADDITIONAL THERAPIES**
Cyclosporine 0.05% ophthalmic emulsion may be more effective than artificial tears for ocular rosacea.

**SURGERY/OTHER PROCEDURES**
Laser treatment is an option for progressive telangiectasias or rhinophyma.
- Pulsed dye laser (585 nm or 595 nm) is effective in treating telangiectases and erythema.
- CO2 fractional ablative laser can be used to treat rhinophyma.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Outpatient treatment

**Patient Monitoring**
- Occasional and as needed
- Close follow-up and laboratory assessment for patients using isotretinoin per prescribing instructions and iPLEDGE program guidance
- Consider ophthalmology evaluation in patients with ocular symptoms.
DIET
Avoid alcohol and hot drinks of any type.

PROGNOSIS
- Slowly progressive
- Subsides spontaneously (sometimes)

COMPLICATIONS
- Rhinophyma (dilated follicles and thickened bulbous skin on nose), especially in men
- Conjunctivitis
- Blepharitis
- Keratitis
- Visual deterioration

REFERENCES

ADDITIONAL READING
SEE ALSO

- Acne Vulgaris; Blepharitis; Dermatitis, Seborrheic; Lupus Erythematosus, Discoid; Uveitis
- Algorithm: Acne

CODES

ICD10

- L71.9 Rosacea, unspecified
- L71.8 Other rosacea

CLINICAL PEARLS

- Rosacea usually arises de novo without any preceding history of acne or seborrhea.
- Rosacea may cause chronic eye symptoms, including blepharitis.
- Avoid alcohol, sun exposure, and hot drinks.
- Medication treatment resembles that of acne vulgaris, with oral and topical antibiotics.
ACNE VULGARIS
Gary I. Levine, MD

BASICS

DESCRIPTION
- Acne vulgaris is a disorder of the pilosebaceous units. It is a chronic inflammatory dermatosis notable for open/closed comedones, papules, pustules, nodules.
- Systems affected: skin/exocrine

Geriatric Considerations
Favre-Racouchot syndrome: comedones on face and head due to sun exposure

Pregnancy Considerations
- May result in a flare or remission of acne
- Typically improves in 1st trimester; may worsen in 3rd trimester
- Topical benzoyl peroxide, azelaic acid, erythromycin or clindamycin, and oral erythromycin or cephalaxin can be used in pregnancy; use topical agents when possible.
- Isotretinoin is teratogenic; pregnancy Category X
- Avoid topical tretinoin and adapalene because they may cause retinoid embryopathy; class C
- Contraindicated: isotretinoin, tazarotene, tetracycline, doxycycline, minocycline

Pediatric Considerations
- Neonatal acne (neonatal cephalic pustulosis)
  - Newborn to 8 weeks; lesions limited to face; usually self-limited, may respond to topical ketoconazole 2% cream (1,2)
- Infantile acne
  - Newborn to 1 year; lesions on face, neck, back, and chest; topical/systemic Rx (1)
- Early to middle childhood acne
  - 1 to 7 years; rare; consider hyperandrogenism (1).
- Preadolescent acne
  - 7 to 12 years; common, 47% of children, usually due to adrenal awakening, comedonal lesions
  - Do not use tetracyclines in those <8 years of age (1); other therapies similar to adolescent acne

EPIDEMIOLOGY
- Predominant age: early to late puberty, may persist in 20–40% of affected individuals into 4th decade
- Predominant sex
  - Male > female (adolescence)
  - Female > male (adult)

Prevalence
- 80–95% of adolescents affected. A smaller percentage will seek medical advice.
- 8% of adults aged 25 to 34 years; 3% at 35 to 44 years
- African Americans 37%, Caucasians 24%
ETIOLOGY AND PATHOPHYSIOLOGY
- Androgens (testosterone and dehydroepiandrosterone sulfate [DHEA-S]) stimulate sebum production/qualitative sebum changes and proliferation of keratinocytes in hair follicles (3).
- Keratin plug obstructs follicle os, causing sebum accumulation and follicular distention.
- Propionibacterium acnes (Cutibacterium acnes phylotype Ia), an anaerobe, colonizes and proliferates within a biofilm in the plugged follicle.
- P. acnes promote proinflammatory mediators, causing inflammation of follicle and dermis.

Genetics
- Familial association in 50%
- If a family history exists, the acne may be more severe and occur earlier.

RISK FACTORS
- Increased endogenous androgenic effect
- Oily cosmetics, cocoa butter
- Rubbing or occluding skin surface (e.g., sports equipment such as helmets and shoulder pads), telephone, or hands against the skin
- Polyvinyl chloride, chlorinated hydrocarbons, cutting oil, tars
- Numerous drugs, including androgenic steroids (e.g., steroid abuse, some birth control pills), lithium, phenytoin
- Endocrine disorders: polycystic ovarian syndrome, Cushing syndrome, congenital adrenal hyperplasia, androgen-secreting tumors, acromegaly
- Stress
- High-glycemic load, possibly high-dairy diets (skim milk), and whey protein supplements may exacerbate acne (3).
- Severe acne may worsen with smoking.

COMMONLY ASSOCIATED CONDITIONS
- Acne fulminans, pyoderma faciale
- Acne conglobata, hidradenitis suppurativa
- Pomade acne
- SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis)
- Pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA) and seborrhea, acne, hirsutism, and alopecia (SAHA) syndromes
- Behçet syndrome, Apert syndrome
- Dark-skinned patients: 50% keloidal scarring and 50% acne hyperpigmented macules

DIAGNOSIS

HISTORY
- Ask about duration, medications, cleansing products, stress, smoking, exposures, diet, and family history.
- Females may worsen 1 week prior to menses.

PHYSICAL EXAM
- Closed comedones (whiteheads)
- Open comedones (blackheads)
- Nodules or papules
- Pustules (“cysts”)
- Scars: ice pick, rolling, boxcar, atrophic macules, hypertrophic, depressed, sinus tracts
- Consistent grading is useful; no specific universal grading system is recommended per guidelines (4).
- Grading system (American Academy of Dermatology, 1990) (3)
  - Mild: few papules/pustules; no nodules
  - Moderate: some papules/pustules; few nodules
  - Severe: numerous papules/pustules/nodules
  - Very severe: acne conglobata, acne fulminans, acne inversa
- Most common areas affected are face, chest, back, and upper arms (areas of greatest concentration of sebaceous glands) (3).
- Adult female—facial lesion distribution not limited to mandibular and perioral lesion location, similar to adolescents

**DIFFERENTIAL DIAGNOSIS**
- Folliculitis: gram-negative and gram-positive
- Acne (rosacea, cosmetica, steroid induced)
- Perioral dermatitis
- Chloracne
- Pseudofolliculitis barbae
- Drug eruption
- Verruca vulgaris and plana
- Keratosis pilaris
- Molluscum contagiosum
- Sarcoïdosis
- Seborrheic dermatitis
- Miliaria
- Lupus erythematosus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Only indicated if additional signs of androgen excess; if so, test for free and total testosterone and DHEA-S and consider luteinizing hormone and follicle-stimulating hormone (polycystic ovary syndrome).

**TREATMENT**
- Comedonal (grade 1): keratinolytic agent (see as follows for specific agents)
- Mild inflammatory acne (grade 2): benzoyl peroxide or topical retinoid or benzoyl peroxide +/- topical antibiotic +/- topical retinoid
- Moderate inflammatory acne (grade 3): Add time-limited systemic antibiotic to grade 2 regimen.
- Severe inflammatory acne (grade 4): as in grade 3, or isotretinoin
- Topical retinoid plus a topical antimicrobial agent (such as BP) is first-line treatment for more than mild disease.
Topical retinoid + antibiotic (topical or PO) is better than either alone for mild/moderate acne. Topical retinoids are first-line agents for maintenance therapy. Avoid long-term antibiotics for maintenance.

Avoid oral or topical antibiotics as monotherapy. Use with topical BP +/- topical retinoid (4) [A].

Can use isotretinoin for treatment of resistant moderate acne (4)

Recommended vehicle type
- Dry or sensitive skin: cream, lotion, or ointment
- Oily skin, humid weather: gel, solution, or wash
- Hair-bearing areas: lotion, hydrogel, or foam

Apply topical agents to entire affected area, not just visible lesions.

Mild soap daily to control oiliness; avoid abrasives.

Avoid drying agents with keratinolytic agents.

Gentle cleanser and noncomedogenic moisturizer help decrease irritation.

Oil-free, noncomedogenic sunscreens

Stress management if acne flares with stress

MEDICATION

ALERT
Most prescription branded topical medications are very expensive, costing from $100 to several hundred dollars per tube. OTC versions of azelaic acid and adapalene are now available and much less expensive.

Keratinolytic agents (α-hydroxy acids, salicylic acid, topical retinoids, azelaic acid) (side effects include dryness, erythema, and scaling; start with lower strength or alternate day Rx, increase as tolerated.)

Tretinoin (Retin-A, Retin-A Micro, Avita, Atralin) varying strengths and formulations: Apply pea-sized dose at bedtime; wash skin; let skin dry 30 minutes before application.
- Retin-A Micro, Atralin, and Avita are less irritating and stable with BP.
- May cause an initial flare of lesions; may be eased by every other day application for first 2 to 4 weeks
- Avoid in pregnant and lactating women.
- Cost varies based on formulation—$50 to $150 per tube for generic.

Adapalene (Differin): 0.1%, apply topically at night.
- Effective; less irritation than tretinoin or tazarotene
- May be combined with benzoyl peroxide (Epiduo)- 0.1 or 0.3%/2.5%—very effective in skin of color
- First FDA-approved over-the-counter (OTC) retinoid much less expensive than other Rx retinoids ($10 to $15 per tube)

Tazarotene (Tazorac): Apply at bedtime.
- Most effective and most irritating; teratogenic

Azelaic acid (Azelex, Finevin): 20% topically, BID
- Keratinolytic, antibacterial, anti-inflammatory
- Reduces postinflammatory hyperpigmentation in dark-skinned individuals
- Side effects: erythema, dryness, scaling, hypopigmentation
- Effective in postadolescent acne
- Safe in pregnancy—risk category B

No
- 20% Rx >$400 per tube
- OTC 10% and 15% formulations cost $10 to $40 per tube.

- Salicylic acid: 2%, less effective and less irritating than tretinoin
- α-Hydroxy acids: available OTC

Topical antibiotics and anti-inflammatories
- Topical benzoyl peroxide
  - No resistance in P. acnes
  - 2.5% as effective as stronger preparations
  - Gel penetrates better into follicles.
  - When used with tretinoin, apply benzoyl peroxide in morning and tretinoin at night.
  - Side effects: concentration-dependent irritation; may bleach clothes; photosensitivity

Topical antibiotics: Do not use as monotherapy (4)[A].
- Erythromycin 2%
- Clindamycin 1%
- Metronidazole gel or cream: Apply once daily.
- Benzoyl peroxide-erythromycin (Benzamycin): especially effective with azelaic acid
- Benzoyl peroxide-clindamycin (BenzaClin, DUAC, Clindoxyl)
- Benzoyl peroxide-salicylic acid (Cleanse & Treat, Inova): similar in effectiveness to benzoyl peroxide-clindamycin
- Sodium sulfacetamide (Sulfacet-R, Novacet, Klaron): useful in acne with seborrheic dermatitis or rosacea
- Dapsone (Aczone) 5% gel: useful in adult females with inflammatory acne; may cause yellow/orange skin discoloration when mixed with BP; very rare methemoglobinemia

Oral antibiotics: use for shortest possible period, generally needs 6 to 12 weeks of therapy, limit to 3 months if possible, max 6 months if necessary (4); indicated when acne is more severe, trunk involvement, unresponsive to topical agents, or at greater risk for scarring, do not use as monotherapy
- Tetracycline: 500 to 1,000 mg/day divided BID; high dose initially, taper in 6 months, less effective than doxycycline or minocycline (4), side effects: photosensitivity, esophagitis
- Minocycline: 100 to 200 mg/day, divided daily—BID; side effects include photosensitivity, urticaria, gray-blue skin, vertigo, hepatitis, lupus.
- Doxycycline: 20 to 200 mg/day, divided daily—BID; side effects include photosensitivity.
- Erythromycin: 500 to 1,000 mg/day; divided BID–QID; decreasing effectiveness as a result of increasing P. acnes resistance
- Trimethoprim-sulfamethoxazole (Bactrim DS, Septra DS): 1 daily or BID
- Azithromycin (Zithromax): 500 mg 3 days/week × 1 month and then 250 mg every other day × 2 months

Oral retinoids
- Isotretinoin: 0.5 to 1.0 mg/kg/day divided BID to maximum 2 mg/kg/day divided BID for very severe disease; 60–90% cure rate; usually given for 12 to 20 weeks; maximum cumulative dose = 120 to 150 mg/kg; 20% of patients relapse and require retreatment (3) [A], 0.25 to 0.40 mg/kg/day in moderately severe acne
  - Side effects: teratogenic, pancreatitis, excessive drying of skin, hypertriglyceridemia, hepatitis, blood dyscrasias, hyperostosis, premature epiphyseal closure, night blindness, erythema multiforme, Stevens-Johnson syndrome, possible suicidal ideation, psychosis
  - Avoid tetracyclines or vitamin A during isotretinoin
Monitor for pregnancy, psychiatric/mood changes, CBC, lipids, glucose, and LFTs at baseline and every month.

Patient and provider must register iPLEDGE program (www.ipledgeprogram.com); two forms of effective contraception required.

- Medications for women only
  - FDA-approved oral contraceptives (in order of possible effectiveness) (5)[B]
    - Drospirenone/ethinyl estradiol (Yaz), or drospirenone/ethinyl estradiol/levomefolate (Beyaz) > norgetimate/ethinyl estradiol (Ortho Tri-Cyclen) > norethindrone acetate/ethinyl estradiol (Estrostep)
  - Most combined contraceptives also effective; may take 3 to 6 months to become effective

- Spironolactone (Aldactone); 25 to 200 mg/day; antiandrogen; reduces sebum production, not FDA-approved for acne Rx

**ISSUES FOR REFERRAL**
Management of acne scars

**ADDITIONAL THERAPIES**
- Acne hyperpigmented macules
  - Topical hydroquinones (1.5–10%)
  - Azelaic acid (20%) topically
  - Topical retinoids
  - Corticosteroids: low dose
  - Dapsone 5% gel (Aczone): topical, anti-inflammatory; use in patients >12 years.
  - Sunscreen for prevention
- Light-based treatments
  - Ultraviolet A/ultraviolet B (UVA/UVB), blue or blue/red light; pulse dye, KTP, or infrared laser
  - Photodynamic therapy with 5-aminolevulinic acid has best evidence.

**SURGERY/OTHER PROCEDURES**
- Comedo extraction after incising the layer of epithelium over closed comedo
- Inject large cystic lesions with 0.05 to 0.30 mL triamcinolone (Kenalog 2 to 5 mg/mL); use 30-gauge needle, inject through pore, slightly distend cyst.
- Acne scar treatment: retinoids, steroid injections, cryosurgery, electrodessication, micro-/dermabrasion, chemical peels, laser resurfacing, pulsed dye laser, microneedling, fillers, punch elevation

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Evidence suggests tea tree oil, seaweed extract, Kampo formulations, Ayurvedic formulations, rose extract, basil extract, epigallocatechin gallate, barberry extract, gluconolactone solution, and green tea extract may be useful (4).
- Limited data on use of dermocosmetics for acne Rx

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Limit use of oral to 3 months; taper topical antibiotic (6,7) as inflammatory lesions resolve.
DIET
Data suggests that high-glycemic index foods and skim milk may worsen acne (4)[B].

PATIENT EDUCATION
● There may be a worsening of acne during first 2 weeks of treatment.
● Results are typically seen after a minimum of 4 weeks of treatment.

PROGNOSIS
Gradual improvement over time (usually within 8 to 12 weeks after beginning therapy)

COMPLICATIONS
● Acne conglobata: severe confluent inflammatory acne with systemic symptoms
● Facial scarring and psychological distress, including anxiety, depression, and suicidal ideation (3)
● Postinflammatory hyperpigmentation, keloids, and scars are more common in skin of color.

REFERENCES

SEE ALSO
● Acne Rosacea
● Algorithm: Acne

CODES
ICD10
● L70.0 Acne vulgaris

CLINICAL PEARLS
● Full results for changes in therapy take 8 to 12 weeks.
• Decrease topical frequency to every day or to every other day for irritation.
• Use benzoyl peroxide every time a topical or oral antibiotic is used.
ACUTE CORONARY SYNDROMES: NSTE-ACS (UNSTABLE ANGINA AND NSTEMI)
Shawn J. John, MBBS, BSc Hons • Naureen Rafiq, MBBS

BASICS

DESCRIPTION
- Unstable angina (UA) and non–ST-segment elevation myocardial infarction (NSTEMI) are acute coronary syndromes without ST-segment elevation (NSTE-ACS).
- NSTEMI is defined by the rise and fall of cardiac biomarkers (preferably troponin) with at least one value above the 99th percentile upper reference limit and accompanied by one of the following: symptoms of ischemia, new ST-segment/T-wave changes (such as ST depression or T-wave inversions), development of pathologic Q waves on ECG, or imaging evidence of loss of viable myocardium or new regional wall motion abnormality.
- UA is defined by the presence of clinical symptoms of cardiac ischemia (new-onset anginal chest pain, change in typical anginal pattern, development of angina at rest, or change in typical anginal equivalent), without myocardial necrosis as evidenced by normal cardiac biomarkers of injury (troponin). ECG changes, such as ST-segment depression or T-wave inversions, may be present.

EPIDEMIOLOGY

Incidence
- Estimated annual incidence of new and recurrent MI is 605,000 and 200,000, respectively (1).
- In United States, average age at first MI is 65.6 years for males and 72.0 years for females (1).
- Incidence of MI is higher in blacks across all age groups as compared to the white population, with the highest incidence in black males (1).

Prevalence
- An estimated 16.5 million Americans ≥20 years have coronary artery disease (CAD) with the overall prevalence of MI being 3.0% (3.8% for males and 2.3% for females) (1).
- Mortality
  - CAD is the leading cause of death in adults in the United States with overall age-adjusted mortality of 98.8/100,000 (1).
  - Death rate is higher in men as compared to women and in blacks as compared to whites (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- NSTE-ACS occurs primarily due to a sudden decrease in myocardial blood flow due to acute plaque rupture or plaque erosions leading to partially occluding thrombosis.
- Other mechanisms include:
  - Dynamic obstruction triggered by intense spasm of a coronary artery (Prinzmetal angina or coronary vasospasm induced by cocaine or methamphetamine)
  - Increased myocardial oxygen demand resulting in supply–demand mismatch, microcirculatory dysfunction without epicardial coronary obstruction
  - Less common causes include coronary arterial inflammation, dissection/rupture, thromboembolism.
Genetics

- Chromosome 9p21.3 has been the most frequently associated genetic marker for MI in European-derived populations and is also associated with coronary heart disease in patients of East Asian descent (1).
- Furthermore, chromosome 9p21.3 has been associated with premature atherosclerosis, peripheral arterial disease, heart failure, ischemic stroke, and aortic aneurysm (1).

RISK FACTORS

- Traditional/classic
  - Age (strongest risk factor), male gender, prior MI, hypertension, tobacco use, diabetes mellitus (DM), dyslipidemia, and family history of premature CAD (Premature CAD is defined as age of onset prior to 55 years in males and <65 years in females.)
- Novel/emerging risk factors
  - Sedentary lifestyle, overweight/obesity (metabolic syndrome), inflammation (psoriasis, rheumatoid arthritis), psychosocial factors (anxiety/depression), chronic kidney disease (CKD), obstructive sleep apnea, higher intake of red meat, radiation exposure

GENERAL PREVENTION

- Smoking cessation, healthy diet, weight control, physical activity
- Risk factor control: diabetes and blood pressure control, lipid-lowering therapy (statins), daily aspirin (in select patients)

COMMONLY ASSOCIATED CONDITIONS

- Vascular disease (cerebrovascular and peripheral vascular disease, aneurysms, erectile dysfunction)
- Other forms of heart disease (heart failure, valvular disease, high-output states)
- Disease related to underlying risk factors: chronic obstructive pulmonary disease and thrombophilic disorders

DIAGNOSIS

HISTORY

- Chest heaviness/tightness lasting ≥10 minutes; occurs with or without exertion, may increase in frequency. Pain or discomfort is typically retrosternal and can radiate to the neck, jaw, interscapular area, upper extremities, or epigastrium.
- Pain is typically described as a pressure, tightness, heaviness, squeezing, or fullness.
- Associated symptoms of palpitations, dyspnea, nausea, diaphoresis, light-headedness, syncope, or dysphoria can occur.
- Patients especially elderly, diabetics, and women can present without chest pain with symptoms such as dyspnea, diaphoresis, and extreme fatigue which represent “anginal equivalents.”
- Risk factors for CAD
- Use of cocaine or amphetamines

PHYSICAL EXAM

- General: abnormal vital signs including tachycardia or bradycardia, hypertension or hypotension, widened pulse pressure, tachypnea, fever, transverse ear crease, poor dental
hygiene, stigmata of tobacco use

- Cardiovascular: dysrhythmia, jugular venous distention (JVD), new murmur, rub or gallop, diminished peripheral pulses, carotid bruits
- Respiratory: tachypnea, ↑ work of breathing, crackles
- Neurologic: fatigue, weakness, altered mental status
- Musculoskeletal: Sharp pain reproducible with movement or palpation is unlikely to be cardiac.
- Skin: cool skin, pallor, diaphoresis, signs of dyslipidemia (xanthomas, xanthelasma)

DIFFERENTIAL DIAGNOSIS

- Cardiac: aortic dissection, myocarditis, pericarditis, pericardial effusion/tamponade, heart failure, hypertensive emergency, stress cardiomyopathy (Takotsubo), dysrhythmia, and mitral valve disease
- Pulmonary: pulmonary embolism, pneumothorax, pneumonia, pleuritis, bronchitis
- Panic disorder and anxiety disorders
- Musculoskeletal pain: costochondritis, rib fracture
- GI: gastroesophageal reflux disease (GERD), esophageal spasm, esophagitis, esophageal rupture or perforation, hiatal hernia, penetrating or perforating peptic ulcer, biliary or pancreatic pain

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- 12-lead ECG: should be obtained within 10 minutes of presentation; applies to both UA and NSTEMI
  - New ST-segment depression ≥0.5 mm in two or more contiguous leads and/or T-wave inversions ≥1 mm in two or more contiguous leads with prominent R wave or R/S ratio >1
  - ST depression and/or tall R wave in V1/V2 with upright T waves may indicate transmural STEMI of posterior wall. ECG with posterior leads (V7–V9) should be performed.
  - If initial ECG is nondiagnostic but symptoms persist with suspicion for ACS, perform serial ECGs at 15- to 30-minute intervals.
- Complete blood count, bone morphogenic proteins, and serum biomarker (negative by definition in UA)
  - Troponin concentration rises 3 to 6 hours after onset of ischemic symptoms but can be delayed up to 8 to 12 hours (troponin T is not specific in patients with renal dysfunction).
  - Ultra-high sensitive troponins have a higher sensitivity than standard assays, but further validation is required.
  - With contemporary troponin assays, older cardiac markers of injury-like lactate dehydrogenase, creatine kinase-MB (CK-MB), and myoglobin are much less sensitive and specific and have limited utility in the routine management of ACS. CK-MB has been shown to have better specificity than troponins in post-PCI MI.
  - Patients with negative biomarkers within 6 hours of the onset of symptoms should have biomarkers remeasured 8 to 12 hours from onset of symptoms.
- Chest x-ray, computed tomography with contrast to exclude other etiologies
- Transthoracic echocardiography is recommended to assess for regional wall motion abnormalities, systolic function, and to exclude alternate etiologies.

Follow-Up Tests & Special Considerations
• Fasting lipid profile, preferably within 24 hours
• Activated partial thromboplastin time (aPTT)
• Urine drug screen in selected patients
• TSH if symptoms of hyperthyroidism
• Other lab tests: B-type natriuretic peptide or N-terminal pro–B-type natriuretic peptide; increases with MI and may not indicate heart failure

**Diagnostic Procedures/Other**
• For low- to intermediate-risk patients with resolution of symptoms and nondiagnostic ECG with negative biomarkers, consider noninvasive cardiac testing with standard exercise treadmill test, stress echocardiography, or nuclear stress study.
• Alternatively, coronary computed tomography angiography can be performed as well to exclude NSTE-ACS.

![TREATMENT]

**GENERAL MEASURES**
• Risk stratify using TIMI or GRACE score to select use of early invasive approach (coronary angiography within 24 hours of admission) versus ischemia-guided therapy
  – Urgent invasive management for very high-risk patients, such as those with hemodynamic instability or cardiogenic shock, recurrent or ongoing chest pain refractory to medical therapy, life-threatening arrhythmias or cardiac arrest, mechanical complications, acute heart failure, and recurrent dynamic ST-T wave changes
• Bed/chair rest with continuous ECG monitoring, maintain O₂ saturation >90%, and tight BP control
• Avoid continuation of NSAIDs.
• Deep vein thrombosis prophylaxis
• Smoking cessation
• Correction of electrolyte abnormalities (K and Mg)

**MEDICATION**

**First Line**
• Antiplatelet therapy: Dual antiplatelet therapy is recommended for all patients with NSTE-ACS.
• Aspirin, nonenteric coated, initial dose of 162 to 325 mg chewed or crushed for all patients; decreases mortality and morbidity
• Maintenance dose of 75 to 100 mg/day indefinitely
• P2Y12 inhibitors:
  – Should be given at the time of diagnosis unless invasive approach is planned in a very high–bleeding-risk patient
  – Ticagrelor, loading dose 180 mg PO, followed by 90 mg PO twice daily; avoid in patients with 2nd- and 3rd-degree heart block OR
  – Prasugrel 60 mg PO, followed by 10 mg PO daily. Reserved for post-PCI patients treated with coronary stents; contraindicated in patients ≥75 years or those with history of CVA/TIA OR
  – Clopidogrel, loading dose 300 to 600 mg PO, followed by 75 mg PO daily. Use with
caution in patients with thrombocytopenia and CKD.
- Patients unable to take aspirin should receive loading and maintenance dose of a P2Y12 inhibitor.
- GP IIb/IIIa inhibitors: Add eptifibatide or tirobotabin in select high-risk patients (persistent chest pain, large thrombus burden on angiography) after PCI.

- Supplemental oxygen may be given if oxygen saturations are less than 90% or in patients with heart failure symptoms.
- Nitroglycerin sublingual 0.4 mg every 5 minutes for total of 3 doses and then assess need for IV nitroglycerin. Avoid if hypotension or if used phosphodiesterase inhibitors within the past 24 to 48 hours.
- Morphine sulfate 1 to 5 mg IV in patients with continuous ischemic chest pain, with increments of 2 to 8 mg repeated at 5- to 30-minute intervals
- Oral β-blocker therapy should be initiated within 24 hours in patients without signs of heart failure, cardiogenic shock, or other contraindications to beta-blockade (2nd or 3rd degree heart block without a pacemaker, active asthma). Recommended dose is metoprolol tartrate 25 to 50 mg every 6 to 12 hours or atenolol 25 to 50 mg twice daily. IV therapy may be considered in patients with severe ischemia.
- In patients with concomitant ACS, stabilized heart failure, and reduced systolic function (LVEF <40%), the recommended β-blockers are metoprolol succinate, carvedilol, and bisoprolol.
- Lipid-lowering therapy: Initiate or continue high-intensity statin therapy (preferred due to nonlipid benefit on vascular function) with atorvastatin 80 mg daily or rosuvastatin 20 to 40 mg daily regardless of the patient’s baseline LDL level. Ezetimibe, omega-3 fatty acids, PCSK9 inhibitors (evolocumab, alirocumab), and/or fibrates can be considered in statin-intolerant patients.
- ACE inhibitor (ACEi) is recommended in all patients with ACS particularly in the presence of diabetes, LV dysfunction, or heart failure.
- Aldosterone antagonist (spironolactone or eplerenone) is recommended in NSTEMI for patients without significant renal dysfunction or hyperkalemia who are on a therapeutic dose of ACEi/ARB and β-blocker and have LVEF ≤40%, DM, or heart failure.
- Antithrombotic therapy: Initiate anticoagulant: enoxaparin or unfractionated heparin (UFH), fondaparinux, or bivalirudin. Bivalirudin has been associated with a lower bleeding risk.

**Second Line**
- Nondihydropyridine calcium channel blocker (CCB) (verapamil or diltiazem) to reduce myocardial oxygen demand when β-blockers are contraindicated if normal ejection fraction (EF). Use oral long-acting CCB only after β-blockers and nitrates have been fully used. Long-acting CCBs are recommended in treatment of patients with coronary artery spasm. Avoid in patients with heart block.
- Long-term nitrate therapy for recurrent angina/ischemia or heart failure
- Sublingual nitroglycerin at discharge
- Ranolazine indicated in treatment of chronic angina not responsive to other meds; 500 to 1,000 mg, twice a day
- Benzodiazepines in patients with cocaine/methamphetamine intoxication. Avoid β-blockers in cocaine or methamphetamine users.

**ISSUES FOR REFERRAL**
Cardiology consultation is appropriate for NSTE-ACS.
Patients will need close follow-up with a cardiologist.
Referral to exercise-based cardiac rehabilitation program prior to hospital discharge

SURGERY/OTHER PROCEDURES
Coronary reperfusion strategies include:
– PCI with stent placement
– CABG surgery
Intra-aortic balloon pump for patients may be performed with refractory symptoms/shock

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admit patients with risk factors who present with chest pain and suspected NSTE-ACS.
Considerations in special populations
– Older population (≥75 years)
  o Benefit of early invasive management in elderly ≥ young population
  o Pharmacotherapy should be individualized based on weight and renal function.
– Pregnancy
  o Specific risk factors for ACS in pregnancy include advanced maternal age, gestational diabetes, and preeclampsia/eclampsia.
  o Spontaneous coronary artery dissection and thromboembolism should be considered in evaluation of pregnant women with ACS.
  o ACEi, ARBs, and statins are contraindicated.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
It is reasonable in patients with suspected ACS (low risk) who have normal serial ECGs and cardiac troponins to have a treadmill ECG, stress myocardial perfusion imaging, or stress echocardiography before or within 72 hours after discharge.
Follow up 2 to 6 weeks (low risk) and 14 days (high risk).
All patients with reduced EF need reevaluation for implantable cardioverter defibrillator placement for primary prevention >40 days to 3 months (postrevascularization) after discharge.

DIET
Diet relationship to CAD is complex; patients should maintain a diet low in saturated and trans fats, low in sodium, and high in fiber.

PATIENT EDUCATION
Education on diet, exercise, smoking cessation, and lifestyle modification. It is safe to resume exercise, sexual activity within 2 weeks in asymptomatic patients after outpatient reevaluation.
Recommend pneumococcal and influenza vaccination.

PROGNOSIS
UA/NSTEMI patients have lower in-hospital mortality than those with STEMI but a similar or worse long-term outcome.
COMPLICATIONS
Cardiogenic shock, heart failure, mitral regurgitation, ventricular aneurysm, dysrhythmia, acute pulmonary embolism, acute thromboembolic stroke, pericarditis/Dressler syndrome, depression (increases mortality risk)

REFERENCES

CODES
ICD10
- I24.9 Acute ischemic heart disease, unspecified
- I20.0 Unstable angina
- I21.4 Non-ST elevation (NSTEMI) myocardial infarction

CLINICAL PEARLS
- Discontinue NSAIDs, nonselective or selective cyclooxygenase (COX)-2 agents, except for acetylsalicylic acid, due to increased risks of mortality, reinfarction, hypertension, heart failure, and myocardial rupture.
- Discontinue clopidogrel or prasugrel or ticagrelor 5 to 7 days before elective CABG.
- Dual anti-platelet therapy, antithrombotic therapy, β-blocker, high-dose statin therapy, and nitrates are the cornerstones of initial therapy and should be initiated promptly.
- Duration of antithrombotic therapy after NSTEMI depends on type of stent received and medications administered.
- Avoid β-blockers in cocaine or methamphetamine users.
ACUTE CORONARY SYNDROMES: STEMI
Yutthapong Temtanakitpaisan, MD ● Adedotun Anthony Ogunsua, MD, MPH ● Kimberly Atianzar, MD

BASICS

DESCRIPTION
Acute myocardial infarction (AMI) is the rapid development of myocardial necrosis resulting from a sustained and complete absence of blood flow to a portion of the myocardium. ST-segment elevation myocardial infarction (STEMI) occurs when coronary blood flow ceases, usually following complete atherothrombotic occlusion of a large coronary artery, resulting in transmural ischemia. This is accompanied by release of serum cardiac biomarkers and ST-segment elevation on an electrocardiogram (ECG).

EPIDEMIOLOGY

Incidence
There are >650,000 cases of AMI reported annually in the United States. Early revascularization and AMI management has improved mortality, with a 30-day survival of 95%.

Prevalence
● Leading cause of morbidity and mortality in the United States
● ~7.5 million people in the United States are affected by AMI.
● Prevalence increases with age and is higher in men (5.5%) compared to women (2.9%).

ETIOLOGY AND PATHOPHYSIOLOGY

● Atherosclerotic coronary artery disease (CAD):
  – Atherosclerotic lesions can be fibrotic, calcified, or lipid laden. Thin-capped atheromas are more likely to rupture, causing atherothrombotic occlusion.
● Nonatherosclerotic causes:
  – Embolism from either infective vegetations, or thrombi originating within the right atrium across the foramen ovale (“paradoxical”), from the left atrium or from within the left ventricle
  – Spontaneous coronary artery dissection: prevalent in fibromuscular dysplasia (FMD) and in young women
  – Mechanical or iatrogenic obstruction: chest trauma, dissection of the aorta and/or coronary arteries
  – Coronary artery spasm from increased vasomotor tone; anginal variant
  – Arteritis and other etiologies: hematologic causes (disseminated intravascular coagulation [DIC], severe anemia), aortic stenosis, cocaine, IV drug use, severe burns, prolonged hypotension

RISK FACTORS
Advancing age, hypertension, tobacco use, diabetes mellitus, dyslipidemia, family history of premature onset of CAD, sedentary lifestyle

GENERAL PREVENTION
Smoking cessation/abstinence; healthy diet; weight loss/control; regular physical activity and exercise; control of hypertension, hyperlipidemia, and diabetes mellitus

**COMMONLY ASSOCIATED CONDITIONS**
Abdominal aortic aneurysm, cerebrovascular disease, atherosclerotic peripheral vascular disease

---

**DIAGNOSIS**

**HISTORY**
- Symptoms:
  - Classically, sudden onset of chest heaviness/tightness, with or without exertion, lasting minutes to hours
  - Pain/discomfort radiating to neck, jaw, interscapular area, upper extremities, and/or epigastrium
  - Patients with inferior MI may present primarily with abdominal discomfort.
- Previous history of myocardial ischemia (stable or unstable angina, AMI, coronary bypass surgery, or percutaneous coronary intervention [PCI])
- Assess risk factors for CAD, history of bleeding, noncardiac surgery, family history of premature CAD.
- Medications: Ask if recent use of phosphodiesterase type 5 inhibitors (if recent use, avoid concomitant nitrates).
- Tobacco, alcohol, and/or drug abuse (especially cocaine)

**PHYSICAL EXAM**
- General: restlessness, agitation, hypothermia, fever
- Neurologic: dizziness, syncope, fatigue, asthenia, disorientation (especially in the elderly)
- Cardiovascular (CV): dysrhythmia, hypotension, widened pulse pressure, S3 and S4, jugular venous distention (JVD)
- Respiratory: dyspnea, tachypnea, crackles, rales
- GI: abdominal pain, nausea, vomiting, hiccups
- Musculoskeletal: pain in neck, back, shoulders, or upper limbs
- Skin: cool skin, pallor, diaphoresis

**Geriatric and Gender Considerations**
- Elderly patients may have an atypical presentation, including silent or unrecognized MI. They may often present with syncope, weakness, shortness of breath, unexplained nausea, epigastric pain, altered mental status, or delirium.
- Women may present with typical and/or “atypical” symptoms such as fatigue, dyspnea, and malaise.
- Patients with diabetes mellitus may have fewer and less dramatic chest symptoms.

**DIFFERENTIAL DIAGNOSIS**
Unstable angina, aortic dissection, pulmonary embolism (PE), perforating gastric ulcer, pericarditis, dysrhythmias, gastroesophageal reflux disease (GERD), esophageal spasm, biliary/pancreatic pain, hyperventilation syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**
- **12-lead ECG:**
  - ≥1 mm ST elevation in a regional pattern, involving at least two contiguous leads, with or without abnormal Q waves
  - STEMI of posterior wall: ST depression ± tall R waves in V₁–V₂
  - Absence of Q waves represents partial or transient occlusion or early infarction.
  - Consider right-sided and posterior chest leads if inferior MI pattern (examine V₃R, V₄R, V₇–V₉).
  - In the setting of ventricular pacing or a prior left bundle branch block, the Sgarbossa criteria may be helpful.
- 2-Dimensional transthoracic echocardiography is useful in evaluating regional wall motion in MI and left ventricular function.
  - Useful in assessing mechanical complications and mural thrombus
- Once diagnosis is suspected, emergent coronary angiography with PCI is preferred.

**Follow-Up Tests & Special Considerations**
- Serum biomarkers
  - Troponin I and T (cTnI, cTnT) rise 3 to 6 hours after onset of ischemic symptoms.
  - Elevations in cTnI persist for 7 to 10 days, whereas cTnT elevations persist for 10 to 14 days after MI.
  - Myoglobin fraction of creatine kinase-MB (CK-MB) rises 3 to 4 hours after onset of myocardial injury; peaks at 12 to 24 hours and remains elevated for 2 to 3 days; CK-MB adds little diagnostic value in assessment of possible AMI to troponin testing.
- Other pertinent labs: fasting lipid profile, complete blood count (CBC), electrolytes, magnesium, blood urea nitrogen, serum creatinine, glucose, hemoglobin A1C, international normalized ratio (INR) if anticoagulation is contemplated, brain natriuretic peptide (BNP)
- Gender and minorities considerations
  - It is important to note that women and minorities receive less treatment compared with men and Caucasians.

**Pregnancy Considerations**
Pregnant patients presenting with STEMI will need discussion of risks and benefits of invasive coronary angiography with radiation exposure to fetus. Management should otherwise be the same as in nonpregnant patients.

**Diagnostic Procedures/Other**
- High-quality portable chest x-ray; transthoracic and/or transesophageal echocardiography; chest computed tomography angiography (CTA) scan may occasionally be of value acutely in equivocal presentations to evaluate for alternative diagnoses (aortic dissection, PE, ventricular aneurysm).
- Coronary angiography is the definitive test.

**ALERT**
Patients with chronic kidney disease need special attention to amount of contrast media used. Reduced volume of contrast and use of low or isosmolar contrast media may lower risk of progression of renal impairment.
TREATMENT

GENERAL MEASURES

- See “Medication” for ED management.
- Following emergent revascularization, admit the patient to the coronary care unit (CCU) or a telemetry unit with continuous ECG monitoring and bed rest, and use:
  - Anxiolytics, if needed; stool softeners
  - Antiarrhythmics as needed for unstable dysrhythmia
  - Deep vein thrombosis (DVT) prophylaxis
  - Dual antiplatelet therapy (DAPT) with continuation of aspirin 81 mg/day with clopidogrel 75 mg/day or prasugrel 10 mg/day or ticagrelor 90 mg twice daily
  - β-Blocker (BB), ACE inhibitors (or ARB if ACE intolerant), high intensity statin
  - Tight BP control, progressively increased physical activity, smoking cessation/abstinence

MEDICATION

Medication recommendations are based on the 2013 American College of Cardiology (ACC)/American Heart Association (AHA) guideline and 2017 European Society of Cardiology (ESC) guideline (1).

First Line
(While awaiting revascularization)

- Supplemental oxygen 2 to 4 L/min for patients with oxygen saturation <90% or respiratory distress
- Nitroglycerin (NTG) sublingual 0.4 mg q5min for a total of 3 doses, followed by nitroglycerin IV if ongoing pain and/or hypertension and/or management of pulmonary congestion if no contraindications exist such as systolic <90 mm Hg or >30 mm Hg below baseline, right ventricle (RV) infarct, use of sildenafil or vardenafil within 24 hours or within 48 hours of tadalafil
- Morphine sulfate 4 to 8 mg IV with 2 to 8 mg IV repeated at 5- to 15-minute intervals to relieve pain, anxiety, or pulmonary congestion
- Antiplatelet agents:
  - Aspirin (ASA), non-enteric-coated, initial dose 162 to 325 mg chewed
  - A loading dose of a P2Y12 inhibitor is recommended for patients with STEMI for whom PCI is planned. Prasugrel or ticagrelor is preferred.
    - Prasugrel 60 mg loading dose should be given as soon as possible for primary PCI. Prasugrel is contraindicated in patients with previous stroke/transient ischemic attack. Do not recommend in patients aged >75 years or lower body weight (<60 kg).
    - Ticagrelor 180 mg loading dose. Ticagrelor may cause transient dyspnea.
    - Clopidogrel 600 mg loading dose should be given if neither prasugrel nor ticagrelor is available.
    - Cangrelor may be considered in patients not pretreated with oral P2Y12 receptor inhibitors at the time of PCI or in those who are unable to take oral agents.
  - Duration of DAPT is controversial. Standard recommendation is 6–12 months after PCI, depending on bleeding and ischemia risks, but newer generation stents may not require DAPT longer than 1 month.
- Anticoagulation therapy:
Unfractionated heparin (UFH) 70- to 100-U/kg IV bolus
- Enoxaparin 0.5-mg/kg IV bolus
- Bivalirudin 0.75-mg/kg IV bolus and then 1.75-mg/kg/hr infusion for up to 4 hours after procedure

PCI versus fibrinolysis: Goal is to keep total ischemic time within 120 minutes. Door to needle time should be within 30 minutes or door to balloon time within 90 minutes.

- Coronary reperfusion therapy
  - Primary PCI (balloon angioplasty, coronary stents) in the following:
    - Symptom onset of ≤12 hours
    - Symptom onset of ≤12 hours and contraindication to fibrinolytic therapy irrespective of time delay
    - Cardiogenic shock or acute severe heart failure (HF) irrespective of time delay from onset of MI
    - Evidence of ongoing ischemia 12 to 24 hours after symptom onset
  - Radial access is recommended over femoral access.

- Procedural considerations
  - Routine aspiration thrombectomy is no longer recommended prior to PCI because usefulness and safety are not fully established.
  - PCI of infarct-related artery (IRA) is indicated.
  - Routine revascularization of non-IRA lesions in cardiogenic shock is not recommended during primary PCI.

- Fibrinolysis
  - If presenting to a hospital without PCI capability and cannot be transferred to a PCI-capable facility to undergo PCI within 120 minutes of first medical contact
  - If no contraindications, administer within 12 to 24 hours of symptom onset, if there is evidence of ongoing ischemia.
    - Alteplase (tPA): 15-mg IV bolus, followed by 0.75 mg/kg (up to 50 mg) IV over 30 minutes and then 0.5 mg/kg (up to 35 mg) over 60 minutes; maximum 100 mg over 90 minutes
    - Reteplase (rPA): 10 units IV bolus; give second bolus 30 minutes apart.
    - Tenecteplase (TNK-tPA): 30- to 50-mg (based on weight) IV bolus. Recommend to reduce to half dose in patients ≥75 years of age.
  - Adjunctive antiplatelet therapy with fibrinolysis
    - Aspirin: 162- to 325-mg loading dose followed by 81 mg daily indefinitely
    - Clopidogrel (300-mg loading dose for patients <75 years of age, 75-mg dose for patients >75 years of age). Clopidogrel 75 mg daily should be continued for at least 14 days and up to 1 year.
  - Adjunctive anticoagulation therapy with fibrinolysis
    - Use anticoagulants (UFH, enoxaparin, or fondaparinux) as ancillary therapy to reperfusion therapy for minimum of 48 hours and preferably duration of admission (up to 8 days) or until revascularization, if performed.

- Glycoprotein IIb/IIIa receptor antagonists at time of primary PCI in selected patients if there is no reflow or thrombotic complications (abciximab, eptifibatide, or tirofiban)

- IV β-blocker should be considered at the time of presentation, if no contraindications exist (signs of congestive heart failure [CHF], low output state) and systolic blood pressure >120 mm Hg.
ACE inhibitors should be initiated orally within 24 hours of STEMI in patients with anterior infarction, HF, diabetes, or ejection fraction (EF) ≤0.40 unless contraindicated.

High-intensity statin therapy should be started as early as possible.

Mineralocorticoid receptor antagonist (spironolactone, eplerenone) is recommended in patients with EF <40% and HF or diabetes, who are already receiving an ACE inhibitor and a BB, if there is no renal failure or hyperkalemia.

**Second Line**

Long-acting nondihydropyridine calcium channel blocker (CCB) when BB is ineffective or contraindicated and EF is normal; do not use immediate-release nifedipine.

**ISSUES FOR REFERRAL**

Transfer high-risk patients who receive fibrinolytic therapy as primary reperfusion therapy at a non-PCI capable facility to a PCI-capable facility as soon as possible.

**SURGERY/OTHER PROCEDURES**

Urgent coronary artery bypass graft (CABG) surgery is indicated in patients with STEMI and coronary anatomy not amenable to PCI who have ongoing or recurrent ischemia, cardiogenic shock, severe HF, or other high-risk features.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- All STEMI patients should be admitted to a CCU or an intensive cardiac care unit for evaluation and treatment.
- Right ventricular infarction may need fluid resuscitation for hypotension.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- STEMI patients should follow up with a cardiologist 1–2 weeks postdischarge, every 3 months for the first year, and then yearly.
- Emphasize medication adherence and encourage smoking cessation.
- In patient with left ventricular ejection fraction equal or less than 40%, repeat echocardiography 6–12 weeks after AMI or after complete revascularization, is recommended to assess the potential need for primary prevention implantable cardioverter defibrillator implantation.
- Consider an exercise-based cardiac rehabilitation program.

**DIET**

Low-fat/healthy-fat diet: reduced intake of saturated fats (to <7% of total calories) (but dairy fats are possibly not associated with CAD), eliminate trans fatty acids (to <1% of total calories). Impact of low-cholesterol diet remains uncertain. Mediterranean diet is healthy.

**PATIENT EDUCATION**

May resume sexual activity 1 or more weeks after uncomplicated MI or 6 to 8 weeks after CABG; smoking cessation and low-fat diet
PROGNOSIS
Poor prognosis is associated with advanced age, diabetes, delayed or unsuccessful revascularization, reduced left ventricular systolic function, and evidence of congestive heart failure.

COMPLICATIONS
HF, myocardial wall rupture, left ventricular aneurysm, pericarditis, dysrhythmias, acute mitral regurgitation, and depression (common)

REFERENCES

CODES
ICD10
- I24.9 Acute ischemic heart disease, unspecified
- I21.3 ST elevation (STEMI) myocardial infarction of unspecified site
- I25.10 Atherosclerotic heart disease of native coronary artery w/o ang pectrs

CLINICAL PEARLS
- STEMI occurs from occlusion of one or more coronary arteries resulting in transmural myocardial ischemia.
- Early revascularization with percutaneous coronary intervention (PCI) within 90 minutes of presentation at a PCI capable hospital is required, or within 120 minutes if transfer to a PCI-capable hospital is required.
- Fibrinolytic therapy should be initiated within 30 minutes if presenting to a hospital without PCI capability and cannot be transferred to a PCI-capable facility to undergo PCI within 120 minutes of first medical contact.
- Duration of dual antiplatelet therapy should be determined based on an individualized risk assessment of ischemia and bleeding, and also considering type of intervention (PCI, CABG) undertaken.
ACUTE KIDNEY INJURY
Pratha Muthiah, MD, MPH ● Jason Chao, MD, MS

 BASICS
DESCRIPTION
Abrupt loss of kidney function, defined as a rise in serum creatinine (SCr) of ≥0.3 mg/dL within 48 hours; a 50% increase in SCr within 7 days or urine output of <0.5 mL/kg/hr for >6 hours, resulting in retention of nitrogenous waste as well as electrolyte, acid–base, and volume homeostasis abnormalities (1)

EPIDEMIOLOGY
Incidence
● 5% of hospital and 30% of intensive care unit admissions have acute kidney injury (AKI). 25% of patients develop AKI while in the hospital; 50% of these cases are iatrogenic.
● Developing AKI as an inpatient is associated with >4-fold increased risk of death (2).

ETIOLOGY AND PATHOPHYSIOLOGY
Three categories: prerenal, intrarenal, and postrenal
● Prerenal (reduced renal perfusion, typically reversible)
  – Hypotension, volume depletion (gastrointestinal [GI] losses, excessive sweating, diuretics, hemorrhage); renal artery stenosis/embolism; burns; heart/liver failure
  – Decreased renal perfusion (often due to hypovolemia) leads to a decrease in glomerular filtration rate (GFR), which (if prolonged or severe) can progress to ischemic acute tubular necrosis (ATN).
● Intrarenal (intrinsic kidney injury, often from prolonged or severe renal hypoperfusion)
  – ATN (from prolonged prerenal azotemia, radiographic contrast material, aminoglycosides, nonsteroidal anti-inflammatory drugs (NSAIDs), or other nephrotoxic substances), glomerulonephritis (GN), acute interstitial nephritis (AIN; drug induced), arteriolar insults, vasculitis, accelerated hypertension, cholesterol embolization (following an intra-arterial procedure), intrarenal deposition/sludging (uric acid nephropathy and multiple myeloma [Bence Jones proteins])
● Postrenal (obstruction of the collecting system)
  – Extrinsic compression (e.g., benign prostatic hypertrophy [BPH], carcinoma, pregnancy); intrinsic obstruction (e.g., calculus, tumor, clot, stricture, sloughed papillae); decreased function (e.g., neurogenic bladder), leading to obstruction of the urinary collection system

Genetics
No known genetic pattern

RISK FACTORS
● Chronic kidney disease (CKD)
● Comorbid conditions (e.g., diabetes mellitus, hypertension, heart failure, liver failure)
● Advanced age
● Radiocontrast material exposure (intravascular)
● Medications that impair autoregulation of GFR (NSAIDs, angiotensin-converting enzyme
inhibitors (ACEI), angiotensin II receptor blockers (ARB), cyclosporine/tacrolimus
- Nephrotoxic medications (e.g., aminoglycoside antibiotics, platinum-based chemotherapy)
- Hypovolemia (e.g., diuretics, hemorrhage, GI losses)
- Sepsis, surgery, rhabdomyolysis
- Solitary kidney (risk in nephrolithiasis)
- BPH; malignancy (e.g., multiple myeloma)

COMMONLY ASSOCIATED CONDITIONS
Hyperkalemia, hyperphosphatemia, hypercalcemia, hyperuricemia, hydronephrosis, BPH, nephrolithiasis, congestive heart failure (CHF), uremic pericarditis, cirrhosis, CKD, malignant hypertension, vasculitis, drug reactions, sepsis, severe trauma, burns, transfusion reactions, recent chemotherapy, rhabdomyolysis, internal bleeding, dehydration

DIAGNOSIS
AKI is usually asymptomatic until the patient has experienced extreme loss of function. Oliguria can be present, but it is neither specific nor sensitive (3).

HISTORY
- Ascertain changes in oral intake, urine output, and body weight
- Thorough medication history
- Prerenal: thirst, orthostatic symptoms
- Intrarenal: nephrotoxic medications, radiocontrast material, other toxins
- Livedo reticularis, subcutaneous (SC) nodules, and ischemic digits despite good pulses suggest atheroembolization
- Flank pain may suggest renal artery or vein occlusion
- Postrenal: Colicky flank pain that radiates to the groin suggests ureteric obstruction such as a stone; nocturia, frequency, and hesitancy suggest prostatic disease; suprapubic and flank pain are usually secondary to distension of the bladder and collecting system; anticholinergic drugs inhibit bladder emptying
- Uremic symptoms: lethargy, nausea/vomiting, anorexia, pruritus, restless legs, sleep disturbance, hiccups

PHYSICAL EXAM
- Uremic signs: altered sensorium, seizures, asterixis, myoclonus, pericardial friction rub, peripheral neuropathies
- Prerenal signs: tachycardia, decreased jugular venous pressure (JVP), orthostatic hypotension, dry mucous membranes, decreased skin turgor; comorbid stigmata of sepsis, liver disease, or heart failure
- Intrinsic renal signs: pruritic rash, livedo reticularis, SC nodules, ischemic digits despite good pulses
- Postrenal signs: suprapubic distension, flank pain, enlarged prostate

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Compare to baseline renal function (creatinine [Cr]/GFR) (1)[A]
- Urinalysis: dipstick for blood and protein; microscopy for cells, casts, and crystals (1)[A]
Sterile pyuria (especially white blood cell [WBC] casts) suggests AIN; triad of fever, rash, and eosinophilia present in 10% of cases

Proteinuria, hematuria, and edema, often with nephritic urine sediment (red blood cells [RBCs] and RBC casts), suggest GN or vasculitis.

Casts: transparent hyaline casts—prerenal etiology; pigmented granular/muddy brown casts—ATN; WBC casts—AIN; RBC casts—GN

Urine eosinophils: ≥1% eosinophils suggest AIN (poor sensitivity).

Urine electrolytes in an oliguric state
- FENa = \[(U_{Na} \times P_{Cr}) / (P_{Na} \times U_{Cr})\] × 100
  - FENa <1%, likely prerenal; >2%, likely intrarenal
  - If patient on diuretics, use FE_{urea} instead of FE_{Na}: FE_{urea} = \[(U_{urea} \times P_{Cr}) / (P_{BUN} \times U_{Cr})\] × 100; FE_{urea} <35% suggests prerenal etiology.

Complete blood count, blood urea nitrogen (BUN), SCr, electrolytes (including Ca/Mg/P); consider arterial or venous blood gas (ABG/VBG).

BUN/Cr ratio not reliable in distinguishing prerenal azotemia from AKI (4)[B]

- Increased: potassium, phosphate, magnesium, uric acid
- Decreased: hemoglobin, sodium calcium

Calculate creatinine clearance (CrCl) to ensure appropriate medication dosing

Imaging:
- Renal ultrasound (US): first line; excludes postrenal causes; identifies kidney size, hydronephrosis, and nephrolithiasis
- Doppler-flow renal US: evaluates for renal artery stenosis/thrombosis; operator dependent
- Abdominal x-ray (kidney, ureter, bladder [KUB]): identifies calcification, renal calculi, kidney size

Novel biomarkers such as urinary IL-18, neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), plasma cystatin C, TIMP-2, and IGFBP7 under investigation (5)[C]

Follow-Up Tests & Special Considerations

- Consider creatine kinase (rhabdomyolysis) and immunologic testing (if GN or vasculitis suspected).
- Advanced imaging if initial tests unrevealing
  - Prerenal: US as effective as computed tomography (CT) for obstruction
  - Noncontrast helical CT: most sensitive test for nephrolithiasis
  - Radionuclide renal scan: evaluates renal perfusion, function (GFR), and presence of obstructive uropathy and extravasation
  - Magnetic resonance imaging: acute tubulointerstitial nephritis with increased T2-weighted signal. Gadolinium contrast is contraindicated if GFR <30 mL/min due to risk of nephrogenic systemic fibrosis.

Diagnostic Procedures/Other

Cystoscopy with retrograde pyelogram evaluates for bladder tumor, hydronephrosis, obstruction, and upper tract abnormalities without risk of contrast nephropathy.

Test Interpretation

Kidney biopsy: last resort if patient does not respond to therapy or if diagnosis remains unclear;
most useful to evaluate intrinsic AKI of unclear cause (AIN, GN, vasculitis, or renal transplant rejection)

**TREATMENT**

Fluid resuscitation is the mainstay of treatment of AKI, both in prerenal and intrinsic kidney injury. In severe cases of kidney injury, dialysis may be required, especially in cases where the patient is oliguric. The most important aspect of treating AKI is determining the underlying cause.

**GENERAL MEASURES**

Identify and correct prerenal and postrenal causes
- Stop nephrotoxic drugs and renally dose others
- Strictly monitor intake/output and daily weight
- Optimize cardiac output to maintain renal perfusion
- Optimize nutrition and treat any infections
- Indications for renal replacement therapy (RRT): volume overload, severe or progressive hyperkalemia, or severe metabolic acidosis refractory to medical management; advanced uremic complications (pericarditis, encephalopathy, bleeding diathesis)

**MEDICATION**

**First Line**
- Find and treat the underlying cause.
- Prevent fluid overload, and correct electrolyte imbalances—particularly hyperkalemia.
  - If patient is oliguric and not volume overloaded, a monitored fluid challenge may help.
- Furosemide is ineffective in preventing and treating AKI but can (judiciously) be used to manage volume overload and/or hyperkalemia. Furosemide stress test may predict the likelihood of progressive AKI, need for RRT, and mortality (5)[B].
- Dopamine, natriuretic peptides, insulin-like growth factor, and thyroxine have no benefit in the treatment of AKI.
- Fenoldopam, a dopamine agonist, has been equivocal in decreasing risk of RRT and mortality in AKI; not currently recommended (1)[C]
- Hyperkalemia with ECG changes: Give IV calcium gluconate, isotonic sodium bicarbonate (only if acidemic, and avoid use of hypertonic “amps” of NaHCO₃), glucose with insulin, and/or high-dose nebulized albuterol (to drive K⁺ into cells); Kayexalate and/or furosemide (to increase K⁺ excretion); hemodialysis if severe/refractory
- Fluid restriction may be required for oliguric patients to prevent worsening hyponatremia.
- Metabolic acidosis (particularly pH <7.2): Sodium bicarbonate can be given (judiciously); be aware of volume overload, hypocalcemia, and hypokalemia.
- Effective strategies for AKI prevention: isotonic in vitro fertilization, once-daily dosing of aminoglycosides; use of lipid formulations of amphotericin B, use of iso-osmolar nonionic contrast media
- Risk of contrast-induced AKI reduced by avoidance of hypovolemia: isotonic saline 1 mL/kg/hr morning of procedure and continued until next morning or isotonic NaHCO₃ 3 mL/kg/hr × 1 hour before and 1 mL/kg/hr × 6 hours after contrast administration; N-acetylcysteine not of benefit
Second Line
- Tamsulosin or other selective α-blockers for bladder outlet obstruction secondary to BPH
- Dihydropyridine calcium channel blockers may have a protective effect in posttransplant ATN.

ISSUES FOR REFERRAL
- Consider nephrology consultation.
- Urology consults for obstructive nephropathy

SURGERY/OTHER PROCEDURES
- Relieve obstruction by retrograde ureteral catheters/percutaneous nephrostomy.
- Hemodialysis catheter placement

COMPLEMENTARY & ALTERNATIVE MEDICINE
Many herbal and dietary supplements are potentially nephrotoxic (aristolochic acid, ochratoxin A, Djenkol bean, impila, orellanine, cat’s claw). Obtain a thorough medication history from the patient.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Treat life-threatening complications: hyperkalemia, metabolic acidosis, volume overload, and advanced uremia.
- If hypovolemic, give isotonic IV fluids.
- Monitor fluid balance and daily weights.
- Consider urinary catheter placement to quantify urine output, weighing risks of catheter-associated urinary tract infection (CAUTI). Remove as soon as possible.
- Stabilize renal function and ensure treatment plan prior to discharge.
- Dialysis if necessary

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Nephrology follow-up if persistent renal impairment and/or proteinuria

DIET
- Total caloric intake of 20 to 30 kcal/kg/day (1)
- Restrict Na+ to 2 g/day (unless hypovolemic).
- Consider K+ restriction (2 to 3 g/day) if hyperkalemic.
- If hyperphosphatemic, consider use of phosphate binders, although no evidence of benefit in AKI.
- Avoid magnesium- and aluminum-containing compounds.

PATIENT EDUCATION
Keep well-hydrated. Avoid nephrotoxic drugs, such as NSAIDs and aminoglycosides.

PROGNOSIS
- Depending on the cause, comorbid conditions, and age of patient, mortality ranges from 5% to 80%.
- In cases of prerenal and postrenal AKI, short duration of AKI correlates with good rates of
recovery. Intrarenal etiologies take longer to recover.

- Even with complete recovery from AKI, affected patients are at higher subsequent risk of developing CKD and end-stage renal disease.
- Among patients who require RRT for AKI, recovery more likely with higher baseline epidermal growth factor receptor, AKI from ATN due to sepsis or surgery; recovery less likely with preexisting heart failure (6)

COMPLICATIONS
Death, sepsis, infection, seizures, paralysis, peripheral edema, CHF, arrhythmias, uremic pericarditis, bleeding, hypotension, anemia, hyperkalemia, uremia

ADDITIONAL READING

SEE ALSO
- Chronic Kidney Disease; Glomerulonephritis, Acute; Hepatorenal Syndrome; Hyperkalemia; Prostatic Hyperplasia, Benign (BPH); Reye Syndrome; Rhabdomyolysis; Sepsis
- Algorithm: Anuria or Oliguria

CODES
ICD10
- N17.0 Acute kidney failure with tubular necrosis
- N17.1 Acute kidney failure with acute cortical necrosis
- N17.8 Other acute kidney failure

**CLINICAL PEARLS**

- Three categories of AKI:
  - Prerenal: decreased renal perfusion (often from hypovolemia) leading to a decrease in GFR; reversible
  - Intrarenal: intrinsic kidney damage; ATN most common due to ischemic/nephrotoxic injury
  - Postrenal: extrinsic/intrinsic obstruction of the urinary collection system
- Indications for emergent hemodialysis: severe hyperkalemia, metabolic acidosis, or volume overload refractory to conservative therapy; uremic pericarditis, encephalopathy, or neuropathy; and selected alcohol and drug intoxications
- Management of ATN is supportive; no specific treatments are proven to effectively hasten recovery
- Fluid management remains a mainstay of treatment in prerenal and intrinsic kidney injury.
ADENOMYOSIS
Bradley Turner, MD, MPH, MHA, FCAP, FASCP

BASICS

DESCRIPTION

- Benign invasion of the endometrium into the myometrium, producing a diffusely enlarged uterus
- Considered a specific entity in the PALM-COEIN FIGO (polyp; adenomyosis; leiomyoma; malignancy and hyperplasia; coagulopathy; ovulatory dysfunction; endometrial; iatrogenic; and not yet classified - International Federation of Gynecology and Obstetrics) classification of causes of abnormal uterine bleeding
- Microscopically, there are ectopic, nonneoplastic endometrial glands and stroma surrounded by hypertrophic and hyperplastic myometrium.
- Can be either diffuse or focal, depending on the extent of myometrial invasion
- In some cases, it may manifest as a circumscribed myometrial mass referred to as an adenomyoma.
- Most commonly affects the posterior wall of the uterus
- Typically associated with the uterus; however, the term “adenomyosis” can also be applied to benign hyperplastic changes in the bile ducts, gallbladder, and ampulla of Vater.

EPIDEMIOLOGY

- Historically, adenomyosis had been found to present more frequently in the 4th and 5th decades; however, it is increasingly being identified in younger women with pain, abnormal uterine bleeding, infertility, or no symptoms at all, by using imaging techniques such as transvaginal ultrasound (TVUS) and magnetic resonance imaging (MRI) (1,2)[B].
- Wide variation among racial and ethnic groups and among different geographic regions

Incidence

- Typically considered a uterine condition of women who are multiparous, have had prior cesarean section, or have had prior uterine surgery; however, an increasing amount of evidence suggests that there is also an association with infertility and reproductive failure.
- Variability in the criteria used for diagnosis make an accurate determination of true incidence difficult.
- Depending on the criteria used for diagnosis, the incidence has been estimated as between 10% and 80%.
- The incidence has been reported to be higher in women presenting with endometriosis.

Prevalence

- As with incidence, an accurate determination of prevalence is difficult due to the variability in the criteria used for diagnosis.
- Depending on the criteria used for diagnosis, the prevalence has been reported to vary from 5% to 70%, with the mean frequency of adenomyosis at hysterectomy given as approximately 20–30%.

ETIOLOGY AND PATHOPHYSIOLOGY
Adenomyosis has been described as an abnormal ingrowth and invagination of the basal endometrium into the inner layer of the myometrium (junctional zone [JZ]).

The exact mechanism regarding how this occurs and is maintained is not clear and likely to be multifactorial.

Two main theories predominate to explain the origin and pathogenesis of adenomyosis:

- Dysregulated tissue injury and repair promoting cell migration and invagination of the endometrial basalis into the myometrium (1)[B]
- De novo epithelial-mesenchymal transition among displaced embryonic Müllerian remnants or adult stem cells (1)[B]

Molecular alterations in eutopic endometrium seem to contribute to migration and survival of ectopic endometrial implants beyond the myometrial interface.

Sex steroid hormone aberrations, inflammation, altered cell proliferation, and neuroangiogenesis are likely key pathogenic mechanisms of pain, bleeding, and infertility in adenomyosis.

In women with adenomyosis, the JZ may represent a region of morphologic dysfunction and structural weakness, with varying susceptibility to invagination of endometrial stromal cells.

Increased uterine pressure associated with pregnancy, leiomyomas, or other pathology may modulate the JZ environment, making it more susceptible to invagination of endometrial stromal cells.

**Genetics**

- DNA microarray and proteomics analysis have identified specific genes that are differentially expressed in adenomyosis and matched eutopic endometrium.
- Data suggest that genetic and epigenetic abnormalities contribute to the pathogenesis of adenomyosis.

**RISK FACTORS**

- Age >40 years; however, the disease has been increasing identified in women of younger age, including adolescents. Reports suggest that early-stage adenomyosis might present a different clinical phenotype compared to late-stage disease.
- Multiparity
- Tamoxifen treatment
- Other possible risk factors:
  - Infertility and reproductive failure (growing body of literature)
  - Previous uterine surgery (studies have been inconsistent)
  - Smoking (studies have been inconsistent)

**COMMONLY ASSOCIATED CONDITIONS**

- Leiomyomas (uterine fibroids)
- Endometriosis
- Endometrial polyps
- Urinary tract dysfunction

**DIAGNOSIS**

Pelvic pain, dysmenorrhea, and an enlarged uterus are the usual cues that prompt imaging by ultrasound or MRI; endometrial or uterine biopsies may be indicated in some cases.
HISTORY
- Presenting symptoms are nonspecific and one third of patients with adenomyosis are asymptomatic [2][B].
- Symptoms often include the following:
  - Menorrhagia
  - Dysmenorrhea
  - Chronic pelvic pain
  - Abnormal uterine bleeding
- Urinary tract symptoms (e.g., stress urinary incontinence, urgency, daytime frequency, and urge urinary incontinence) have been associated with an increased incidence of adenomyosis; however, data are limited.

PHYSICAL EXAM
Uterus may be enlarged and tender.

DIFFERENTIAL DIAGNOSIS
- Pregnancy
- Benign uterine tumors
- Malignant uterine tumors
- Metastatic disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- A shared histological and radiologic classification system defining the type and severity of adenomyosis has not been developed.
- A standard radiologic classification system defining the type and severity of adenomyosis has also not been developed.
- Recently, a uniform standardized reporting system of ultrasound findings of adenomyosis was developed by using the Morphological Uterus Sonographic Assessment (MUSA) criteria [3][A].
- TVUS is the imaging method of choice for initial evaluation of suspected adenomyosis [2,4][A].
- TVUS can be either two or three dimensional [2,4][A].
- Three-dimensional TVUS can provide JZ thickness [1][B].
- TVUS has a sensitivity of 65–81% and a specificity of 65–100% [1,2][A], with two-dimensional TVUS being slightly less sensitive and slightly more specific.
- TVUS is less sensitive than MRI in differentiating adenomyosis from leiomyoma [5][A].
- MRI has a pooled sensitivity of 77%, specificity of 89%, positive likelihood ratio of 6.5, and negative likelihood ratio of 0.2 for all subtypes, showing better results compared with those of TVUS [5][A].
- Leiomyomas are associated with adenomyosis in 36–50% of cases, making MRI an ideal imaging method [1][A].
- MRI should be considered when TVUS cannot provide a definitive diagnosis.

Diagnostic Procedures/Other
- Uterine biopsy with histologic interpretation
- Uterine-sparing operative treatment (USOT) with histologic interpretation
Test Interpretation

- The two-dimensional sonographic markers of adenomyosis include the following (1)[A]:
  - Uterine enlargement (with no visualized leiomyoma)
  - Cysts
  - Hyperechoic islands
  - Asymmetrical uterine wall thickening
  - Subendometrial echogenic linear striations
  - Translesional vascularity
  - Fan-shaped shadowing
  - Irregular and/or thickened JZ
  - Interrupted JZ

- Although several criteria have been proposed, a JZ thickness exceeding 12 mm seems to be highly predictive of adenomyosis (2)[B].

- Features of adenomyosis on MRI include low-intensity widening of the JZ on T2-weighted images, which corresponds to smooth muscle hyperplasia and thickening of the JZ (2)[A].

- Three objective parameters have been identified for an MRI diagnosis of adenomyosis:
  - Thickening of the JZ to at least 8 to 12 mm (2)[B]
  - JZ max/total myometrium >40% (2)[B]
  - JZ max–JZ min >5 mm (2)[B]

- Histologic interpretation has traditionally been considered the most practicable way to establish a definitive diagnosis of adenomyosis (1,2)[C].

- Pathologic interpretation of uterine biopsy:
  - Presence of endometrial glands and stromal elements within the myometrium
  - Often difficult to definitively diagnose adenomyosis on smaller samples due to sampling bias and/or biopsy artifact.

- Pathologic interpretation of uterine-sparing operative treatment and hysterectomy:
  - In morcellated specimens, diagnostic difficulty arises due to modification of the spatial arrangement of the tissue, leading to difficulty in referencing the surface. Sampling bias can also be an issue (1)[A].
  - Even in cases where the surface is accurately referenced, criteria vary among pathologists regarding the depth of invasion, which “definitively” defines adenomyosis (2)[A].

**TREATMENT**

- There are no international guidelines to follow for medical or surgical treatment of adenomyosis.
- The mainstay of treatment has been surgical therapy.
- Medical therapy shows promise in certain patients.

**MEDICATION**

- Continuous use of oral contraceptive pills, high-dose progestins, and selective progesterone receptor modulators can temporarily improve the symptoms.
- Use of a levonorgestrel-releasing intrauterine device is also an effective, reversible, and long-term treatment used successfully to treat adenomyosis (1,2)[A].
ADDITIONAL THERAPIES
Selective progesterone receptor modulators, aromatase inhibitors, valproic acid, and antiplatelet therapy are under development for the treatment of adenomyosis (1,2)[C].

SURGERY/OTHER PROCEDURES
- Hysterectomy is curative.
- Uterine-sparing operative treatment (USOT) might be considered for women who wish to preserve fertility or do not wish to have a hysterectomy.
  
  **USOT excisional** techniques (1)[B]:
  - Complete excision (adenomyomectomy)
  - Cytoreduction (partial adenomyomectomy)

  **USOT nonexcisional** techniques (1)[B]:
  - Laparoscopic techniques including electrocoagulation and uterine artery ligation
  - Hysteroscopic techniques including endometrial ablation, endomyometrial resection
  - MRI or ultrasound-guided high-frequency ultrasound ablation (high-intensity focused ultrasound [HIFU])
  - Uterine artery embolization
  - Other reported techniques include the following:
    - Alcohol instillation (cystic adenomyosis)
    - Radiofrequency ablation (focal adenomyosis)
    - Microwave ablation
    - Thermoablation (diffuse adenomyosis)

- Of the nonexcisional techniques, HIFU and uterine artery embolization (UAE) seem to offer the most encouraging results (1)[C].

  A systemic review of USOT for adenomyosis in reproductive-aged women suggests that USOT may possibly improve fertility, although the best method of surgery is yet to be seen (6) [A].

ONGOING CARE

PATIENT EDUCATION
https://www.mayoclinic.org/diseases-conditions/adenomyosis/symptoms-causes/syc-20369138

PROGNOSIS
- Adenomyosis is a benign proliferation of endometrial tissue.
- Symptoms usually resolve after menopause.
- Hysterectomy is curative.
- Additional studies are still needed to determine the impact of untreated adenomyosis and USOT on fertility and reproductive outcomes.
- Additional studies are still needed to clarify the role of medical treatment in women with adenomyosis.
- A consensus on the criterion for diagnosing adenomyosis needs to be reached.

COMPLICATIONS
- Anemia from blood loss associated with heavy periods.
- Patients with adenomyosis have been reported to be at increased risk for malignant disease;
however, to date, there has not been sufficient morphologic, genetic, or epigenetic evidence to substantiate the malignant transformation of adenomyosis.

REFERENCES

ADDITIONAL READING

CODES

ICD10

N80.0 Endometriosis of uterus
CLINICAL PEARLS

- Adenomyosis is often asymptomatic.
- MRI is more sensitive than TVUS, particularly in differentiating adenomyosis from leiomyoma. Differentiation of adenomyosis from leiomyoma is critical because the former is often treated with hysterectomy, whereas the latter is often treated with uterine conservation.
- Histological diagnosis is the gold standard.
- Various medical and surgical therapeutic options, including uterine-sparing operative techniques, are available for adenomyosis.
- Hysterectomy is curative.
- There is no shared histological and radiologic classification of adenomyotic lesions.
- A uniform and shared reporting system needs to be implemented in order to improve our understanding on imaging features, their relationship with pathogenic theories, and their importance in terms of clinical symptoms and response to treatment.
ADHESIVE CAPSULITIS (FROZEN SHOULDER)
Berenice Subero Pablo, MD • Cassandra Shipp, MD • George G.A. Pujalte, MD, FACSM

**BASICS**

**DESCRIPTION**
- Frozen shoulder or adhesive capsulitis (AC):
  - Presents as progressive painful restriction in range of movement of the glenohumeral (GH) joint (1)
  - Resolution ranges from complete to varying degrees of limitation for active and passive shoulder movements (1).
  - Unlike early disease (typically painful), late AC can present as pain-free restricted motion.
- Subtypes:
  - Primary AC:
    - Idiopathic
    - Usually associated with diabetes mellitus (DM) (1)
    - Typically resolves in 9 to 18 months (2)
  - Secondary AC:
    - Typically due to prolonged immobilization
    - Most commonly as complication of rotator cuff impingement syndrome (rotator cuff tendonitis) that remains incompletely treated
    - Sometimes called “shoulder-hand-syndrome” which is a complex regional pain syndrome (or reflex sympathetic dystrophy), if it is characterized by shoulder pain, diffuse swelling, and decreased range of motion (ROM) (2)
- Clinical course:
  - Phase 1 (2 to 9 months): painful phase. Pain is constant. Diagnosis may be difficult if restricted movement is not present in early disease.
  - Phase 2 (4 to 12 months): stiffening or freezing phase. Movement becomes restricted, especially during external rotation.
  - Phase 3 (12 to 42 months): resolution or thawing phase; gradual return to normal shoulder mobility (2)

**EPIDEMIOLOGY**
- Incidence: 2.4/1,000 people per year (2)
- Prevalence: 2–5% in the general population, 10–20% among diabetics (2)

**ETIOLOGY AND PATHOPHYSIOLOGY**
Underlying fundamental processes:
- Idiopathic
- Inflammation: Mast cells, T cells, B cells, and macrophages have been identified histologically, suggesting an inflammatory process.
- Angiogenesis
- Scarring: Fibroblasts and myofibroblasts have been identified histologically. Capsular contracture reduces the joint volume to 3 to 4 mL compared to the normal 10 to 15 mL.
Genetics
No predisposition identified

RISK FACTORS
- Shoulder immobilization; often due to impingement syndrome (most significant risk factor)
- Increasing age (1)
- Female gender (1)
- Diabetes (1)
- Thyroid disease (1)
- Atherosclerotic cardiovascular disease (ASCVD): cerebrovascular accident (CVA)/myocardial infarction (MI)/hyperlipidemia (2)
- Antiretroviral medication use
- Parkinson disease
- Trauma/surgery (1)
- Prior history of AC in contralateral shoulder

GENERAL PREVENTION
- Active lifestyle, while avoiding shoulder injury
- Control of diabetes, atherosclerotic disease, thyroid, and autoimmune conditions

COMMONLY ASSOCIATED CONDITIONS
DM, autoimmune disorders, Parkinson disease, highly active antiretroviral therapy (HAART) use, CVA/MI, cervical disc disease, hyperthyroidism (1)

DIAGNOSIS

HISTORY
- Identify possible risk factors.
- Progressive and worsening stiffness of the GH joint
- Majority will have diffuse shoulder pain, especially at the beginning of the disease.
- On the late phase of the disease, stiffness becomes predominant.

PHYSICAL EXAM
- Limitation in both active and passive ROM
- Capsular pattern of restriction is demonstrated, with external rotation most affected, followed by abduction, and then flexion (1).
- Pain with rotator cuff impingement tests
- Inability to reach overhead or back pocket
- Scapular substitution frequently accompanies active shoulder movement.
- Injection test can be helpful in differentiating AC from subacromial pathologies such as rotator cuff tendinopathy (which should improve with injection of local anesthetics, in contrast to AC). This should only be done if the diagnosis is still uncertain after a thorough history and physical.

DIFFERENTIAL DIAGNOSIS
- Rotator cuff strain/tear/impingement syndrome
- GH or acromioclavicular joint osteoarthritis (OA)
• Cervical strain/radiculopathy/OA
• Subacromial bursitis
• Parsonage-Turner syndrome: brachial plexus inflammation secondary to a trigger, such as an infection, trauma, or autoimmune condition
• Myofascial pain syndrome
• Calcific tendonitis
• Fracture
• Shoulder subluxation/dislocation
• Bony neoplasm/metastasis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• No labs are required for idiopathic AC. Blood tests can be used to check for associated/related conditions, such as diabetes, thyroid disease, a stroke, autoimmune diseases, and, in rare cases, Parkinson disease (e.g., thyroid-stimulating hormone, hemoglobin A1C, erythrocyte sedimentation rate).
• Imaging
  – Plain radiographs of the affected shoulder (posteroanterior, external rotation, axillary, and supraspinatus outlet views)
    o Preferred initial tests
    o In most cases, will be negative
    o Used primarily to rule out other pathologies such as GH OA, fractures, dislocation, or tumors (2)
  – Magnetic resonance imaging (MRI)
    o Not indicated unless there is a concomitant pathology in the shoulder or neurologic deficit
    o May show thickening of the joint capsule and the coracohumeral ligament along with edema and increased joint fluid (2)
  – Ultrasound (US)
    o Indications similar to those for MRI
    o Selection depends on individual cases and clinician’s preference.
    o Can also reveal joint capsule thickening and increased joint fluid
    o Doppler can show increased vascularity around the intra-articular portion of the biceps tendon and coracohumeral ligament.

TREATMENT
• In most cases, self-limited
• Manage patient expectations; resolution often takes 18 months of medication and rehabilitation (2).

MEDICATION
• Pain management
  – Acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs) are first line of treatment.
• Glucocorticoid injections:
  – Can be beneficial especially when administered at the beginning of the disease
– A short course of physical therapy after an injection, for 4 to 6 weeks, can improve pain and ROM (3).
– Injection may be diluted with a local anesthetic like lidocaine. Triamcinolone 20 to 40 mg or methylprednisolone 20 to 40 mg can be used.

ADDITIONAL THERAPIES
- Exercise and physical therapy:
  – Gentle ROM exercises should be offered to every patient.
  – Exercises should be performed daily and as tolerated. A structured plan should be given to the patient (4).
  – Physical therapy has been found to be beneficial especially in phases 2 and 3 of AC. Best data supports its use in conjunction with other treatment, like corticosteroids (5).
- Laser has been suggested as a possible treatment, particularly for pain relief; not enough evidence for support

SURGERY/OTHER PROCEDURES
- Should be reserved for patients who do not respond to conservative measures for at least 1 year
- Some of the most common procedures include manipulation under anesthesia, arthroscopic capsular release, distension arthrogram, among others (2).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- After establishing a diagnosis, assess the need for pain control and start the patient on NSAIDs, in combination with a gentle exercise program.
- Follow up in 3 to 4 weeks: if no significant improvement, may consider intra-articular corticosteroid injections (5)
- Physical therapy should also be considered because it can hasten the rate of recovery and increase ROM (5).
- For secondary AC, consider evaluation by a multidisciplinary team.
- If no improvement, consider surgical intervention (2).

PATIENT EDUCATION
- Patient education is important; explain prognosis and ensure compliance with treatment.
- Climbing the wall: Face a wall and place the hand from the affected shoulder flat on the surface of the wall; use the fingers to “climb” the wall; pause 30 seconds every few inches. Repeat the exercise after turning the torso 90 degrees to wall (abduction).
- In case of secondary AC, address the importance of treating underlying causes.

PROGNOSIS
- Recovery is dependent on onset of treatment, symptoms, and comorbidities in patient.
- Variable duration, lasting 1 to 3 years without intervention (1)
- Patients with idiopathic frozen shoulder have a good rate of recovery (6).

REFERENCES
1. Zreik NH, Malik RA, Charalambous CP. Adhesive capsulitis of the shoulder and diabetes: a

CODES

ICD10
- M75.00 Adhesive capsulitis of unspecified shoulder
- M75.01 Adhesive capsulitis of right shoulder
- M75.02 Adhesive capsulitis of left shoulder

CLINICAL PEARLS
- Frozen shoulder or AC is generally a self-limiting global restriction in ROM of the shoulder joint. Up to 50% will have permanent inability to externally rotate the shoulder.
- Natural course consists of a painful phase, freezing phase, and thawing phase. It occurs mostly in older women; total prevalence is 2–5% of the general population and roughly 10–20% of the diabetic population.
- Most common physical exam finding is diminished ability to externally rotate the shoulder. Other signs include pain on provocation of subacromial space and inability to reach overhead or for back pocket.
- Plain x-rays are the preferred initial imaging modality. MRI and US are done only if there is concomitant pathology or neurologic deficit.
- Treatment includes pain control with NSAIDs or acetaminophen, glucocorticoid therapy (injections or short course of oral steroids), physical therapy, or surgery.
- Resolution of symptoms often takes 18 or more months.
ADOPTION, INTERNATIONAL
R. Aaron Lambert, MD, FAAFP

BASICS

DESCRIPTION
• Although international adoptions have decreased in the past 15 years, they still represent a significant portion of ~135,000 yearly U.S. adoptions.
• Diverse birth countries, disease exposures, and unknown health histories make them particularly complex.
• Multidisciplinary teams are often necessary for appropriate care. Many adoptive parents seek advice regarding adoption health needs from their primary care provider.

EPIDEMIOLOGY
Incidence
• 4,058 children were adopted internationally in 2018. This number has decreased every year since 2004.
• 5% of current U.S. adoptions are international.
• In 2018, the most common countries of origin for internationally adopted children were China (~40%), India, Ukraine, Colombia, South Korea, Nigeria, and Ethiopia.
• In 2018, 52% of internationally adopted children were <5 years, 33% were ages 5 to 12 years, and 15% were 13 to 17 years. More females than males were adopted internationally (52% vs. 48%) (1).

RISK FACTORS
• Unknown birth, medical, and vaccination histories
• Possible in utero or postnatal toxin exposure
• Inadequate nutrition (before or after birth)
• Exposures to infectious diseases not commonly seen in the United States (2)
• Overcrowded or institutionalized living situations (e.g., orphanages)
• History of neglect, deprivation, or abuse
• Potential risks associated with foreign travel for the adopting family (3)

GENERAL PREVENTION
• A State Department–approved physician must examine the child in their native country (“panel evaluation”) before immigration to the United States. This is a limited examination targeted at identifying diseases excluding visa qualification.
• Children should be examined by a physician within 2 weeks of arrival in the United States (3).
• A follow-up visit 4 to 6 weeks after their postadoption appointment is also recommended.
• Screen for hearing, vision, growth, and developmental delay.
• Review immunization record (if available).
• A travel medicine visit is encouraged for family members who are traveling to the adopted child’s country of origin (3).
• A preadoption visit can help clarify medical diagnoses; review available medical records (including photos and/or video) to confirm/refute specific diagnoses (2).
COMMONLY ASSOCIATED CONDITIONS

- 80% of international adoptees have medical or developmental issues, 20% of these are severe (4).
- Infectious diseases:
  - Hepatitis A/B/C
  - Intestinal parasites
  - Tuberculosis (TB), primarily latent
  - Syphilis, including inadequately treated
  - HIV
  - Helicobacter pylori
- Emotional or behavioral problems
- Developmental delay
- Fetal alcohol syndrome
- Feeding difficulties, malnutrition, rickets
- Anemia
- Congenital anomalies (e.g., cleft lip/palate, orthopedic deformities)
- Prematurity or low birth weight
- Inadequate immunizations
- Lead poisoning
- Sensorineural and conductive hearing loss
- Strabismus, blindness

DIAGNOSIS

HISTORY

- Medical records are often limited or difficult to access.
- Review immunization records carefully. Records that are “too perfect” should raise suspicion.
  - Some vaccinations (e.g., Haemophilus influenzae type B [Hib], pneumococcal, varicella) are not routine in other countries.
- Review birth/prenatal history, including exposures.
- Review available family history.
- Review documented history of emotional or nutritional deprivation and physical or sexual abuse.
- Review time (if any) spent in orphanage or other institution.
- Growth charts are critical—review carefully. The first sign of malnutrition is failure to gain weight, followed by slowed linear growth, and a lag in head circumference.
- Review or observe (as able) data regarding developmental milestones, behavior, attachment, parent stress, and parent–child interactions.

PHYSICAL EXAM

- This may be the child’s first comprehensive exam; be sensitive to cues the child is providing and use a translator as necessary.
- Comprehensive physical exam. Highlight:
  - Growth parameters
  - General appearance; presence of features suggestive of genetic disorder, syndromes, or congenital defects
– Skin—infection or signs of prior abuse (4)
– Genitalia—signs of abuse or ritual cutting
– Neurologic—sensorimotor skills, coordination, reflexes
– Oral exam—tooth development and signs of decay
– Abdomen—hepatosplenomegaly

Assess development using a validated instrument; the date of birth may be unknown (2).
Assess development at each visit to identify delay and potential need for additional services.
About 50–90% of internationally adopted children are delayed on adoption; most have normal
cognition at long-term follow-up.

**DIAGNOSTIC TESTS & INTERPRETATION**

- Developmental screening
- Hearing and vision screening

**Initial Tests (lab, imaging)**

- Based on history and physical exam (2)[C],(3,5)[A]:
  - Hepatitis A (Hep A IgM, Hep A IgG)
  - Hepatitis B (HBsAg, HBsAb, HBcAb)
  - Hepatitis C (enzyme immunoassay [EIA])
  - HIV 1 and 2 antibody testing/ELISA
  - Syphilis: nontreponemal (RPR, VDRL, or ART) and treponemal (MHA-TP, FTA-ABS, or
    TPPA)
  - Tuberculin skin test (TST) in all ages or interferon-γ release assay ages ≥5 years
  - Three stool specimens for ova and parasites, specific request for Giardia intestinalis and
    Cryptosporidium species testing of one sample
  - Complete blood count (CBC) with indices and differential
  - Blood lead concentration for ages ≤6 years
  - Thyroid-stimulating hormone (TSH)
  - Urinalysis
  - Hemoglobinopathy/blood disorder screen—sickle cell, thalassemia, glucose-6-phosphate
    dehydrogenase (G6PD) deficiency

- Consider:
  - Antibody titers depending on veracity of immunization records (6)[C]
  - Stool cultures for bacterial pathogens (diarrhea) (2)[C]
  - H. pylori testing (dyspepsia, abdominal pain, or anemia)
  - Ca++, PO4, alkaline phosphate, and 25-hydroxyvitamin D level (rickets) (2)[C]
  - >12 months of age: for Chagas disease via Trypanosoma cruzi, serologic testing in adoptees
    from endemic countries (Mexico, Central and South America)
  - >24 months of age: Review CBC for eosinophilia to consider lymphatic filariasis in
    children from sub-Saharan Africa, Egypt, Southern Asia, Western Pacific Islands, the NE
    coast of Brazil, Guyana, Haiti, and the Dominican Republic (5)[A].

**Follow-Up Tests & Special Considerations**

**ALERT**
If initially negative, repeat HIV, Hep B, Hep C, and TB testing is recommended at 6 months;
negative tests may represent a “window” period or be falsely negative due to malnutrition (in the
- HIV: Confirm antibody positive in children <18 months with DNA polymerase chain reaction (PCR) (may represent maternal antibody) [3][A].
- Hep C: Confirm positive tests with recombinant immunoblot assay (RIBA) and/or hepatitis C virus RNA PCR; an initial positive in children <18 months may be due to maternal antibody, repeat after 18 months of age.
- Positive TST (TB): Do not attribute to bacillus Calmette-Guérin (BCG) vaccine. Evaluate for active disease; treat latent TB infection (LTBI).
- Test for intestinal parasites if gastrointestinal symptoms persist.
- Eosinophilia >450 cells/mm³ with negative stool ova and parasites: serologic testing for Schistosoma; add Strongyloides for adoptees from sub-Saharan African, Latin American, and Southeast Asian countries [2][C].
- Behavioral concerns may first present during adolescence, even for children adopted in infancy.
- For children with history of treated congenital syphilis, follow with ophthalmologic, audiologic, neurologic, and developmental screening.

**TREATMENT**

**GENERAL MEASURES**
- Regular diet for children who arrive malnourished
- Monitor linear growth.
- Consider early intervention for children with suspected delays.
- Involve parents in local and online support groups.
- Postadoption depression may occur in parents.

**MEDICATION**
- Immunizations: Catch up vaccines per Centers for Disease Control and Prevention (CDC) schedule (http://www.cdc.gov/vaccines/schedules/).
  - No further Hep B vaccine if HBsAg positive, HBsAb and HBcAb positive, or HBsAb positive and HBV vaccine given appropriately
  - Measles, mumps, and rubella (MMR) vaccination for mumps and rubella, even if measles antibodies present [6][C]
- Possible approaches [5][A]:
  - Repeating questionable vaccinations negates the need to obtain serologic tests.
  - To minimize/avoid vaccine administration, check antibody titers—infants 6 to 12 months: polio; diphtheria; children >1 year: Hep A; MMR; varicella [6][C]
- Ensure adoptive parents, caretakers, and household members are up-to-date with tetanus, diphtheria, and pertussis, Hep A/B, and measles vaccines [3][A],[4][C].

**ISSUES FOR REFERRAL**
- Time referrals and elective procedures to allow adjustment to new home [2][C]
- Individual and/or family counseling does help adjustment.
- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head banging) related to prior sensory deprivation. These behaviors typically decrease with time,
and no treatment is necessary if the child is otherwise developing normally. If in doubt, refer
to developmental pediatrics or occupational therapy.
– If a child continues to have disruptive behaviors, or would rather self-soothe than seek
nurturing human interaction, consider intervention.
– Persistent behavioral issues in the parent–child interactions merit further evaluation.
• Refer to pediatric ophthalmology for strabismus (seen in 10–25% of previously
institutionalized adoptees).
• Refer to audiology and/or ear/nose/throat for concerns, questionable screening results, or if
slow to acquire language skills.
• No longer hearing one’s native language slows speech development. Speech therapy helps
children from non–English-speaking countries.
• Pediatric dental evaluation by 12 months of age; sooner if signs of dental pathology is present

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Regular well-child visits, particularly within first months of entry into the United States
• Close monitoring of developmental milestones, behavior, and attachment

DIET
• Regular diet, with specific attention to known nutritional deficiencies within country of origin
(http://adoptionnutrition.org)
• Up to 68% of international adoptees fall >2 standard deviations below the mean for one or
more growth parameters; most begin to follow an appropriate growth curve (<2 deviations
from the mean) within 9 to 12 months of arrival to the United States.

PATIENT EDUCATION
• Allow ad lib access to healthy foods to promote self-regulatory eating behaviors.
• Toileting: Some children may not be trained yet; others may regress in their new home. Time,
positive reinforcement, and avoiding punishment often resolve this issue as the child adjusts to
new surroundings.
• Sleeping: Children must learn to trust their new home and parents. Avoid aggressive sleep
rules. Parents should be present physically and emotionally to establish safety and promote
bedtime ritual.
• Language: Adoptive family should learn key phrases in the child’s native language prior to
adoption. When using translator services, be careful to avoid perception of translator use
equating to potential return to native country.
• Adopted children may grieve lost family, relationships, and culture; encourage parents to
acknowledge this and openly work through it. Provide counseling if needed.
• Encourage families to learn about the child’s culture and ethnicity of origin (4).

PROGNOSIS
• Recovery from developmental delay correlates with time spent in institutional setting.
  – Risk of long-term developmental, behavioral, or academic problems increases with adoption
age.
- Rate of recovery exceeds rate of normal development (3).
- Children may regress in previously acquired skills (2).
- A desire to search for biologic family is common in adolescence (4).

- Z62.821 Parent-adopted child conflict

CLINICAL PEARLS
- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head
  banging) that usually decrease over time. Refer to developmental or occupational specialist
  when concerns persist.
- A preadoption visit can identify medical concerns, ensure travel safety for prospective parents,
  and prepare resources prior to a child’s arrival.
- Initial labs for internationally adopted children include Hep A/B/C, HIV 1/2, CBC, TSH, lead,
G6PD deficiency, hemoglobin electrophoresis, PPD/TST (or IGRA ages ≥5 years), ova and parasites (three stool specimens, including single specimen for Giardia and Crypto
apsidium antigens), and urinalysis.

- If initially negative, repeat HIV, Hep B/C, and TST at 6 months.
- Catch up immunizations per CDC schedule (http://www.cdc.gov/vaccines/schedules/).
- Ensure that appropriate immunizations are up-to-date for adoptive family and caretakers.
BASICS

DESCRIPTION

- Advance care planning (ACP) allows patients to have a voice in the decisions that affect their care after they lose the ability to do so for themselves.
- There are several methods of addressing goals of care as patients age:
  - Advance directives, including living wills (LWs) and health care durable powers of attorney (DPOAs)
  - Physician/medical orders for life-sustaining treatment (POLST/MOLST)
  - Facilitated conversations with family and significant others
- ACP is an important aspect of patient-centered care as the population ages and individuals lose decision-making capacity or when new chronic medical conditions are diagnosed.
- It can be challenging to interpret patient wishes in the context of individual illness circumstances, negotiate conflicts in decisions, and to help patients determine what is in their best interest based on personal values.
- Definitions
  - Advance directives (1): written instructions to guide decision making in the event a patient is unable to provide informed consent
    - LWs and DPOAs usually only take effect if the patient has been determined to lack capacity to decide care for him or herself; otherwise, patient preference takes precedence (even if contradictory to a LW).
    - Done appropriately, these can help patients avoid languishing in poor quality of life states and complicated ethical dilemmas.
  - LW: a patient’s explicit written instructions of his or her wishes regarding medical care
    - Each state has specific legal requirements. Certain states do not recognize LWs but have other “medical directive” forms. LWs and medical directives can take effect immediately (e.g., when a patient is diagnosed with a terminal illness) or when a patient can no longer make decisions for him or herself.
    - LWs have direct treatment instructions.
    - Challenges of LWs include lack of standardization, potential completion too far in advance of use, and narrow scope.
    - LWs do not expire, but they can be revised.
    - The LW is a documentation of patient preferences and may not prevent life-sustaining treatment in an emergent situation (as a POLST can [see below]).
  - DPOA: a written document designating a surrogate decision maker in the event a patient cannot speak for him or herself
    - A health care proxy (HCP) speaks on behalf of the patient to make decisions aligned as closely as possible to the patient’s wishes. Ideally, this is someone the patient knows and trusts. It is also helpful if this individual has had discussions with the patient about his or her values and desires.
    - If multiple HCPs are named, disagreements about who speaks for the patient must be resolved before a decision can be made.
If there is a conflict between an LW provision and an HCP decision, different states have varying rules regarding precedence. In some states, the DPOA supersedes the LW; in other states, the most recently executed document is legally binding.

If a patient has had goals of care discussions with friends or family but does not have a legally named HCP, those discussions can still help inform the decision-making process.

- POLST/MOLST: a medical directive which directs point of care decision making by emergency medical services (EMS) for patients at the end of life
  - Designed to minimize confusion in emergent situations, these are adjunctive documents to LWs and DPOAs that provide clear instruction regarding resuscitation, intubation, and other life-saving treatments.
  - They are portable and follow a patient across different care settings. Given their simplicity, a POLST/MOLST is more likely to be followed than a LW, which can be difficult to locate.
  - Although EMS may be concerned about the legal implications of withholding life-sustaining treatment, POLST forms provide legal protection if patient wishes are followed.
  - Patients with POLST documents have fewer unwanted interventions.

- Nursing home residents and patients with dementia often do not have capacity to complete legal documents related to LW and DPOA.
- ACP should be completed while patients are able to make decisions about their future care.
- There are no guidelines for when to initiate discussions about ACP; age 65 years may be an appropriate time for a realistic conversation prior to the onset of dementia or other incapacitating illness. Each conversation must be individualized.

**Pediatric Considerations**

- Pediatric ACP (pACP) is less common.
- For children with serious acute or terminal illness, it is a difficult (but important) part of treatment.
  - Provider fears about increasing parental distress when discussing pACP are unfounded.
  - pACP may unburden parents from difficult decisions and is associated with increased positive emotions, understanding of the patient’s illness, and provider rapport.

**TREATMENT**

- Suggested discussion points:
  - All adult patients:
    - Discuss basic medical decision making.
    - Assess willingness to engage in ACP. Do not force patients if they are not ready to have this potentially emotionally charged conversation.
    - Ask patients to identify who they would like to make decisions for them if they were unable to do so.
    - Encourage patients to inform trusted family or friends about new diagnoses or changes in health.
    - Discuss what values are most important to patients.
    - Document decisions concisely and clearly.
  - Any patient with a chronic or terminal illness:
Discuss the natural course of disease progression, including time course and end-of-life expectations.

For example:

- Chronic obstructive lung disease: exacerbations, decreased ability to perform activities of daily living, supplemental oxygen, mechanical ventilation
- Diabetes: macrovascular and microvascular complications (heart attack, stroke, dementia, dialysis, amputations)
- Malignancy: possibility of chronic pain, inability to swallow/poor appetite necessitating alternative feeding options, ascites and therapeutic procedures, treatment side effects

- “Elderly patients”:

  - Consider routine discussions of ACP around age 65 years. It is crucial to speak with patients while they still have decision-making capacity. Discussions should be repeated regularly to ensure patient preferences have not changed.
  - Refer patients to legal services for AD/DPOA.
  - Complete POLST forms in clinic.
  - Any change in clinical status (including frequent ER visits or hospitalizations):
    - Changes in functional status should prompt a discussion about prognosis and future wishes. Hospitalizations are important milestones to discuss recovery or decline.
    - Consider palliative care services.
    - Consider support services to prevent caregiver burnout.

At the end of life, if it is the patient’s desire, it is important to engage hospice services in a timely manner.

ACP discussions are often complicated by social, familial, cultural, and medical factors. It is important to be sensitive to each patient’s individual context.

- African Americans are less likely than whites to complete AD.
- Preference for life-sustaining treatment, religious beliefs, and mistrust of the medical community contribute to this difference.
- Do not force the conversation if a patient is resistant or unprepared to discuss ACP.
- Motivational interviewing can be used to gauge interest and readiness to discuss ACP.
- Addressing implications for friends and family who may be burdened with decision making may help promote ACP conversations.
- The first time ACP is brought up often serves as an introduction to the topic and an opportunity for the patient to consider options. Subsequent visits can address specific scenarios and choices (2).
- Avoid medical jargon (e.g., CPR, mechanical ventilation, parenteral nutrition) when addressing options. Patients may not understand the severity of illness or the implications of advanced life-saving interventions.

**ONGOING CARE**

Reimbursement: The Centers for Medicare & Medicaid Services reimburses physicians for ACP discussions.

- Current CPT codes are 99497 for the first 30 minutes of discussion and completion of forms and 99498 for each additional 30 minutes (3).
- There are no limits to the number of times ACP can be reported in a given period of time.
- An advance directive does not have to be completed in order to bill for services.
No specific diagnosis is required for the ACP codes.

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- There are no specific guidelines for how often a LW or DPOA discussion should be revisited after completion.
- When there is a new diagnosis or a significant change in clinical status, have the patient consider how it would affect his or her ACP decision making.
- Have patients display POLST/MOLST forms prominently for ease of visibility to EMS.

**PATIENT EDUCATION**
- See references for links: The National Hospice and Palliative Care Organization, Aging with Dignity, National Healthcare Decisions Day, and the American Bar Association have resources to help patients.
- Online platforms such as MyDirectives allow patients to specify their wishes electronically.
- DeathWise is a nonprofit organization with worksheets patients can use for the health, financial, care of body, and service components of ACP.

**COMPLICATIONS**
- Often LWs, DPOAs, and POLSTs are completed, but physicians do not have access to them. Electronic health records are a convenient place to store documents, but they may be difficult to retrieve.
  - Any ACP form should be part of the medical record with open access (if possible) to facilitate appropriate decision making.
  - Medical bracelets or other devices are often used to notify EMS of patient directives.
- Emergency rooms are vulnerable to uncertainty about what interventions patients want if they cannot communicate for themselves and guiding documents are not readily available.
  - POLST forms can help avoid confusion.
- There is often misunderstanding on the part of both doctors and patients regarding do not resuscitate (DNR) and do not intubate (DNI) orders.
  - DNR/DNI orders can be reversed or should not be honored in certain situations.
  - DNR/DNI in a person with a chronic progressive illness does not necessarily mean DNR/DNI for an acute reversible process.
  - The prognosis for successful resuscitation on a hospital ward is approximately 14%; it is 50-80% for patients undergoing surgery.

ADDITIONAL READING

CODES

ICD10

- Z71.89 Other specified counseling
- Z51.5 Encounter for palliative care
- Z66 Do not resuscitate

CLINICAL PEARLS

- ACP is an important and underutilized element of compassionate and comprehensive patient-centered care.
- The primary barriers to discussing advanced directives from the patient perspective include lack of knowledge, fear of burdening family, and a desire for physicians to initiate the discussion.
- The primary barriers to discussing advanced directives from the physician perspective include discomfort with the topic, lack of emotional support, lack of reimbursement, and lack of time to fully address the topic.
- Fewer unwanted interventions occur in the emergency room and inpatient setting when ACP is actively reviewed and wishes documented/conveyed appropriately.
AIR TRAVEL EMERGENCIES
Theodore E. Macnow, MD ● Michelle A. Georgia, DO

BASICS

DESCRIPTION
Half of physicians report helping with an in-flight medical emergency (IME). Many IMEs fall outside a practitioner’s normal scope of practice. The aircraft environment is cramped with limited medical resources. Despite these obstacles, health care workers should be prepared to render assistance in these situations.

EPIDEMIOLOGY

Incidence
- Exact incidence of IMEs is unknown
- Databases estimate incidence at 1 in 600 flights (1).
- Airline estimates are that there is an IME in 1 per 7,500 to 40,000 airline passengers totaling 250 to 1,500 daily events worldwide (2).
- The likelihood of physicians encountering an IME is increasing because of larger aircrafts, longer flights, and an aging population.
- The most common IMEs involve syncope/near syncope (32.7%), gastrointestinal (14.8%), respiratory (10.1%), and cardiovascular symptoms (7%) (2).
- In healthy passengers, vasovagal syncope represents up to 90% of IMEs.
- 5% of passengers suffer from a chronic illness and represent 2/3 of IME.
- 3% of IMEs are fatal; however, death may be underreported as it is often not declared in flight.

ETIOLOGY AND PATHOPHYSIOLOGY

Hypobaric hypoxia: Atmospheric pressure of oxygen drops from 160 mm Hg at sea level to 120 mm Hg at cruising altitude in a pressurized cabin.
- In healthy people, the arterial oxygen tension drops from 100 mm Hg to about 60 mm Hg with associated mean inflight oxygen saturations of 93% [range: 85% to 98%] (3).

ALERT
Passengers with chronic obstructive pulmonary disease (COPD) or other pulmonary disorders have a lower baseline PaO2, so the drop in oxygen tension may occur on the steep part of the hemoglobin dissociation curve and result in more significant hypoxemia.

ALERT
Passengers with unstable angina or heart failure may not be able to compensate for hypoxia.

- Gas expansion: Gases expand about 30% in flight. This can lead to a pneumothorax, wound dehiscence or perforation from bowel gas expansion, sinus pressure, and tympanic membrane rupture in children with ear infections.
- Venous thromboembolism: There is an increased risk for clotting because of prolonged sitting, hypoxic conditions, and dehydration. There is an increased risk of deep vein thromboses (DVTs) in passengers with underlying medical conditions and on longer flights.
- Stress: Travelling is mentally and physically stressful, which may lead to psychiatric
emergencies or acute coronary syndrome (ACS).

- **Insomnia**: Passengers have disrupted circadian rhythms, which may trigger seizures and contribute to medication noncompliance.
- **Turbulence**: Motion sickness is common and traumatic injury can result from falling luggage.
- **Medication noncompliance**: Forgotten or checked medications may lead to glycemic control problems, seizures, blood pressure instability, and inaccessible as-needed medications.
- **Decreased access to food and drink**: Vasovagal syncope may result from dehydration. Diabetics may suffer hypoglycemia.
- **Low air humidity**: Cabin air is less than 20% relative humidity which contributes to dehydration, epistaxis, and asthma or COPD exacerbations.
- **Viral infections**: Parainfluenza and influenza are the most common viruses communicated by proximity. The cabin air is filtered and not infectious.

**RISK FACTORS**

- **Recent surgery**: Passengers are at risk for wound dehiscence, bowel perforation, and compartment syndrome from gas expansion.
- **COPD, asthma, congestive heart failure, or coronary artery disease**: Passengers may suffer from hypoxemia and not be able to compensate appropriately.
- **Recent cast placement**: Passengers are at risk for compartment syndrome due to tissue edema.
- **Hypercoagulability**: Passengers with inherited or acquired hypercoagulable conditions, pregnancy, medications, heart disease, or recent surgery are at increased risk for DVTs.
- **Recent scuba diving**: Passengers are at risk for decompression syndromes.
- **Long flights**: The effects of hypoxia are cumulative and time-dependent.

**GENERAL PREVENTION**

General guidelines:

- Travelers should discuss scheduling medications with their doctor and bring medications and equipment onboard.
- Supplemental inflight oxygen is required for patients with a baseline PaO$_2$ < 70 mm Hg or who are unable to walk a flight of stairs or 150 feet without becoming short of breath or experiencing angina.

**Pregnancy Considerations**

Women are generally safe to fly until 36 weeks’ gestation

**Pediatric Considerations**

Travelers with children should bring liquid formulations of medication in allowed quantities on the plane. Children with asthma should have a rescue inhaler with spacer and face mask.

Specific guidelines:

- Avoid flying 10 to 14 days after surgery (varies by type of surgery)
- Casts may need to be bivalved if applied 24–48 hours before a flight
- Avoid scuba diving 24 hours before flying.
- DVT prevention (4)[C]
  - Adequately hydrate.
  - Avoid venous stasis by standing and mobilizing legs in flight.
  - Passengers with risk factors may need compression stockings, aspirin, or anticoagulation.
DIAGNOSIS

HISTORY
- Symptoms vary based on emergency; if patient is alert, gather as much history as possible.
- Ask about past medical and surgical history, medications and compliance, and allergies.
- Inquire about illicit drug or alcohol use.

PHYSICAL EXAM
- May need to obtain blood pressure by palpitation due to noise.
- Assess vital signs. Signs of dehydration; skin perfusion
- General appearance and mental status
- If stethoscope available on in-flight kit–auscultation as best as possible

ALERT
Assess for tension pneumothorax by listening for decreased lung sounds and contralateral tracheal deviation. A tension pneumothorax requires needle decompression.

DIFFERENTIAL DIAGNOSIS
- **Syncope or near-syncope:** vasovagal syncope, dehydration, hypoglycemia, intoxication, medication reaction or toxicity, ACS, arrhythmia, pulmonary thrombosis/air embolism, and hypoxia
- **Chest pain:** ACS, pulmonary embolism, pneumothorax, bronchospasm, aortic dissection, gastroesophageal reflux, musculoskeletal etiology, and anxiety
- **Shortness of breath:** COPD or asthma exacerbation, pneumonia, pulmonary thrombosis/air embolism, toxic exposure
- **Strokelike symptoms:** cerebrovascular accident, transient ischemic attack, hypoglycemia, seizure, syncope, intracranial mass, and complex migraine
- **Seizure:** seizure, syncope, hypoglycemia, eclampsia, cardiac arrest
- **Gastrointestinal illness:** motion sickness, foodborne illness, gastritis, enteritis, gastroesophageal reflux, pancreatitis, medication or substance withdrawal
- **Obstetric emergency:** preterm labor, miscarriage, eclampsia, placenta previa
- **Allergic reaction:** urticaria, anaphylaxis, dermatitis
- **Cardiac arrest:** arrhythmia, pulmonary embolism, respiratory arrest, ACS, intoxication, syncope
- **Altered mental status:** Use or withdrawal from drugs or alcohol (consider GI absorption from smuggling), hypoglycemia, panic attack, diabetic ketoacidosis, hypoxia, psychiatric emergency

DIAGNOSTIC TESTS & INTERPRETATION
- The automated external defibrillator (AED) can be used as a cardiac monitor.
- Ask other passengers for equipment (i.e., glucometer or pulse oximeter).

TREATMENT

GENERAL MEASURES
- **First aid and cardiopulmonary resuscitation (CPR):** If there is no pulse or not breathing,
start CPR, basic life support, ALS, and pediatric advanced life support as appropriate. Airline crew members are trained in first aid and CPR.

- **Ask for help:** Ask the flight crew and other passengers for equipment, medications, expertise, and lifting assistance.
- **Oxygen:** All flights have oxygen at 2 to 5 L per minute by face mask. This oxygen delivery at cruising altitude mimics conditions at sea level. Oxygen should be applied in all cases of respiratory distress, chest pain, seizures, and altered mental status.
- **Ground-based physician support:** Many airlines contract with companies that offer in-flight medical advice, interpreter services, recommendations for diversion, and sometimes telemedicine technology.
- **Request to fly at lower attitude:** Flying below 22,500 feet with cabin pressurization mimics sea level oxygen pressure. Flying lower uses more fuel and is slower so may not be optimal to reach a hospital quickly.
- **Request a diversion:** The pilot can request an expedited landing, medical services on arrival, or a closer destination. Medical emergencies that involve resuscitation, persistent abnormal vital signs, chest pain, stroke symptoms, respiratory distress, unconsciousness, obstetrics, or psychiatric emergencies should be considered for diversion.

**MEDICATION**

- All U.S. commercial aircrafts have an emergency medical kit (EMK) as well as basic first aid kits on the aircraft. The contents vary among countries, airlines, and aircrafts. Many airlines have adopted a more extensive EMK.
- The minimal contents in the EMK required by the Federal Aviation Administration are described in Table 1.

</tbody>
</table>
All aircraft are equipped with an AED.

**ALERT**
Not usually found in the EMK are glucometers, intubation equipment, advanced cardiovascular life support drugs, narcotics, naloxone, insulin, or antibiotics. Consider asking other passengers for needed medications or equipment.

**Pediatric Considerations**
EMKs do not include liquid or suppository medications. Consider crushing tablets or asking other passengers for medication or equipment. A toilet paper roll or cut soda bottle can be taped to an albuterol pump to make a spacer.

**ADDITIONAL THERAPIES**
- **Cardiac Arrest**: CPR; early defibrillation; Epinephrine 1: 10,000 q3–5 minutes, (Adults: 1 mg IV, Pediatric: 0.01 mg/kg IV); lidocaine or atropine when indicated. Recommend diversion.
- **Chest pain**: Oxygen by face mask, aspirin 325 mg PO, nitroglycerin (0.4 mg sublingually q5 to 10 minutes if systolic blood pressure > 100 mm Hg). Apply AED. Recommend diversion.
- **Asthma/COPD exacerbation**: Oxygen, albuterol 2.5 mg inhaled (repeat as needed), steroid (if available), epinephrine 1:1000, 0.3 mL IM if significant respiratory distress. Consider diversion.
- **Allergic reaction**: Diphenhydramine (PO or IV, Adult: 25 to 50 mg, Pediatric: 1 mg/kg); If anaphylaxis, epinephrine 1:1000, (Adult: 0.3 mL, Pediatric: 0.15 mL IM); NS (IV, Adults: 1L, Pediatric: 20 mL/kg); steroid (if available); divert if anaphylaxis.
- **Vasovagal syncope**: Elevate legs. If alert and oriented, offer oral liquids. Consider IV fluid bolus. Consider hypoglycemia and offer oral glucose. Monitor blood pressure. Consider diversion if remains symptomatic or has persistent abnormal vital signs.
- **Gastrointestinal**: Oral antiemetic may be available from the EMK or other passengers. If there is abdominal pain, consider diversion.
- **Tension pneumothorax**: Needle thoracostomy 4th or 5th intercostal space anterior axillary line
- **Psychiatric emergency**: Consider intoxication, hypo/hyperglycemia, and hypoxia. Attempt verbal de-escalation. Ask patient and other passengers if they have oral anxiolytics. If restraint is necessary, it should be by four passengers, one on each limb. Monitor the patient for signs of respiratory distress or ACS if restrained. Consider diversion.

**ONGOING CARE**

**PROGNOSIS**
- The Aviation Medical Assistance Act of 1998 protects volunteer in-flight physicians from malpractice. No physician has been successfully sued in the United States for volunteering care in an IME.
- When overhead paged for assistance, health care workers responded 76% of the time, physicians in 48% of cases (1).
- The correlation of the in-flight and hospital diagnosis is about 80%. 60% of IMEs improve with help from a health care provider (5).
REFERENCES

ADDITIONAL READING

CLINICAL PEARLS

- Medical emergencies on airplanes are common. Most are minor.
- Equipment and drugs on board airplanes vary widely.
- All flights are equipped with AEDs and oxygen.
- Many airlines partner with ground-based physician support to help the flight crew and volunteers in IMEs.
- Utilize passengers as a resource for information and supplies.
ALCOHOL USE DISORDER (AUD)
Gennine M. Zinner, RNCS, ANP

BASICS

DESCRIPTION
• Any pattern of alcohol use causing significant physical, mental, or social dysfunction; key features are tolerance, withdrawal, and persistent use despite problems.
• Alcohol abuse: maladaptive pattern of alcohol use manifested by one or more of the following:
  – Failure to fulfill obligations at work, school, or home
  – Recurrent use in hazardous situations
  – Recurrent alcohol-related legal problems
  – Continued use despite related social or interpersonal problems
• Alcohol dependence: maladaptive pattern of use manifested by ≥3 of the following:
  – Tolerance
  – Withdrawal
  – Using more than intended
  – Persistent desire or attempts to cut down/stop
  – Significant amount of time obtaining, using, or recovering from alcohol
  – Social, occupational, or recreational activities sacrificed for alcohol use
  – Continued use despite physical or psychological problems
• National Institute on Alcohol Abuse and Alcoholism criteria for “at-risk” drinking: men: >14 drinks a week or >4 per occasion; women: >7 drinks a week or >3 per occasion
• Women experience harmful effects at lower levels of alcohol consumption and are less likely to report problems related to drinking.
• System(s) affected: nervous, gastrointestinal (GI)
• Synonym(s): alcoholism; alcohol abuse; alcohol dependence

Geriatric Considerations
• Common and underdiagnosed in elderly; less likely to report problem; may exacerbate normal age-related cognitive deficits and disabilities
• Multiple drug interactions
• Signs and symptoms may be different or attributed to chronic medical problem or dementia.
• Common assessment tools may be inappropriate.

Pediatric Considerations
• Children of alcoholics are at increased risk for problem drinking.
• 2.5% of adolescents have alcohol use disorder (AUD); 13.4% of youth age 12 to 20 years report binge drinking in the past month; negative effect on maturation and normal brain development
• Early onset drinkers (those who start drinking before age 21 years) are 4 times more likely to develop a problem than those who begin after age 21 years.
• Depression, suicidal or disorderly behavior, family disruption, violence or destruction of property, poor school or work performance, sexual promiscuity, social immaturity, lack of interests, isolation, moodiness
Pregnancy Considerations
- Women should abstain if attempting conception and throughout pregnancy.
- 10–50% of children born to women who are heavy drinkers will have fetal alcohol syndrome.

EPIDEMIOLOGY
- Predominant age: 18 to 25 years, but all ages affected
- Predominant sex: male > female (3:1)

Prevalence
- 27% of Americans age 18 years or older reported they engaged in binge drinking in the past month; 7% reported they engaged in heavy alcohol use in the past month.
- 15 million adults (6%) age >18 years has AUD.

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial: genetic, environment, psychosocial
- Alcohol is a central nervous system depressant, facilitating γ-aminobutyric acid (GABA) inhibition and blocking N-methyl-D-aspartate receptors.

Genetics
50–60% of risk is genetic.

RISK FACTORS
- Family history
- Depression (40% with comorbid alcohol abuse)
- Anxiety disorders
- Tobacco use; other substance abuse
- Male gender; lower socioeconomic status
- Unemployment
- Poor self-esteem—seeking peer/social approval
- Family dysfunction or childhood trauma
- Posttraumatic stress disorder
- Antisocial personality disorder
- Bipolar disorder
- Eating disorders
- Criminal behavior

GENERAL PREVENTION
Counsel with family history and risk factors.

COMMONLY ASSOCIATED CONDITIONS
- Cardiomyopathy, atrial fibrillation
- Hypertension
- Peptic ulcer disease/gastritis
- Cirrhosis, fatty liver, cholelithiasis
- Hepatitis
- Diabetes mellitus
- Pancreatitis
- Malnutrition
- Upper GI malignancies
- Peripheral neuropathy, seizures
- Abuse and violence
- Trauma (falls, motor vehicle accidents [MVAs])
- Behavioral disorders (depression, bipolar, schizophrenia): >50% of patients with these disorders have a comorbid substance abuse problem.

**DIAGNOSIS**

**HISTORY**

- Thorough behavioral history
  - Anxiety, depression, insomnia
  - Psychological and social dysfunction, marital or relationship problems
  - Social isolation/withdrawal
  - Domestic violence
  - Alcohol-related legal problems
  - Repeated attempts to stop/reduce drinking
  - Loss of interest in nondrinking activities
  - Employment problems (tardiness, absenteeism, decreased productivity, interpersonal problems, frequent job loss)
  - Blackouts
  - Complaints about alcohol-related behavior
  - Frequent trauma, MVAs, emergency department visits

- Physical symptoms
  - Anorexia
  - Nausea, vomiting, abdominal pain
  - Palpitations
  - Headache
  - Impotence
  - Menstrual irregularities
  - Infertility

**PHYSICAL EXAM**

- Physical exam may be completely normal.
- General: fever, agitation, diaphoresis
- Head/eyes/ears/nose/throat: plethoric face, rhinophyma, poor oral hygiene, oropharyngeal malignancies
- Cardiovascular: hypertension, dilated cardiomyopathy, tachycardia, arrhythmias
- Respiratory: aspiration pneumonia
- GI: stigmata of chronic liver disease, peptic ulcer disease, pancreatitis, esophageal malignancies, esophageal varices
- Genitourinary: testicular atrophy
- Musculoskeletal: poorly healed fractures, myopathy, osteopenia, osteoporosis, bone marrow suppression
- Neurologic: tremors, cognitive deficits (e.g., memory impairment), peripheral neuropathy, Wernicke-Korsakoff syndrome (from severe acute deficiency of thiamine: Korsakoff psychosis is a chronic neurologic sequela of Wernicke encephalopathy)
Endocrine/metabolic: hyperlipidemias, cushingoid appearance, gynecomastia

Dermatologic: burns (e.g., cigarettes), bruises, poor hygiene, palmar erythema, spider telangiectasias, caput medusae, jaundice

Differential Diagnosis

- Other substance use disorders
- Depression, dementia
- Cerebellar ataxia; cerebrovascular accident (CVA)
- Benign essential tremor; seizure disorder
- Hypoglycemia; diabetic ketoacidosis
- Viral hepatitis

Diagnostic Tests & Interpretation

Screening

- CAGE questionnaire: (Cut down, Annoyed, Guilty, and Eye opener): >2 “yes” answers is 74–89% sensitive, 79–95% specific for AUD; less sensitive for white women, college students, elderly; not an appropriate tool for less severe forms of alcohol abuse
- Single question for unhealthy use: “How many times in the last year have you had X or more drinks in 1 day?” (X = 5 for men, 4 for women); 81.8% sensitive, 79% specific for AUDs (1)
- Alcohol Use Disorders Identification Test (AUDIT): 10 items, if >4: 70–92% sensitive, better in populations with low incidence of alcoholism: https://www.nams.sg/helpseekers/alcohol/self-assessment-tool/Pages/default.aspx

Initial Tests (lab, imaging)

- Complete blood count; liver function tests (LFTs); electrolytes; blood urea nitrogen (BUN)/creatinine; lipid panel; thiamine; folate; hepatitis A, B, and C serology
- Amylase, lipase (if GI symptoms present)
- Serum levels increased in chronic abuse:
  - Aspartate aminotransferase/alanine aminotransferase ratio >2.0
  - γ-Glutamyl transferase (GGT)
  - Carbohydrate-deficient transferrin
  - Elevated mean corpuscular volume (MCV)
  - ↑ Prothrombin time
  - Uric acid
  - ↑ Triglycerides and cholesterol (total)
- Often decreased
  - Calcium, magnesium, potassium, phosphorus
  - BUN
  - Hemoglobin, hematocrit, platelet count
  - Serum protein, albumin
  - Thiamine, folate
- Blood alcohol concentration warning levels
  - >100 mg/dL in outpatient setting
  - >150 mg/dL without obvious signs of intoxication
  - >300 mg/dL at any time
- CAT scan or magnetic resonance imaging of brain: cortical atrophy, lesions in thalamic
nucleus, and basal forebrain

- Abdominal ultrasound (US): ascites, periportal fibrosis, fatty infiltration, inflammation

**Test Interpretation**

- Liver: inflammation or fatty infiltration (alcoholic hepatitis), periportal fibrosis (Alcoholic cirrhosis occurs in only 10–20% of alcoholics.)
- Gastric mucosa: inflammation, ulceration
- Pancreas: inflammation, liquefaction necrosis
- Heart: dilated cardiomyopathy
- Immune system: decreased granulocytes
- Endocrine organs: elevated cortisol levels, testicular atrophy, decreased female hormones
- Brain: cortical atrophy, enlarged ventricles

**TREATMENT**

For management of acute withdrawal, see “Alcohol Withdrawal.”

**GENERAL MEASURES**

- Brief interventions and counseling by clinicians have proven effective for problem drinking (2) [B].
- Treat comorbid problems (sleep, anxiety, etc.), but do not prescribe medications with cross-tolerance to alcohol (benzodiazepines).
- Group programs and/or 12-step programs have benefit in helping patients accept treatment
- Consider referring patients with alcohol dependence to an addiction specialist or treatment program.

**MEDICATION**

**First Line**

- Adjuncts to withdrawal regimens:
  - Naltrexone: 50 to 100 mg/day PO or 380 mg IM once every 4 weeks; opiate antagonist reduces craving and likelihood of relapse and decreases number of heavy drinking days in recalcitrant alcohol abusers (IM route may enhance compliance and efficacy) (3),(4)[B].
  - Acamprosate (Campral): 666 mg PO TID after withdrawal completed; reduces relapse risk. If helpful, use for 1 year (3),(4)[B].
  - Topiramate (Topamax): 25 to 300 mg/day PO or divided BID; may enhance abstinence (5) [B] (off-label FDA use)
- Supplements for all
  - Thiamine: 100 mg/day (first dose IV prior to glucose to avoid Wernicke encephalopathy)
  - Folic acid: 1 mg/day
  - Multivitamin: daily
- Contraindications
  - Naltrexone: pregnancy, acute hepatitis, hepatic failure
  - Monitor LFTs.
- Precautions: organic pain, organic brain syndromes
- Significant possible interactions: alcohol, sedatives, hypnotics, naltrexone, and narcotics

**ALERT**
Treat acute symptoms if in alcohol withdrawal; give thiamine 100 mg/day with first dose prior to glucose.

Second Line
- Disulfiram: 250 to 500 mg/day PO; unproven efficacy; may provide psychological deterrent; most effective if used with close supervision (4)[A]
- Baclofen: Low dose (30 to 60 mg/day) has a more tolerable side effect profile and is possibly more efficacious than higher doses (>60 mg/day) (6)[A].
- Selective serotonin reuptake inhibitors may be beneficial if comorbid depression exists (3)[A].

ISSUES FOR REFERRAL
Addiction specialist, 12-step or long-term program, behavioral health professional

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Assess medical and psychiatric comorbidities.
  - CIWA >8: a 10-item scale used in the assessment and management of alcohol withdrawal
- Correct electrolyte imbalances, acidosis, and hypovolemia (treat if in alcohol withdrawal).
- Thiamine: 100 mg IM, followed by 100 mg PO; folic acid: 1 mg/day
- Benzodiazepines used to lower risk of alcohol withdrawal, seizures

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Outpatient detoxification: daily visits (not recommended for patients with heavy alcohol abuse)
- Early outpatient rehabilitation: weekly visits
- Detoxification alone is not sufficient.

PATIENT EDUCATION
- Center for Substance Abuse Treatment: (800) 662-HELP or https://www.samhsa.gov/find-help
- Alcoholics Anonymous: http://www.aa.org/
- Rational Recovery: https://rational.org/
- Secular Organizations for Sobriety: http://www.centerforinquiry.net/sos
- Alcohol Answers: http://www.alcoholanswers.org/: an evidence-based Web site for those seeking credible information on alcohol dependence and online support forums

PROGNOSIS
- Chronic relapsing disease; mortality rate more than twice general population, death 10 to 15 years earlier
- Abstinence benefits: survival, mental health, family, employment
- 12-step programs, cognitive behavior, and motivational therapies are often effective during 1st year following treatment.

COMPLICATIONS
- Psychosocial complications (family, employment, etc.)
- Cirrhosis (women sooner than men)
- GI malignancies
- Neuropathy, dementia, Wernicke-Korsakoff syndrome
- Stroke; ketoacidosis; infections
- Adult respiratory distress syndrome
- Depression; suicide; trauma

SEE ALSO

Alcohol Withdrawal; Substance Use Disorders

CODES

ICD10
- F10.10 Alcohol abuse, uncomplicated
- F10.20 Alcohol dependence, uncomplicated
- F10.239 Alcohol dependence with withdrawal, unspecified

CLINICAL PEARLS

- CAGE questionnaire: >2 “yes” answers is 74–89% sensitive, 79–95% specific for AUD; less sensitive for white women, college students, elderly; not an appropriate tool for less severe forms of alcohol abuse
- Single question for unhealthy use screening: “How many times in the last year have you had X
or more drinks in 1 day?” (X = 5 for men, 4 for women); 81.8% sensitive, 79% specific for AUDs

- National Institute on Alcohol Abuse and Alcoholism criteria for “at-risk” drinking: men >14 drinks a week or >4 per occasion; women: >7 drinks a week or >3 per occasion
ALCOHOL WITHDRAWAL
Ngozi Okorafor, MD • Crystal Nwagwu, MD

BASICS

DESCRIPTION
Alcohol withdrawal syndrome (AWS) is a spectrum of symptoms that results from abrupt cessation or reduction in alcohol intake, which has previously been heavy or prolonged. It ranges from minor symptoms such as anxiety, insomnia, and restlessness to major complications such as hallucinations, seizures, and delirium tremors. Symptoms generally start 6 to 24 hours after the last drink.

EPIDEMIOLOGY

Incidence
- 15.1 million Americans meet diagnostic criteria for alcohol use disorder (AUD).
  
Approximately 50% of those with AUD have experienced AWS in their lifetime.
- 8% of those admitted to the hospital are at risk for AWS.

Prevalence
- AUD is among the most prevalent mental disorder in the world with 12-month and lifetime prevalence of 13.9% and 29.1%, respectively
- Higher prevalence among men, whites, Native Americans, younger and unmarried adults, and those with lower socioeconomic status

ETIOLOGY AND PATHOPHYSIOLOGY

- Consumption of alcohol stimulates the effect of the inhibitory neurotransmitter γ-aminobutyric acid (GABA), which results in decreased excitability. With chronic alcohol ingestion, this repeated stimulation downregulates the inhibitory effects of GABA.
- Concurrently, alcohol ingestion inhibits the stimulatory effect of glutamate on the central nervous system (CNS), with chronic alcohol use upregulating excitatory N-methyl-α-aspartate glutamate receptors.
- When alcohol is abruptly stopped, the combined effect of a downregulated inhibitory neurotransmitter system (GABA modulated) and upregulated excitatory neurotransmitter system (glutamate modulated) results in brain hyperexcitability when no longer suppressed by alcohol; clinically seen as AWS

Genetics
Some evidence for a genetic basis of AUD

RISK FACTORS

- High tolerance, prolonged use, high quantities
- Previous alcohol withdrawal episodes, detoxifications, alcohol withdrawal seizures, and delirium tremens (DTs)
- Serious medical problems
- Concomitant benzodiazepine (BZD) use

Geriatric Considerations
Elderly with AUD are more susceptible to withdrawal, and chronic comorbid conditions place them at higher risk of complications from withdrawal; use of short-acting medications preferred for management

**Pregnancy Considerations**
Hospitalization or inpatient detoxification is usually required for treatment of acute alcohol withdrawal.

**GENERAL PREVENTION**
- The U.S. Preventive Services Task Force recommends routinely screening all patients for alcohol misuse (1)[B].
- Special attention should be paid to patient undergoing operative procedures, and elective surgeries should be postponed until 7 to 10 days after last drink.
- Screen with the CAGE to detect problematic alcohol use; positive screen is ≥2 “yes” responses
  - Feeling the need to Cut down
  - Annoyed by criticism about alcohol use
  - Guilt about drinking/behaviors while intoxicated
  - “Eye opener” to quell withdrawal symptoms
- Three-question AUDIT-C screening test is also useful to identify patients with problematic drinking or active alcohol use disorder: positive screen is ≥4 in men and ≥3 in women
  - How often did you have a drink containing alcohol in the past year?
  - How many drinks did you have on a typical day when you were drinking in the past year?
  - How often did you have six or more drinks on one occasion in the past year?

**COMMONLY ASSOCIATED CONDITIONS**
- General: poor nutrition, electrolyte abnormalities (hyponatremia, hypomagnesemia, hypophosphatemia), thiamine deficiency, dehydration
- GI: hepatitis, cirrhosis, esophageal varices, GI bleed
- Heme: splenomegaly, thrombocytopenia, macrocytic anemia
- Cardiovascular: cardiomyopathy, hypertension, atrial fibrillation, other arrhythmias, stroke
- CNS: trauma, seizure disorder, generalized atrophy, Wernicke-Korsakoff syndrome
- Peripheral nervous system: neuropathy, myopathy
- Pulmonary: aspiration pneumonitis or pneumonia; increased risk of anaerobic infections
- Psychiatric: depression, posttraumatic stress disorder, bipolar disease, polysubstance use disorder

**DIAGNOSIS**
- Diagnostic and Statistical Manual of Mental Disorders IV diagnostic criteria for AWS:
  - Two or more of the following present within a few hours to several days after the cessation or reduction of heavy and prolonged alcohol ingestion:
    - Autonomic hyperactivity (sweating, tachycardia)
    - Increased hand tremor
    - Insomnia
    - Psychomotor agitation
    - Anxiety
    - Nausea or vomiting
- Generalized tonic–clonic seizures
- Transient visual, auditory, or tactile hallucinations or illusions
  – When the above signs or symptoms cause disturbances in orientation, memory, attention, awareness, visuospatial ability, or perception.
  – When the above signs and symptoms are not secondary to an underlying medical condition or mental disorder.

**Clinical manifestations**
- AWS can be divided into stages based on time of onset and severity:
  - Minor withdrawal: onset 6 to 8 hours after cessation
    - Mild anxiety, restlessness, and agitation
    - Mild nausea/GI upset and decreased appetite
    - Sleep disturbance
    - Sweating
    - Mild tremulousness
    - Fluctuating tachycardia and hypertension
  - Major withdrawal: onset 24 to 72 hours after cessation
    - Marked restlessness and agitation
    - Moderate tremulousness with constant eye movements
    - Diaphoresis
    - Nightmares
    - Nausea, vomiting, diarrhea, anorexia
    - Marked tachycardia and hypertension
    - Alcoholic hallucinosis (auditory, tactile, or visual) may have mild confusion but can be reoriented.
  - DTs: onset 72 to 96 hours after cessation
    - Fever
    - Severe hypertension, tachycardia
    - Delirium
    - Drenching sweats
    - Marked tremors
    - Persistent hallucinations
  - Alcohol withdrawal–associated seizures are often brief, generalized tonic–clonic seizures, and typically occur 6 to 48 hours after last drink.

**HISTORY**
Essential historical information should be as follows:
- Duration and quantity of alcohol intake, time since last drink
- Previous episodes/symptoms of alcohol withdrawal, prior admissions for medically managed withdrawal
- Concurrent substance use
- Preexisting medical and psychiatric conditions, prior seizure activity
- Social history: living situation, social support, stressors, and triggers

**PHYSICAL EXAM**
Should include assessment of conditions likely to complicate or that are exacerbated by AWS
- Cardiovascular: arrhythmias, heart failure, coronary artery disease
- GI: GI bleed, liver disease, pancreatitis
Neuro: oculomotor dysfunction, gait ataxia, neuropathy  
Psych: orientation, memory (may be complicated by hepatic encephalopathy)  
General: hand tremor (six to eight cycles per second), infections

DIFFERENTIAL DIAGNOSIS
- Cocaine and amphetamines intoxication  
- Opioid, marijuana, and other sedating substances withdrawal  
- Anticholinergic drug toxicity  
- Neuroleptic malignant syndrome  
- ICU delirium  
- Liver failure  
- Sepsis, CNS infection, or hemorrhage  
- Mania, psychosis, anxiety or panic disorder  
- Thyroid crisis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Blood alcohol level, urine drug screen  
- Complete blood count; comprehensive metabolic panel  
- Lipase; amylase  
- Head CT for patients whose presentations differ from their typical withdrawal symptoms or mental status change is atypical for withdrawal  
- If first seizure, full neurologic workup, including EEG, brain imaging, and lumbar puncture

Follow-Up Tests & Special Considerations
- For patients reporting abnormal pain, elevate amylase or lipase, consider abdominal ultrasound or CT for further evaluation  
- Electrocardiogram is suggested for patients >50 years or for patients with history of cardiac problems

TREATMENT

GENERAL MEASURES
- Per America Society of Addiction Medication, goals of therapy:  
  - “to provide a safe withdrawal from the drug(s) of dependence and enable the patient to become drug-free”  
  - “to provide a withdrawal that is humane and thus protects the patient’s dignity”  
  - “to prepare the patient for ongoing treatment of his or her dependence on alcohol or other drugs.”  
- The Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar) is useful for determining medication dosing and frequency of evaluation for AWS. Severity of symptoms are rated on a scale from 0 to 7, with 0 being without symptoms and 7 being the maximum score (except orientation and clouding of sensorium, scale 0 to 4).  
  - Nausea and vomiting  
  - Tactile disturbances  
  - Tremor
- Auditory disturbances
- Paroxysmal sweats
- Visual disturbances
- Anxiety
- Headache or fullness in head
- Agitation
- Orientation and clouding of sensorium

The maximum CIWA-Ar score achievable is 67.
- Mild withdrawal = score <8: likely resolve without medication
- Moderate withdrawal = 8 to 14: often require management with medication
- Severe withdrawal = >15: are associated with the highest risk of seizures and development of DTs

Frequent reevaluation with CIWA-Ar score is crucial

MEDICATION

First Line
- BZD monotherapy remains the treatment of choice; it is associated with fewer complications compared with neuroleptics.
- BZD should be chosen based on the following considerations:
  - Agents with rapid onset control agitation more quickly (e.g., IV diazepam [Valium]).
  - Long-acting BZDs (diazepam, chlordiazepoxide [Librium]) are more effective at preventing breakthrough seizures and delirium management.
  - Short-acting BZDs (lorazepam [Ativan], oxazepam [Serax]) are preferable when prolonged sedation is a concern (e.g., elderly patients or other serious concomitant medical illness) and preferable when severe hepatic insufficiency may impair metabolism.
- BZD dosages will vary by patient.
- Can use symptom-triggered or fixed-schedule regimens
  - Symptom-triggered regimens have been found to require less BZD amounts and reduce hospitalization.
  - Fixed-schedule regimens more appropriate if nursing staff do not have training for symptom triggered, if patient with severe coronary artery disease, or if history of past withdrawal seizures
- Symptom-triggered regimen: Administer one of the following medications every hour when CIWA-Ar ≥8:
  - Chlordiazepoxide: 50 to 100 mg PO
  - Diazepam: 10 to 20 mg PO
  - Oxazepam: 30 to 60 mg PO
  - Lorazepam: 2 to 4 mg PO
- Fixed-schedule regimen: Administer one of the following medications every 6 hours:
  - Chlordiazepoxide: 50 mg PO for 4 doses and then 25 mg PO for 8 doses
  - Diazepam: 10 mg PO for 4 doses and then 5 mg PO for 8 doses
  - Lorazepam: 2 mg PO for 4 doses and then 1 mg PO for 8 doses
  - Important to monitor closely and provide additional BZDs if CIWA-Ar ≥8
- Thiamine: 50 to 100 mg daily IV or IM for at least 3 days
  - Do not administer IV glucose before giving thiamine because this may precipitate Wernicke encephalopathy and Korsakoff psychosis.
- Correct electrolyte abnormalities/imbalance as they occur
Second Line
- β-Blockers (e.g., atenolol or propranolol) and α₂-agonists (e.g., clonidine) help to control hypertension and tachycardia and can be used with BZDs. Not used as monotherapy, due to their inability to prevent DTs and seizures; may worsen underlying delirium
- Carbamazepine: not recommended as first-line therapy; associated with reduced incidence of seizures but more studies are needed
- If the patient exhibits significant agitation and alcoholic hallucinosis, an antipsychotic (haloperidol [Haldol]) can be used, but this requires close observation because it lowers the seizure threshold.
- Neuroleptic agents are not recommended as monotherapy

ADDITIONAL THERAPIES
Peripheral neuropathy and cerebellar dysfunction merit physical therapy evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Criteria for inpatient admission:
- CIWA-Ar score >15 or severe withdrawal
- Poor ability to follow up or no reliable social support
- Pregnancy
- History of severe withdrawal symptoms
- History of withdrawal seizures or DTs
- Concurrent psychiatric illness

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Managing alcohol withdrawal is only first step toward treating patient’s underlying AUD.
- Discharge arrangements should include:
  - Development of plan to engage patient in further treatment
  - Transition to outpatient substance use counseling, peer support groups, and/or residential treatment facility
  - Prescription of available medication-assisted treatment such as acamprosate (Campral), naltrexone (ReVia, Vivitrol), or disulfiram (Antabuse)
- Acamprosate (666 mg PO TID): glutamate and GABA modulator indicated to reduce cravings
  - Contraindications: renal impairment (CrCl <30 mL/min)
- Naltrexone (50 mg/day PO; 380 mg IM every 4 weeks): opiate receptor antagonist, theorized to attenuate pleasurable effects of alcohol and reduce craving. Initiate therapy after patient is opioid free for at least 7 days.
  - Contraindications: acute hepatitis/liver failure, concomitant opioid therapy
- Disulfiram (250 mg/day PO): irreversibly inhibits aldehyde dehydrogenase, blocking alcohol metabolism, leading to an accumulation of acetaldehyde
  - Second-line option due to limited evidence of efficacy for relapse prevention
  - Contraindications: concomitant use of metronidazole and ethanol-containing products, psychosis, severe myocardial disease, and coronary occlusion

Patient Monitoring
Frequent follow-up to monitor for relapse

**DIET**
Advance as tolerated

**PATIENT EDUCATION**
  (not spiritually based)
- FamilyDoctor.Org: alcoholism (Spanish resources available)

**PROGNOSIS**
Mortality from severe withdrawal (DTs) is 1–5%.

**COMPLICATIONS**
Occurs more frequently in individuals who have prior episodes of withdrawal or concomitant illnesses

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
Substance Use Disorders

**CODES**

**ICD10**
- F10.239 Alcohol dependence with withdrawal, unspecified
- F10.230 Alcohol dependence with withdrawal, uncomplicated
- F10.231 Alcohol dependence with withdrawal delirium

**CLINICAL PEARLS**
- Any BZD dose should be patient specific, sufficient to achieve and maintain a “light somnolence” (e.g., sleeping but easily arousable), and should be tapered off carefully even after AWS resolves to prevent BZD withdrawal.
- Administer thiamine before patient receives glucose so as not to precipitate Wernicke encephalopathy.
- Avoid administering diazepam and lorazepam intramuscularly because of erratic absorption.
- Managing AWS is the first step toward treating AUD. Ensure patient has outpatient follow-up to continue treatment.
ALOPECIA
Anastasia N. Gevas, DO • Kelli M. Gevas, MD

BASICS
DESCRIPTION
- Alopecia: absence of hair from areas where it normally grows
  - Anagen phase: growing hairs, 90% scalp hair follicles at any time, lasts 2 to 6 years
  - Catagen phase: regression of follicle, <1% follicles, lasts 3 weeks
  - Telogen phase: Resting phase lasts 2 to 3 months; 50 to 150 telogen hairs shed per day.
- Classified as scarring (cicatricial), nonscarring, or structural
- Scarring (cicatricial) alopecia
  - Inflammatory disorders leading to permanent hair loss and follicle destruction
  - Includes lymphocytic, neutrophilic, and mixed subtypes
- Nonscarring alopecia
  - Lack of inflammation, no destruction of follicle
  - Includes focal, patterned, and diffuse hair loss such as androgenic alopecia, alopecia areata (AA), telogen effluvium, anagen effluvium, syphilitic hair loss
- Structural hair disorders
  - Brittle or fragile hair from abnormal hair formation or external insult

EPIDEMIOLOGY
- Androgenic alopecia: onset in males between 20 and 25 years of age; onset in females prior to 40 years of age, affecting as many as 70% of women >65 years of age
- AA: onset usually prior to 30 years of age; men and women are equally affected; well-documented genetic predisposition

Incidence
Incidence greatest in Caucasians, followed by Asians, African Americans, and Native Americans; in females, 13% premenopausal, with as many as 70% females >65 years of age

Prevalence
- Androgenic alopecia: in males, 30% Caucasian by 30 years of age, 50% by 50 years of age, and 80% by 70 years of age
- AA: 1/1,000 with lifetime risk of 1–2%
- Scarring alopecia: rare, 3–7% of all hair disorder patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Scarring (cicatricial) alopecia
  - Slick smooth scalp without follicles evident
  - Inflammatory disorders leading to permanent destruction of the follicle; it is not known what causes inflammation to develop.
  - Three major subtypes based on type of inflammation: lymphocytic, neutrophilic, and mixed
  - Primary scarring includes discoid lupus, lichen planopilaris, dissecting cellulitis of scalp, primary fibrosing, among others.
  - Secondary scarring from infection, neoplasm, radiation, surgery, and other physical trauma,
including tinea capitis
– Central centrifugal cicatricial alopecia most common form of scarring hair loss in African American women; etiology unknown but likely secondary to hair care practices

**Non-scarring alopecia**
– Focal alopecia
– AA
  – Patchy hair loss, usually autoimmune in etiology, T cell–mediated inflammation resulting in premature transition to catagen then telogen phases
  – May occur with hair loss in other areas of the body (alopecia totalis [entire scalp]), alopecia universalis (rapid loss of all body hair)
  – Nail disease frequently seen
  – High psychiatric comorbidity (1)
– Alopecia syphilitica: “moth-eaten” appearance, secondary syphilis
– Postoperative, pressure-induced alopecia: from long periods of pressure on one area of scalp
– Temporal triangular alopecia: congenital patch of hair loss in temporal area, unilateral or bilateral
– Traction alopecia: patchy, due to physical stressor of braids, ponytails, hair weaves

**Pattern hair loss**
– Androgenic alopecia: hair transitions from terminal to vellus hairs
– Male pattern hair loss: androgen-mediated hair loss in specific distribution; bitemporal, vertex occurs where androgen sensitive hairs are located on scalp. This is a predominantly hereditary condition (2).
  – Increased androgen receptors, increased 5-α reductase leads to increased testosterone conversion in follicle to dihydrotestosterone (DHT). This leads to decreased follicle size and vellus hair (2).
  – Norwood Hamilton classification type I to VII
  – Female pattern hair loss: thinning on frontal and vertex areas (Ludwig classification, grade I to III). Females with low levels of aromatase have more testosterone available for conversion to DHT (3). This carries an unclear inheritance pattern (2).
  – Polycystic ovarian syndrome, adrenal hyperplasia, and pituitary hyperplasia all lead to androgen changes and can result in alopecia.
  – Drugs (testosterone, progesterone, danazol, adrenocorticosteroids, anabolic steroids)

**Trichotillomania**: intentional pulling of hair from scalp; may present in variety of patterns

**Diffuse alopecia**
– Telogen effluvium: sudden shift of many follicles from anagen to telogen phase resulting in decreased hair density but not bald areas
  – May follow major stressors, including childbirth, injury, illness; occurs 2 to 3 months after event
  – Can be chronic with ongoing illness, including SLE, renal failure, IBS, HIV, thyroid disease, pituitary dysfunction
  – Adding or changing medications (oral contraceptives, anticoagulants, anticonvulsants, SSRIs, retinoids, β-blockers, ACE inhibitors, colchicine, cholesterol-lowering medications, etc.)
  – Malnutrition from malabsorption, eating disorders; poor diet can contribute.
– Anagen effluvium
  – Interruption of the anagen phase without transition to telogen phase; days to weeks after
inciting event
  o Chemotherapy is most common trigger.
  o Radiation, poisoning, and medications can also trigger.

- Structural hair disorders
  - Multiple inherited hair disorders including Menkes disease, monilethrix, and so forth. These result in the formation of abnormal hairs that are weakened.
  - May also result from chemical or heat damaging from hair processing treatments

**Genetics**
- Family history of early patterned hair loss is common in androgenic alopecia, also in AA.
- Rare structural hair disorders may be inherited.

**RISK FACTORS**
- Genetic predisposition
- Chronic illness including autoimmune disease, infections, cancer
- Physiologic stress including pregnancy and childbirth
- Poor nutrition
- Medication, chemotherapy, radiation
- Hair chemical treatments, braids, weaves/extensions

**GENERAL PREVENTION**
Minimize risk factors where possible.

**COMMONLY ASSOCIATED CONDITIONS**
- See “Etiology and Pathophysiology.”
- Vitiligo—4.1% patients with AA; may be the result of similar autoimmune pathways (4)

**DIAGNOSIS**

**HISTORY**
- Description of hair loss problem: rate of loss, duration, location, degree of hair loss, other symptoms including pruritus, infection, hair care, and treatments
- Medications
- Medical illness including chronic disease, recent illness, surgeries, pregnancy, thyroid disorder, iron deficiency, poisonings, exposures
- Psychological stress
- Dietary history and weight changes
- Family history of hair loss or autoimmune disorders

**PHYSICAL EXAM**
- Pattern of hair loss
  - Generalized, patterned, focal
  - Assess hair density, vellus versus terminal hairs, broken hair.
- Scalp scaling, inflammation, papules, pustules
- Presence of follicular ostia to determine class of alopecia
- Hair pull test
  - Pinch 25 to 50 hairs between thumb and forefinger and exert slow, gentle traction while
sliding fingers up.
  - Normal: 1 to 2 dislodge
  - Abnormal: ≥6 hairs dislodged
  - Broken hairs (structural disorder)
  - Broken-off hair at the borders patch that are easily removable (in AA)
- Hair loss at other sites, nail disorders, skin changes
- Clinical signs of thyroid disease, lupus, or other diseases
- Clinical signs of virilization: acne, hirsutism, acanthosis nigricans, truncal obesity

**DIFFERENTIAL DIAGNOSIS**
Search for type of alopecia and then for reversible causes.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No testing may be indicated depending on clinical appearance.
- Nonandrogenic alopecia
  - TSH, CBC, ferritin
  - Consider: LFT, BMP, zinc, VDRL, ANA, prolactin all depending on clinical history and exam
- Androgenic alopecia: especially in females
  - Consider free testosterone and dehydroepiandrosterone sulfate.

**Diagnostic Procedures/Other**
- Light hair-pull test: Pull on 25 to 50 hairs; ≥6 hairs dislodged is consistent with shedding (effluvium, AA).
- Direct microscopic exam of the hair shaft
  - Anagen hairs: elongated, distorted bulb with root sheath attached
  - Telogen hairs: rounded bulb, no root sheath
  - Exclamation point hairs: club-shaped root with thinner proximal shaft (AA)
  - Broken and distorted hairs may be associated with multiple hair dystrophies.
- Biopsy: most important in scarring alopecia
- Ultraviolet light fluorescence and potassium hydroxide prep (to rule out tinea capitis)

**TREATMENT**

**GENERAL MEASURES**
- Consider potential harms and benefits to the patient prior to treatment. Many will gain an improved quality of life that is of benefit (2)[A].
- Stop any possible medication causes if possible; this will often resolve telogen effluvium (5)[C].
- Treat underlying medical causes (e.g., thyroid disorder, syphilis).
- Traction alopecia: Change hair care practices; education
- Trichotillomania: often requires psychological intervention to induce behavior change

**MEDICATION**
- Nonscarring
- Androgenic alopecia: Treatment must be continued indefinitely; can use in combination
- Minoxidil (Rogaine): 2% topical solution (1 mL BID) for women, 5% topical solution (1 mL BID) or foam (daily) for men; works in 60% of cases (3)[A]
  o Unclear mechanism of action; appears to prolong anagen phase
  o Adverse effects: skin irritation, hypertrichosis of face/hands, tachycardia; category C in pregnancy (3)[A]
- Finasteride (Propecia): 1 mg/day for men and women (off-label) (6)[A]; 30–50% improvement in males, poor data in females (2)[A]
  o 5α-reductase inhibitor, reduces DHT in system, increases total and anagen hairs, slows transition of terminal to vellus hairs
  o Works best on vertex, least in anterior, temporal areas
  o Adverse effects: loss of libido, gynecomastia, depression. Caution in liver disease; absolutely no use or contact during pregnancy, category X, reliable contraception required in female use (6)[A]
- Spironolactone (Aldactone): 100 to 200 mg/day (off-label) (3)[C]
  o Aldosterone antagonist, antiandrogen; blocks the effect of androgens, decreasing testosterone production
  o Adverse effects: dose dependent, hyperkalemia, menstrual irregularity, fatigue; category D in pregnancy
- Ketoconazole: decreases DHT levels at follicle, works best with minoxidil in female androgenic alopecia (6)[A]
- Combination: Finasteride + minoxidil has superior efficacy to monotherapy (2)[A].

AA: no FDA-approved treatment; high rate of spontaneous remission in patchy AA. Treatments all focus on symptom management rather than etiology.

Intralesional steroids
- Triamcinolone: 2.5 to 5.0 mg/mL (3)[C]
  o First line if <50% scalp involved
  o Inject 0.1 mL into deep dermal layer at 0.5 to 1.0 cm intervals with 1/2 in 30-gauge needle, every 4 to 6 weeks; maximum 20 mg per session (1)[C]
  o Adverse effects: local burning, pruritus, skin atrophy
  o Topical steroids: very limited evidence for efficacy
  o Betamethasone: 0.1% foam shows limited hair regrowth (1)[C].
  o Adverse effects: folliculitis, high relapse rate after discontinuation
  o Systemic glucocorticoids: Use in extensive, multifocal AA; may induce regrowth but requires long-term monthly treatment to maintain growth (1)[B]
  o Adverse effects: hyperglycemia, adrenal insufficiency, osteoporosis, cataracts, obesity
  o Psychiatric: SSRIs, psychiatric care, support groups
  - PUVA light therapy + prednisone: moderate effectiveness in diffuse AA
  - Tinea capitis: See “Tinea (Capitis, Corporis, Cruris)”

SURGERY/OTHER PROCEDURES

- Hair transplantation
- Wigs, hairpieces, extensions
- Surgical: graft transplantation, flap transplantation, or excision of the scarred area; used primarily in scarring alopecia
- Platelet-rich plasma: has been shown to restore dormant hair follicles and stimulate new hair growth
- Laser therapies to promote growth: lacks evidence
**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Many herbal medications are available; no clear evidence at this time
- Volumizing shampoos can help remaining hair look fuller.

**ONGOING CARE**

**DIET**
If nutritional deficit noted, supplementation may be necessary.

**PATIENT EDUCATION**
National Alopecia Areata Foundation: [www.naaf.org](http://www.naaf.org)

**PROGNOSIS**
- AA: often regrows within 1 year even without treatment. Recurrence common. 10% have severe, chronic form; poor prognosis more likely with long duration, extensive hair loss, autoimmune disease, nail involvement, and young age
- Telogen effluvium: maximum shedding 3 months after the inciting event and recovery following correction of the cause. Usually subsides in 3 to 6 months but takes 12 to 18 months for cosmetically significant regrowth; rarely, permanent hair loss, usually with long-term illness
- Anagen effluvium: Shedding begins days to a few weeks after the inciting event, with recovery following correction of the cause; rarely, permanent hair loss
- Traction alopecia: excellent prognosis with behavior modification
- Cicatricial alopecia: hair follicles permanently damaged; prognosis depends on type of alopecia and available treatments.
- Tinea capitis: excellent prognosis with treatment

SEE ALSO

- Hyperthyroidism; Lichen Planus; Lupus Erythematosus, Systemic (SLE); Polycystic Ovarian Syndrome (PCOS); Syphilis; Tinea (Capitis, Corporis, Cruris)
- Algorithm: Alopecia

CODES

ICD10

- L65.9 Nonscarring hair loss, unspecified
- L64.9 Androgenic alopecia, unspecified
- L63.9 Alopecia areata, unspecified

CLINICAL PEARLS

- History and physical are necessary in determining type of alopecia for appropriate treatment.
- Treatment of underlying medical condition or removal of triggering medication will often resolve hair loss.
- Educating the patient about the nature of the condition and expectations is key to care.
- Alopecia can affect the psychological condition of the patient, and it may be necessary to address this in any type of hair loss.
ALTITUDE ILLNESS
Stephen E. Meyers, MD  ●  Linda Meyers, MD

BASICS

DESCRIPTION

- A spectrum of cerebral and pulmonary syndromes ranging from mild discomfort to fatal illness that occurs on ascent to higher altitudes as a direct result of inadequate acclimatization.
- Categories of altitude: intermediate, 1,520 to 2,440 m; high, 2,440 to 4,270 m; very high, 4,270 to 5,490 m; and extreme, >5,490 m
- Altitude illness can affect anyone, including experienced and fit individuals. For most, it is an unpleasant (self-limited) syndrome that does not require medical intervention (1).
- Acute mountain sickness (AMS): Symptoms associated with a physiologic response to a hypobaric, hypoxic environment. Onset usually occurs within 6 to 12 hours after ascending >2,500 m. Neurologic symptoms predominate, ranging from mild/moderate headache and malaise to severe impairment.
- High-altitude pulmonary edema (HAPE): noncardiogenic pulmonary edema; typically after 2 or more days at altitudes >3,000 m, rare between 2,500 and 3,000 m.
- High-altitude cerebral edema (HACE): a potentially fatal neurologic syndrome considered to be the end stage of AMS; onset after at least 2 days at altitudes >4,000 m.
- System(s) affected: nervous/pulmonary (2)
- Synonym(s): mountain sickness

Geriatric Considerations

- Risk does not increase with age.
- Age alone should not preclude travel to high altitude; allow extra time to acclimate.
- Worsening of preexisting medical problems referred to as altitude-exacerbated conditions.

Pediatric Considerations

- Altitude illness seems to have the same incidence in children as in adults; diagnosis may be delayed in younger children.
- Any child who experiences behavioral symptoms after recent ascent should be presumed to have an altitude-related illness.

Pregnancy Considerations

- The risk during pregnancy is unknown.
- No evidence suggests that exposure to high altitudes (1,500 to 3,500 m) poses a risk to a pregnancy.

EPIDEMIOLOGY

Most epidemiologic studies are limited to relatively homogeneous male populations.

Incidence

- AMS: 10–25% of unacclimatized persons who ascend to 2,500 m; 50–85% at altitudes of 4,500 to 5,500 m.
- HAPE/HACE: 0.5–1.0% of unacclimatized persons with 2 or more days of exposure at
altitudes exceeding 3,000 m. Risk increases with rate of ascent.

- Above 2500 m (8200 ft), for every 1000-m increase in altitude, there is a 13% increase in the AMS (3).

ETIOLOGY AND PATHOPHYSIOLOGY

- Individuals with a prior history of AMS, HACE, or HAPE are at a higher risk of recurrent AMS.
- Hypobaric hypoxia and hypoxemia are the pathophysiologic precursors to altitude illness.
- Symptoms of AMS may be the result of cerebral swelling, either through vasodilatation induced by hypoxia or through cerebral edema.
- Other mechanisms include impaired cerebral autoregulation, release of vasogenic mediators, and alteration of the blood–brain barrier.
- HAPE is a noncardiogenic pulmonary edema characterized by exaggerated pulmonary hypertension leading to vascular leakage through overperfusion, stress failure, or both.

Genetics

Genetic factors involved in predisposition to developing AMS are poorly understood.

RISK FACTORS

- Failure to properly acclimatize at a lower altitude
- Ascent rate >300 to 500 m/day
- Extreme altitude
- Increased duration at high altitude
- Higher altitude during sleep cycle
- Prior history of altitude illness
- Cardiac congenital abnormalities
- Female gender
- History of migraines (4)
- Younger age (<46 years)
- History of anxiety (5)

GENERAL PREVENTION

- General guidelines
  - Preacclimatization protects against altitude illness.
  - >2,500 m, do not ascend faster than 500 m/day; rest every 3 to 4 days (2).
  - Lower sleeping elevation: “Climb high and sleep low” for anyone going >3,500 m.
  - Avoid heavy exertion for the first 1 to 3 days at altitude.
  - Avoid respiratory depressants (alcohol and sedatives).
  - Preascent physical conditioning is not preventive.
- Pharmacologic prophylaxis
  - Acetazolamide, dexamethasone, and ibuprofen (see “Treatment”)
  - For prevention of HAPE only (if at risk):
    - Consider nifedipine, β-agonists, and tadalafil (see “Treatment”).

DIAGNOSIS

HISTORY
AMS: mild to moderate symptoms
  – Headache, plus at least one of:
    o Anorexia
    o Nausea or vomiting
    o Dizziness or light-headedness
    o Insomnia
AMS: severe symptoms
  – Severe headache
  – Irritability
  – Marked fatigue
  – Dyspnea with exertion
  – Nausea and vomiting
HAPE: Lake Louise diagnostic criteria
  – At least two of the following: dyspnea at rest, cough, weakness, decreased exercise performance, chest tightness, congestion
  – AND at least two of the following: crackles or wheezing in at least one lung field, central cyanosis, tachycardia, tachypnea (Note: Fatigue may be a sign of pulmonary edema.)
HACE symptoms: altered mental status (irrational behavior, lethargy, obtundation, coma)
  – May progress to ataxia and confusion (2)

PHYSICAL EXAM
HAPE
  – Lung crackles or wheezing
  – Central cyanosis
  – Tachycardia
  – Tachypnea
HACE
  – Abnormal mental status exam (behavioral change, lethargy, obtundation, coma)
  – Truncal ataxia
  – Papilledema, retinal hemorrhage, cranial nerve palsies
  – Focal neurologic deficits (rare)

DIFFERENTIAL DIAGNOSIS
AMS/HACE
  – Dehydration
  – Ingestion of toxins, drugs, or alcohol
  – Subarachnoid hemorrhage, CNS mass, cerebrovascular accident
  – Migraine headache
  – Carbon monoxide exposure
  – CNS infection
  – Acute psychosis
HAPE
  – Pneumonia
  – Cardiogenic pulmonary edema
  – Spontaneous pneumothorax
  – Pulmonary embolism
  – Asthma
Bronchitis
Myocardial infarction
Hyperventilation syndrome

Onset of symptoms >3 days at a given altitude, the absence of headache, or the lack of rapid response to oxygen or descent suggests an alternative diagnosis.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- AMS: Laboratory studies are nonspecific and rarely required for diagnosis.
- HAPE: Severe hypoxemia demonstrated with oximetry or blood gas analysis.
- Chest radiographs usually show patchy infiltrates. Clear lung fields suggest an alternate diagnosis.
- ECG may show sinus tachycardia or right-sided heart strain (1).

**TREATMENT**

**GENERAL MEASURES**
- Individuals without previous altitude exposure should adhere to acclimatization guidelines.
- Stop ascent, acclimatize at the same altitude, and/or descend if symptoms do not abate over 24 hours. Definitive treatment is to descend to a lower altitude. Dramatic improvement accompanies even modest reductions in altitude.
- Oxygen helps relieve symptoms. Give continuously by cannula or mask, and titrate to SaO₂ >90% (1).
- Given that most high-altitude travel is recreational and acetazolamide has side effects, prophylaxis is not generally recommended in children (6).
- AMS
  - Acetazolamide reduces mild to moderate symptoms of AMS (see “Medication”).
  - Dexamethasone may also be effective in treating moderate AMS (see “Medication”).
- HAPE
  - Oxygen therapy
  - Minimize exertion and keep patient warm.
  - Immediate descent or evacuation to a lower altitude
  - Portable hyperbaric therapy (2 to 15 psi using Gamow bag or Chamberlite) is an effective and practical alternative when descent is not possible.
  - Nifedipine (see “Medication”)
- HACE
  - Immediate descent
  - Supplemental oxygen (highest flow available; maintain SaO₂ >90%)
  - Dexamethasone (see “Medication”)
  - Portable hyperbaric therapy if available and unable to descend

**MEDICATION**

**First Line**
- Oxygen: 2 to 15 L/min to maintain SaO₂ >90% until symptoms improve
- Acetazolamide: If patient has a history of problems at altitude and/or plans to ascend >500
m/day above 2,500 m, consider therapy for primary prevention. Avoid in patients with a sulfonamide allergy.

- Primary prevention of AMS: 62.5 to 250 mg PO BID starting 8 to 24 hours before ascent and continued for 2 days at a stable altitude; not recommended for children as a preventive medication (7,8)[A]
- Recent data indicates that lower acetazolamide dosing is noninferior to higher doses (7).
- Treatment of AMS: 250 mg PO BID until symptoms resolve; pediatric dose: 2.5 mg/kg q12h (6)

- Dexamethasone: may significantly reduce the incidence and severity of AMS. Adverse side effects are rare (8)[A].
  - Prevention of AMS: 2 mg PO q6h or 4 mg PO q12h, starting 1 day before ascent and discontinued cautiously after 2 days at maximum altitude. Do not use for pediatric prevention (6).
  - Treatment of AMS: 4 mg PO/IV/IM q6h; pediatric dose: 0.15 mg/kg dose q6h (6)
  - Treatment of HACE: 8 mg PO/IV/IM initially and then 4 mg q6h; pediatric dose: 0.15 mg/kg dose q6h (6)

- Nifedipine (reduces pulmonary arterial pressure) (1)
  - Prevention of HAPE: 30 mg extended-release PO BID starting 1 day prior to ascent and continued for 2 days at maximum altitude
  - Treatment of HAPE: 30 mg extended-release PO q12h (likely unnecessary if oxygen is available)

- Tadalafil: Consider for the prevention of HAPE (1).
  - Prevention HAPE: 10 mg PO BID 1 day prior to ascent in HAPE susceptible individual

- Adjunct therapy
  - Salmeterol
    - Prevention and possible treatment of HAPE: 125 μg inhaled BID starting 1 day before ascent and continued for 2 days at maximum altitude
    - Recommended as adjunct to nifedipine
  - NSAIDs: Possible benefit in AMS prevention and treatment of associated headache.
    - Aspirin: 325 mg PO q4h for total 3 doses
    - Ibuprofen: 400 to 600 mg PO q8h
  - Antiemetics
    - Prochlorperazine: 10 mg PO/IM q6–8h
    - Promethazine: 25 to 50 mg PO/IM/PR q6h

- Other trialed therapies
  - Gingko balboa: No benefit over placebo in reducing the risk of AMS (9).
  - Simulated altitude or remote ischemic preconditioning (RIPC), as well as supplementation of antioxidants, medroxyprogesterone, iron, or Rhodiola crenulata lack quality evidence supporting their use (9).
  - Furosemide: previously studied for treatment of AMS or HACE, 20 to 80 mg PO/IV q12h for a total of 2 doses. Currently out of favor; not recommended for prophylaxis; not established for use in HAPE.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient treatment for mild cases
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- For mild cases, no follow-up is needed.
- For more severe cases, follow closely until symptoms subside.

PATIENT EDUCATION

Counsel patients about the risks of high-altitude travel and how to recognize symptoms of high-altitude illness.

PROGNOSIS

Most cases of mild to moderate AMS are self-limiting and do not require medical intervention. Patients may resume ascent once the symptoms subside. HAPE and HACE respond well to descent, evacuation, and/or pharmacologic treatment if identified early.

COMPLICATIONS

High-altitude retinal hemorrhage can cause visual changes, but is usually asymptomatic.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- T70.20XA Unspecified effects of high altitude, initial encounter
- T70.20XD Unspecified effects of high altitude, subsequent encounter
- T70.20XS Unspecified effects of high altitude, sequela

**CLINICAL PEARLS**
- Slow ascent and timely descent are important to prevent and treat high-altitude illnesses.
- Lack of symptom resolution with appropriate descent suggests an alternative diagnosis.
- High-flow oxygen, followed by oxygen titrated to maintain \( \text{SaO}_2 > 90\% \), is the first-line treatment for all patients with more than mild altitude illness.
ALZHEIMER DISEASE
John P. Barrett, MD, MPH, MS, FAAFP, FACPM

BASICS

DESCRIPTION
- Alzheimer disease (AD) is the most common cause of dementia: 60–80% are afflicted with dementia.
- AD is a progressive, irreversible, degenerative neurologic disease that results in neuron death.
- AD is the sixth leading cause of death in the United States (1).
- People ≥65 years with new AD live 4 to 8 years on average.
- AD is underdiagnosed (~50%), and many people diagnosed with AD are unaware of diagnosis (>50%).
- Economic burden in 2018: >$277 billion, projected at $1.1 trillion by 2050
- Dementia should be distinguished from:
  - Age-related cognitive decline: lifelong process of changes in mental ability and memory; highly variable and part of normal aging
  - Mild cognitive impairment (MCI): greater impairment than cognitive decline with individual and/or friends—family able to note impairment
    - MCI: People are generally able to live independently from a cognitive perspective.
    - MCI: affects 15–20% of those ≥65 years, with 32–38% developing dementia within 5 years
- AD diagnostic classification:
  - Preclinical AD: research settings only at this time; no cognitive symptoms, AD biomarkers present
  - MCI due to AD: if AD biomarkers present and not attributed to other causes; impairment often only in memory; no major social/occupational deficits
  - Dementia due to AD:
    - Early stage: memory impairment beyond MCI
    - Middle stage: impairment in communication and response to environment
    - Late stage: lose ability to appropriately recognize and respond to environment
- System affected: nervous
- Synonym(s): presenile dementia; senile dementia of the Alzheimer type

Geriatric Considerations
- “Welcome to Medicare” preventive visit (first 12 months of enrollment) and Medicare Annual Wellness Visit both require assessment of cognitive function.
- The U.S. Preventive Services Task Force has a grade I (insufficient evidence) recommendation on asymptomatic routine screening for dementia, although cognitive assessment is required for Medicare Initial and Annual Wellness Visits.
- Advanced care planning is Medicare reimbursable

EPIDEMIOLOGY
- Predominant age: >65 years
- Incidence: females = males
Prevalence: females > males, due to longer average lifespan in women

Incidence
New cases of AD in the United States: 484,000/year
- 65 to 75 years: 2 new cases per 1,000 people
- 75 to 84: 11 new cases per 1,000 people
- ≥85: 37 new cases per 1,000 people

Prevalence
>5.7 million in United States; ~44 million worldwide
- 14.4 million in United States by 2050
- 1 in 10 of those ≥65 years have AD dementia.
- 32% of those ≥85 years have AD dementia.
- ~200,000 in United States with early-onset AD (<65 years)

ETIOLOGY AND PATHOPHYSIOLOGY
- Progressive, irreversible disease where cognitive impairment worsens over time
- Caused by β-amyloid plaques outside of neurons and τ protein tangles inside of neurons, resulting in loss of connections between neurons and cell death
- Age, genetics, systemic disease, lifestyle behaviors, and other factors may influence AD progression.

Genetics
- Autosomal dominant: <5% of AD, usually early onset (<65 years)
- Familial inheritance AD (nonautosomal dominant): 15–25% of AD, may be early- or late-age onset
- Sporadic, idiopathic: most of AD

RISK FACTORS
- Nonmodifiable risk factors:
  - Age
  - Gender (due to longer lifespan in women)
  - Family history
  - Genetic mutations
  - APOE-e4 gene variant: e4 heterozygous 2- to 3-fold risk; homozygous 8-fold risk (vs. e2 or e3)
- Cardiovascular disease–related risk factors:
  - Hypertension (HTN) (especially in midlife years)
  - Obesity
  - Diabetes and impaired glucose processing
  - Hyperlipidemia
  - Tobacco use
  - Unhealthy diet
  - Lack of physical activity/exercise
  - Cerebrovascular (stroke) risks and injury
- Other potentially modifiable risk factors:
  - Less years of formal education (<8th grade)
  - Lack of continuous brain activity—learning
- Traumatic brain injuries: repetitive mild and moderate/severe
- Lack of social engagement
- Late-life depression
- Poor quality and inadequate sleep
- Hearing and vision deficits
- High alcohol consumption
- Possible environmental factors (e.g., pollution)

**GENERAL PREVENTION**

- Slowing/preventing cognitive decline, MCI, and AD are the top interest and concern of Americans ≥50 years.
- Evidence suggests that HTN management, increased physical activity, cognitive training may delay/prevent cognitive decline, MCI, and AD.
- NSAIDs, estrogen, and vitamin E do not delay AD onset; insufficient evidence for statins and proton pump inhibitors
- Healthy lifestyle (e.g., exercise, sleep), potentially modifiable risk factors, may prevent or delay AD at the individual and population health level.
- Actions to avert delirium during hospitalizations
- Treat psychiatric conditions (e.g., depression).
- Numerous medication can cause decreased cognition and delirium in the elderly.

**COMMONLY ASSOCIATED CONDITIONS**

- Down syndrome
- Depression

**DIAGNOSIS**

Diagnosis of dementia is straightforward. Diagnosis of the specific dementia–type cause may not be straightforward and requires a thorough history, examination, cognitive testing, and potentially other diagnostic tests.

- 2000 DSM-IV-TR criteria widely in use: progressive impairment in ≥2 areas of memory, executive function, attention, language, or visuospatial skills and significant interference in ability to function in work, home, or social interactions
- 2013 DSM-5 uses term “neurocognitive disorder” instead of dementia and requires impairment in one or more cognitive areas sufficient to disrupt independent living:
  - Complex attention, executive function, learning and memory, language, perceptual motor, social cognition

**HISTORY**

- Include informant: family member, caregiver, or friend.
- Alzheimer’s Association 10 signs:
  - Memory loss that disrupts daily life
  - Difficulty completing familiar tasks
  - Challenges in planning and problem-solving
  - New problems with words in speaking or writing
  - Trouble with visual images or spatial relationships
  - Changes in mood or personality
– Misplacing things, losing ability to retrace steps
– Decreased or poor judgment
– Withdrawal from work or social activities
– Confusion with time and place

PHYSICAL EXAM
● Exam to rule out other causes of dementia or delirium
● Noncognitive portions of physical exam often normal for age except in late stage AD
● Vital signs, cardiovascular exam
● Speech and language, vision and hearing
● Neuro: gait, balance, reflexes, muscle strength and tone, tremor, abnormal movements (akathisia, bradykinesia/dyskinesia)
● Late stage: skin lesions, nutrition–hydration status
● Brief cognitive testing: for example, Mini-Cog, Montreal Cognitive Assessment (MoCA), Mini-Mental State Examination (MMSE, under copyright, fee for use)
● Assess depression: for example, Patient Health Questionnaire-9, Geriatric Depression Scale (GDS).
● Functional assessment: instrumental activities of daily living (IADLs), Functional Activities Questionnaire (FAQ)

DIFFERENTIAL DIAGNOSIS
● Other dementias (most common):
  – Vascular (large and microvessel, mixed)
  – Mixed type (with AD)
  – Frontotemporal lobar degeneration
  – Dementia with Lewy bodies
  – Parkinson
  – Normal pressure hydrocephalus
  – Creutzfeldt-Jakob
  – Huntington
  – Wernicke-Korsakoff
● Metabolic: hyper/hypothyroid, vitamin-nutrient deficiency, uremia/renal, hepatic, hyponatremia
● Autoimmune: vasculitis, end-stage multiple sclerosis
● Infectious: HIV, syphilis, Lyme disease, varicella-zoster virus, prion
● Depression
● Brain tumor: primary or metastatic
● Subdural hematoma (usually acute presentation)
● Medications, drug–alcohol reactions/addiction

DIAGNOSTIC TESTS & INTERPRETATION
Specialty referral and possible neuropsychological testing for atypical symptoms, young age, unclear presentation, or if resources available and need to determine level of independent decision making

Initial Tests (lab, imaging)
● To help rule out other causes of dementia (1)[A]
  – Complete blood count with differential; homocysteine level
- Chemistry panel: electrolytes, blood urea nitrogen, serum creatinine, glucose, liver function tests, serum calcium-magnesium
- Thyroid function, lipid panel, and vitamin B\textsubscript{12}
- Special considerations: erythrocyte sedimentation rate, venereal disease research laboratory or rapid plasma reagin, HIV, folate, C-reactive protein, HgbA1c
- Imaging (biomarkers): Different standards exist; may help determine cause of dementia (1)[A]
  - Consider MRI (preferred) or computed tomography scan (CT if MRI contraindicated)
    o Initial AD evaluation, and if cognitive decline is recent and rapid, age <65 years, history of stroke, atypical presentation
    o Concern for cancer, bleeding risk
  - Single photon emission CT (SPECT) and positron emission tomography (PET): rarely indicated; insufficient evidence to use alone

Follow-Up Tests & Special Considerations
- Consider genetic testing for concern about autosomal dominant and familial AD.
- Cerebrospinal fluid biomarker testing not currently indicated in routine clinical use, although extensive study in research settings

Test Interpretation
Labs, neuropsychiatric testing, and imaging help exclude treatable and atypical causes of dementia.

![TREATMENT]

GENERAL MEASURES
- Optimize treatment of risk factors and associated comorbid conditions (e.g., hearing and vision loss).
- Assess environment for safety/security; avoid sudden changes to environment.
- Advanced care planning is critical early, before individual loses ability for independent decisions.
- Assess caregiver support and burnout.

ALERT
American Geriatrics Society recommends “Don’t prescribe cholinesterase inhibitors (ChEIs) for dementia without periodic assessment for perceived cognitive benefits and adverse gastrointestinal effects” in their Choosing Wisely statement.

MEDICATION
First Line
- Acetylcholinesterase Inhibitors (ChEIs) (1)[A]
  - Best in mild to moderate disease; may be effective in Lewy body dementia
  - Equally effective; all have potential for GI and other side effects, such as bradycardia/syncope.
  - When used for at least 6 months, it provide mild benefit in cognition and behavior.
  - Try different ChEI if no benefit.
  - Donepezil (Aricept): Start at 5 mg/day PO; may increase to 10 mg/day after 1 month, may
increase to 23 mg/day after 3 months if needed
- Orally disintegrating tablets; generic available
- Caution with digoxin or β-blockers (Donepezil may prolong PR interval.)
- Rivastigmine (Exelon): Start at 1.5 mg PO BID and increase by 1.5 mg BID every 2 weeks; maintenance 6 to 12 mg/day total
- Capsule, solution, or patch (reduced side effects)
- Galantamine (Razadyne): Start at 4 mg BID for 4 weeks and then increase by 4 mg BID every month with goal of 16 to 24 mg/day dose.
- Tablets, solution, extended-release (ER) capsule, and transdermal formulations

- Vitamin E—2,000 IU/day supplementation was found to slow decline in one study.
- Memantine, a N-methyl-d-aspartate (NMDA) receptor antagonist for moderate to severe AD
  - Monotherapy or in combination with acetylcholinesterase inhibitors
  - Memantine immediate release: 5 mg/day; titrate up to 10 mg BID, adding 5 mg/day every week PRN.
  - Memantine extended release: 7 mg/day up to 28 mg/day, adding 7 mg/day every week PRN
- Neuropsychiatric symptoms: assessment and treatment for delirium, environmental modification, sleep hygiene, exercise, cognitive interventions, hearing/vision aids, and if necessary for moderate to severe symptoms, consider second-line care

**Second Line**
- For moderate to severe depression: selective serotonin reuptake inhibitors (SSRIs) preferred
- Insomnia: Medications have little efficacy for sleep in AD.
  - Avoid diphenhydramine and antihistamines in elderly due to negative side effects.
  - If using low-dose risperidone, trazodone, or sleep aid (e.g., zolpidem), use caution and lowest dose possible in elderly.
- Moderate agitation, anxiety/restlessness: first-line care; may consider low-dose risperidone or SSRIs (citalopram)
- Risperidone at low dose for severe psychosis and safety concern; treatment not usually required
- Precautions
  - Avoid anticholinergic drugs when possible.
  - Benzodiazepines may produce paradoxical excitation or daytime drowsiness.
  - Triazolam (Halcion) can produce confusion, memory loss, and psychotic behavior.
  - Donepezil: caution with anticholinergics, sick sinus syndrome, and history of peptic ulcers

**ISSUES FOR REFERRAL**
- Consider geriatric psychiatry referral for AD patients with behavioral symptoms requiring psychotropic medications.
- Support groups for patient and family: Alzheimer’s Association: https://www.alz.org/

**ADDITIONAL THERAPIES**
- Exercise to reduce restlessness.
- Cognitive stimulation therapy
- Occupational, music, aroma, and pet therapy

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- In general, herbals and supplement therapies have questionable to no efficacy in AD.
- Exercise, cognitive interventions, and environmental therapies have benefit in AD and
ongoing care

follow-up recommendations

patient monitoring

- Review all health conditions and medications, including over-the-counters, vitamins, and supplements.
- Recommend:
  - Healthy lifestyle: exercise, nutrition, sleep, being socially and intellectually active
  - Cognitive training/stimulation
- Inform about products advertised (with unproven benefit) to improve brain health, such as some medications, nutritional supplements, and brain games.
- Until dose stable, frequently assess medication side effects and effectiveness (ChEIs/memantine).
- Late AD may require skilled care placement.

patient education

- Alzheimer’s Association: https://www.alz.org/
- Explain progressive nature of the disease.
- Early advanced care planning, such as advanced directives, financial planning, caregiver support

prognosis

Average survival from diagnosis is 4 to 8 years, and initial diagnosis is often delayed.

complications

- Behavioral: hostility, agitation, wandering, falls
- Infections, inadequate nutrition/hydration, drug toxicity
- “Sundowning,” depression (1/3 of patients), suicide

references

Delirium; Depression; Hypothyroidism, Adult; Substance Use Disorders
CODES

ICD10
- G30 Alzheimer’s disease
- G30.1 Alzheimer’s disease with late onset
- G30.9 Alzheimer’s disease, unspecified

CLINICAL PEARLS
- AD is very common, >32% in those >85 years, and greatly underdiagnosed.
- Imaging not needed for diagnosis for typical AD
- Early diagnosis allows advance care planning (e.g., advanced directives) and caregiver support planning: Encourage caregivers to join Alzheimer’s Association.
- Atypical antipsychotic medications increase mortality.
AMENORRHEA
Thomas A. Waller, MD ● Sally-Ann L. Pantin, MD, FAAFP

BASICS

DESCRIPTION

- Primary amenorrhea
  - No menses by age 13 years with absence of secondary sexual characteristics OR
  - No menses by age 15 years with normal secondary characteristics
- Secondary amenorrhea: cessation of menses for 3 months if previously normal menstruation or 6 months if a history of irregular cycles
- System(s) affected: endocrine/metabolic; reproductive

Pregnancy Considerations
Pregnancy is by far the most common cause of secondary amenorrhea.

EPIDEMIOLOGY

Prevalence

- Primary amenorrhea: <1% of female population
- Secondary amenorrhea: 3–5% of female population
- No evidence for race and ethnicity affecting prevalence

ETIOLOGY AND PATHOPHYSIOLOGY

Absence of menses that can be temporary or permanent due to dysfunction of the hypothalamus, pituitary, uterus, ovaries, or vagina

ETIOLOGY

- Primary amenorrhea
  - Gonadal dysgenesis (e.g., Turner syndrome [45,X]) or failure (e.g., autoimmune, idiopathic)
  - Anatomic abnormalities (e.g., müllerian agenesis, imperforate hymen, transverse vaginal septum)
  - Hypothalamic–pituitary abnormalities
    - Functional hypothalamic amenorrhea (reduced GnRH secretion, e.g., weight loss/anorexia nervosa)
    - Constitutional delay of puberty
    - Central lesions (tumors, hypophysitis, granulomas)
    - Pituitary dysfunction (hyperprolactinemia, abnormal follicle-stimulating hormone [FSH], luteinizing hormone [LH], or GnRH)
    - Thyroid dysfunction
  - Polycystic ovarian syndrome (PCOS)
  - Androgen insensitivity syndrome
- Secondary amenorrhea
  - Pregnancy
  - Hypothalamic dysfunction (reduced GnRH secretion)
    - Functional hypothalamic amenorrhea (stress, anorexia nervosa, and/or excessive exercise)
    - Hypothalamic tumors
Severe systemic illness (e.g., diabetes mellitus type 1 or celiac disease)
– Pituitary disease (e.g., hyperprolactinemia, Sheehan syndrome, Cushing syndrome)
– Thyroid disease
– PCOS
– Ovarian disorders (e.g., premature ovarian failure [due to chemotherapy, radiation, fragile X syndrome] or ovarian tumors)
– Uterine disorders (e.g., intrauterine adhesions [Asherman syndrome])

Pathophysiology varies, depending on etiology.

Genetics
May occur with Turner syndrome or testicular feminization

RISK FACTORS
• Obesity
• Excessive exercise (commonly associated “female athlete triad”)
• Eating disorders
• Malnutrition
• Anovulatory disorders
• Stress
• Treatment with antipsychotic medications

GENERAL PREVENTION
Maintenance of proper body mass index (BMI) and healthy lifestyle with respect to food and exercise

COMMONLY ASSOCIATED CONDITIONS
• Premature ovarian failure may be associated with autoimmune abnormalities (autoimmune thyroiditis, type 1 diabetes).
• PCOS is associated with insulin resistance and obesity.
• Decreased exposure to estrogen may increase risk for osteopenia or osteoporosis.

DIAGNOSIS
HISTORY
• Review of systems, including weight change, symptoms of pregnancy or menopause, virilizing changes, cyclic pelvic pain, galactorrhea, headaches, vision changes, fatigue, palpitations, polyuria/polydipsia
• Growth and pubertal development history, including age of breast development, pubertal growth spurt, and adrenarche (early sexual maturation)
• History of chronic illness, trauma, surgery, medications, prior chemotherapy or radiation
• Psychiatric history
• Social history, including diet and exercise history, drug abuse, and sexual history
• Family history of delayed or absent puberty

PHYSICAL EXAM
• General appearance
• Vital signs, height, weight, growth percentile and BMI, hypotension, bradycardia, hypothermia
HEENT exam: evidence of dental erosions, trauma to palate (bulimia), visual field defect, funduscopic changes, cranial nerve findings (prolactinoma), webbed neck (Turner syndrome), thyromegaly
- Skin exam: evidence of androgen excess (acne, hirsutism), acanthosis nigricans (PCOS), fine downy hair on body (anorexia nervosa), striae
- Breast: state of development, evidence of galactorrhea (prolactinoma), shield chest (Turner syndrome)
- Pelvic exam: presence or absence of pubic hair (if sparse: androgen insensitivity or deficiency); clitoromegaly (androgen excess); distention or bulging of external vagina (imperforate hymen); thin, pale vaginal mucosa without rugae (estrogen deficiency and ovarian failure); presence of cervical mucus (evidence for estrogen production); blind vaginal pouch (müllerian agenesis, androgen insensitivity syndrome); ovarian enlargement (tumors, PCOS, autoimmune oophoritis)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Primary amenorrhea
  - Serum human chorionic gonadotropin (hCG), prolactin (PRL), thyroid-stimulating hormone (TSH), and FSH
  - If no breast development:
    - FSH low suggests primary hypothalamic or pituitary etiology.
    - FSH elevated suggests gonadal failure, and karyotype analysis should be performed.
  - If breast development has occurred, evaluate for anatomic abnormalities. If uterus is absent or abnormal, perform karyotype analysis, testosterone level, and dehydroepiandrosterone sulfate (DHEA-S).
- Secondary amenorrhea
  - Serum hCG, PRL, TSH, and FSH
    - If PRL >100 ng/mL suggests empty sella syndrome or pituitary adenoma; perform MRI for evaluation.
    - If PRL <100 ng/mL: Evaluate for other etiologies, of which medications are most common.
  - To determine endogenous estrogen production, perform a progestin challenge (see “Treatment”): If withdrawal bleed, likely chronic anovulation (most commonly PCOS). If no withdrawal bleed, perform estrogen and progestin challenge (see “Treatment”):
    - If no bleed: Consider outflow tract obstruction.
    - If bleed occurs: Check FSH/LH: elevated in premature ovarian failure; decreased in pituitary tumors, eating disorders, chronic illness
- If there is evidence for hyperandrogenism, measure total testosterone, DHEA-S, and 17-OH progesterone levels. Initiate evaluation for androgen-secreting tumor if testosterone >200 ng/dL.
- Imaging is not generally indicated as a first approach.
- US may show ovarian cysts (PCOS), presence or absence of uterus, and endometrial thickness (consider MRI if unable to tolerate US probe).

**Follow-Up Tests & Special Considerations**
- Women <30 years with ovarian failure (see below) should have karyotype analysis and be
investigated for premutations of FMR1 gene (fragile X syndrome) and for adrenal antibodies.
- If absence of uterus or foreshortened vagina, karyotype analysis should also be performed.
- Laparoscopy: diagnosis of streak ovaries (Turner syndrome) or polycystic ovaries
- Hysterosalpingogram: Rule out Asherman syndrome and other etiologies of outflow obstruction.

Diagnostic Procedures/Other
- If constitutional delay is suspected, obtain bone age.
- If hypothalamic amenorrhea from functional suppression is suspected, consider dual energy x-ray absorptiometry (DEXA) scan to assess bone loss (1).

TREATMENT

GENERAL MEASURES
Identify and correct underlying pathology if possible.

MEDICATION
- Progesterone challenge and replacement: medroxyprogesterone (Provera): 10 mg/day for 10 days will result in withdrawal bleed within 7 days of last dose if hypothalamic–pituitary–gonadal axis is intact (i.e., amenorrhea is a consequence of anovulation and lack of progesterone), although experts disagree (2).
- Estrogen replacement: Cycling with a combination oral contraceptive (containing 35 or 50 μg of estrogen) or conjugated estrogen (Premarin) 0.625 mg for 25 days with progesterone added as above for the last 10 days will result in a withdrawal bleed if the uterus and lower genital tract are normal (hypothalamic-pituitary axis pathologic).
- Use of hormonal therapies will not correct the underlying problem. Other drugs might be required to treat specific conditions (e.g., bromocriptine for hyperprolactinemia).
- Use of hormonal replacement therapy is not recommended for long-term management of amenorrhea in older women.
  - May be safe for symptom management in young women
  - Give to maintain secondary sex characteristics and to prevent osteoporosis in adolescents and young women (3)[A].
- Combination estrogen/progesterone contraceptives (oral contraceptive pills [OCPs], patch, ring) replace estrogen and prevent pregnancy.
  - Have a positive effect on bone mineral density in oligo-/amenorrheic women but not in functional hypothalamic amenorrhea (4)[A]
  - Can decrease hirsutism in PCOS
- Calcium supplementation: 1,500 mg/day if cause is hypoestrogenism
- Because PCOS is related to insulin resistance, metformin (Glucophage) has been used (start at 500 mg BID) to correct metabolic abnormalities, improve ovulation, and restore normal menstrual patterns. Of note, treatment with metformin has shown an increase in clinical pregnancy rates but not in live birth rates (5)[A].
- Functional hypothalamic amenorrhea appears to improve with administration of exogenous leptin (still under investigation) (6)[C].
- Contraindications to estrogen administration
  - Pregnancy, thromboembolic disease, previous myocardial infarction or cerebrovascular
accident, estrogen-dependent malignancy, severe hepatic impairment or disease

Precautions
– Patients with amenorrhea who desire pregnancy should not be given hormone replacement therapy but should receive treatment for infertility based on the specific cause.

ISSUES FOR REFERRAL
Many causes of amenorrhea require referral to specialists in ob/gyn, endocrine, surgery, and/or psychiatry.

SURGERY/OTHER PROCEDURES
– Hymenectomy for primary amenorrhea if due to imperforate hymen
– Lysis of adhesions in Asherman syndrome is often effective in restoring regular menses and fertility.
– If karyotype is XY, gonads must be removed due to increased risk of tumors.
– Patients with congenital short vagina can undergo surgery to create a functioning vagina.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
If excessive exercise is suspected, activity level should be reduced by 25–50%.

Patient Monitoring
– Depends on the cause and treatment chosen
– If hormonal replacement is used, discontinue after 6 months to assess spontaneous resumption of menses.

DIET
– Correct overweight or underweight by dietary management and behavior modification.
– If PCOS is the etiology, a weight-loss diet will help restore ovulation.

PATIENT EDUCATION
– Educate on the circumstances and complications of her condition and its underlying etiology.
– Specific educational resources are helpful (e.g., prenatal classes and menopause support groups).
– Discuss the expected duration of amenorrhea (temporary or permanent), effect on fertility, and the long-term sequelae of untreated amenorrhea (e.g., osteoporosis, vaginal dryness).
– Appropriate contraceptive advice should be given because fertility returns before menses.
– Additional support may be needed if the amenorrhea is associated with a reduction in, or loss of, fertility.

PROGNOSIS
Reflects the underlying cause. In functional hypothalamic amenorrhea, one study demonstrated 83% reversal rate in presence of obvious contributing factor.

COMPLICATIONS
– Estrogen-deficiency symptoms (e.g., hot flashes, vaginal dryness) and osteoporosis in prolonged hypoestrogenic amenorrhea
– Increased risk of endometrial cancer in patients whose amenorrhea is secondary to anovulation
with estrogen excess (obesity, PCOS)

- Premature ovarian failure may increase cardiovascular risk.

ADDITIONAL READING

SEE ALSO

- Hyperthyroidism; Hypothyroidism, Adult; Osteoporosis and Osteopenia
- Algorithms: Amenorrhea, Primary (Absence of Menarche by Age 16 Years); Amenorrhea, Secondary; Delayed Puberty

CODES

ICD10

- N91.2 Amenorrhea, unspecified
- N91.0 Primary amenorrhea
- N91.1 Secondary amenorrhea

CLINICAL PEARLS

- First evaluate whether amenorrhea is primary or secondary and exclude pregnancy. TSH and PRL are usual first blood tests.
- Progestin challenge may cause withdrawal bleed in women with intact hypothalamic–
pituitary–gonadal axis.
ANAL FISSURE
Anne Walsh, ANP-BC • Jennifer Grumet, MD

BASICS
DESCRIPTION
Anal fissure (fissure in ano): longitudinal tear in the lining of the anal canal distal to the dentate line, most commonly at the posterior midline; characterized by a knifelike tearing sensation on defecation, often associated with bright red blood per rectum. This common benign anorectal condition is often confused with hemorrhoids; may be acute or chronic (>8 weeks) in duration or with the presence of hypertrophic papilla and sentinel pile (skin tag).

EPIDEMIOLOGY
- Affects all ages. Common in infants aged 6 to 24 months; not common in older children, suspect abuse, or trauma; elderly less common due to lower resting pressure in the anal canal
- Sex: male = female; women more likely to get anterior midline fissures (25%) versus men (8%)

Incidence
Exact incidence is unknown (1). Patients often treat with home remedies and do not seek medical care.

Prevalence
- 80% of infants, usually self-limited
- 10–20% of adults, most of whom do not seek medical advice

ALERT
- Lateral fissure: Rule out infectious disease.
- Atypical fissure: Rule out Crohn disease.

ETIOLOGY AND PATHOPHYSIOLOGY
High-resting pressure within the anal canal (usually as a result of constipation/straining) coupled with decreased perfusion of the posterior canal leads to ischemia of the anoderm, resulting in splitting of the anal mucosa during defecation and spasm of the exposed internal sphincter.

Genetics
None known

RISK FACTORS
- Constipation (25% of patients)
- Diarrhea (6% of patients)
- Passage of hard or large-caliber stool
- High-resting pressure of internal anal sphincter (prolonged sitting, obesity)
- Trauma (sexual activity or abuse, foreign body, childbirth, mountain biking)
- Prior anal surgery with scarring/stenosis
- Inflammatory bowel disease (Crohn disease)
- Infection (chlamydia, syphilis, herpes, tuberculosis)
GENERAL PREVENTION
All measures to prevent constipation; avoid straining and prolonged sitting on toilet.

COMMONLY ASSOCIATED CONDITIONS
Posterior midline location: Constipation, irritable bowel syndrome; other locations: Crohn disease, tuberculosis, leukemia, and HIV

DIAGNOSIS

HISTORY
- Severe, sharp rectal pain, often with and following defecation but can be continuous; some patients will see bright red blood on the stool or when wiping.
- Occasionally, anal pruritus or perianal irritation

PHYSICAL EXAM
- Gentle spreading of the buttocks with close inspection of the anal verge will reveal a tender, smooth-edged tear in the anodermal tissue, typically posterior midline, occasionally anterior midline, rarely eccentric to midline. Digital rectal exam and anoscopy are painful and can be deferred if inspection confirms the diagnosis.
- Minimal edema, erythema, or bleeding may be seen.
- Chronic fissures may demonstrate rolled edges, exposed muscle fibers, hypertrophic papillae at proximal end, and a sentinel pile (tag) at distal end.

DIFFERENTIAL DIAGNOSIS
- Thrombosed external hemorrhoid: swollen, painful mass at anal verge
- Perirectal abscess: tender, warm erythematous induration or fluctuance
- Perianal fistula: abnormal communication between rectum and perianal epithelium with feculent or purulent drainage
- Pruritus ani: shallow excoriations and erythema rather than true fissure

DIAGNOSTIC TESTS & INTERPRETATION
Diagnostic Procedures/Other
- Avoid anoscopy/sigmoidoscopy initially unless necessary for other diagnoses or chronic fissures.
- Due to pain, some patients may require exam under anesthesia in order to confirm the diagnosis.

TREATMENT
The goal of treatment is to avoid repeated tearing of the anal mucosa with resultant spasm of the internal anal sphincter by decreasing the patient’s high sphincter tone and addressing its underlying cause.

GENERAL MEASURES
- Wash area gently with warm water; consume high-fiber diet, increase fluids, add daily fiber supplement; avoid constipation, maintain healthy weight.
Medical therapy for chronic fissures usually initiated in a stepwise manner when needed: topical nitrates, topical calcium channel blockers, botulinum toxin injections

**MEDICATION**

**First Line**

Acute fissures—50% will heal spontaneously with supportive measures (1)[B].

- Stool softeners (docusate) orally daily
- Osmotic laxatives orally daily as needed (polyethylene glycol)
- Fiber supplements (e.g., psyllium, methylcellulose, inulin) orally daily and increase fluid intake
- Topical analgesics (2% lidocaine gel or 3% cream) 2 to 3 times daily for pain control
- Topical lubricants/emollients (Balneol lotion, glycerin ointment, petroleum jelly) for comfort with defecation
- Topical hydrocortisone 1% cream short term for inflammation/pruritus
- Sitz baths (sit in plain warm-hot water bath for 10 to 20 minutes) 2 to 3 times daily after bowel movements

**Second Line**

Chronic fissures—will not heal without treatment, due to persistent internal sphincter spasm and ischemia (2)[A]:

- Chemical sphincterotomy
  - Topical nitroglycerin 0.2–0.4% ointment applied BID; nitroglycerin 0.4% ointment available commercially (Rectiv): marginally but significantly better than placebo in healing (48.6% vs. 37%); late recurrence common (50%) (2)[B]; reduces resting anal pressure through the release of nitric oxide. Headache, hypotension, dizziness are major side effects (20–30%).
  - Topical calcium channel blockers (nifedipine 0.2–0.3% gel, diltiazem 2% ointment), applied 2 to 4 times per day, relax the internal sphincter muscle, thereby reducing the resting anal pressure no better than nitrates for healing but fewer side effects consider as first-line treatment (1)[A]. Oral calcium channel blockers confer lower healing rates, more side effects, and equal rates of recurrence (3)[A].
  - Botulinum toxin 4 mL (20 units) injected into the internal sphincter muscle: no better than topical nitrates for healing but fewer side effects; inhibits the release of acetylcholine from nerve endings to inhibit muscle spasm (4)[B]

** ISSUES FOR REFERRAL**

- Late recurrence is common (50%) particularly if the underlying issue remains untreated (constipation, irritable bowel).
- Medical therapy usually tried for 90 to 120 days prior to colorectal surgery referral. Select patients with chronic fissure may be referred directly for surgical therapy due to proven superior healing rates (1)[A].

**ADDITIONAL THERAPIES**

Anococcygeal support (modified toilet seat) may offer some advantage in chronic fissures to avoid surgery.

**SURGERY/OTHER PROCEDURES**

- Surgery typically reserved for failure of medical therapy
Lateral internal sphincterotomy (LIS) involves division of the internal sphincter muscle and is the surgical procedure of choice (95% healing) (1)[A].

- Risk for fecal or flatus incontinence: up to 45% short term, up to 6–8% long term
- Open and closed techniques have similar results and are equally acceptable (1)[A].
- May be repeated for recurrent fissures with similar outcomes (1)[C]
- Not typically performed on women of childbearing potential due to increased risk of fecal incontinence with or without subsequent obstetrical injury (1)

Anocutaneous flap safe alternative to LIS in patients without anal hypertonia with less incontinence but lower healing rates (1)[B]

Botulinum toxin injections also first-line treatment; less effective (60–80% healing) than surgery but fewer complications (4)[C]

- Risk for fecal or flatus incontinence: 18% short term, no long term
- May be repeated as needed with same efficacy; lower doses as effective as higher doses with lower rates of complications including incontinence and recurrence (5)[A]
- Higher doses combined with fissurectomy may be as effective as surgical sphincterotomy (6)[C].

Controlled pneumatic balloon dilation may be used by gastroenterologists if surgical referral not available; should not be used first line as benefits are not well documented. Uncontrolled manual dilation is no longer recommended (5)[C].

**ONGOING CARE**

**DIET**
High fiber (>25 g/day; augment with daily fiber supplements); increase fluid intake, decrease caffeine

**PATIENT EDUCATION**
- Avoid prolonged sitting or straining during bowel movements; drink plenty of fluids; avoid constipation; lose weight if obese.
- Avoid use of triple antibiotic ointment and long-term use of steroid creams to anal area.
- Use a finger cot or glove when applying nitroglycerin ointment, and apply first dose before bedtime to minimize side effects.
- Topical medications should be applied directly to anal verge; no need to insert rectally.
- Alternative medicine therapies (hibiscus extract, clove oil, anal self-massage) need further study before they can be recommended as first-line treatment.

**PROGNOSIS**
Most acute fissures heal within 6 weeks with conservative therapy. Medical therapy is less likely to be successful for chronic anal fissures (40% failure rate) but should remain first-line treatment.

**COMPLICATIONS**
- Chronic fissure is a complication of nonhealing acute fissure.
- Recurrence is a common complication especially when underlying cause is not addressed.
- Abscess and fistula formation are less common complications.
- Fecal and flatus incontinence are primarily associated with surgery (5–45% postop), which may become permanent (up to 8% long term, primarily to flatus).
REFERENCES

ADDITIONAL READING

CODES

ICD10
- K60.2 Anal fissure, unspecified
- K60.0 Acute anal fissure
- K60.1 Chronic anal fissure

CLINICAL PEARLS

- Avoid anoscopy or sigmoidoscopy initially unless necessary for other diagnoses.
- Best chance to prevent recurrence is to treat the underlying cause (e.g., chronic constipation).
- No medical therapy approaches the cure rate of surgery for chronic fissure.
ANEMIA, APLASTIC
Muthalagu Ramanathan, MD

BASICS
DESCRIPTION
- Pancytopenia due to hypocellular bone marrow without the presence of infiltrates or fibrosis; classified as acquired (much more common) and congenital
- Acquired aplastic anemia: insidious onset; due to exogenous insult triggering an autoimmune reaction; often responsive to immunosuppression
- Congenital forms: rare, mostly present in childhood (exception is atypical presentation of Fanconi syndrome in adults; 30s for males and 40s for females)
- The occurrence of specific mutations in genes of the telomere complex in acquired aplastic anemia has blurred the distinction between the congenital and acquired forms.
- System(s) affected: heme/lymphatic/immunologic
- Synonym(s): hypoplastic anemia; panmyelophthisis; refractory anemia; aleukia hemorrhagica; toxic paralytic anemia

ALERT
- Early intervention for aplastic anemia greatly improves the chances of treatment success.
- Hematopoietic growth factors require close monitoring in newly diagnosed patients.

Geriatric Considerations
The elderly are often exposed to large numbers of drugs and therefore may be more susceptible to acquired aplastic anemia.

Pediatric Considerations
- Congenital forms of aplastic anemia require different treatment regimens than acquired forms.
- Acquired aplastic anemia is seen in children exposed to ionizing radiation or treated with cytotoxic chemotherapeutic agents.

Pregnancy Considerations
- Pregnancy is a real but rare cause of aplastic anemia. Symptoms may resolve after delivery and with termination.
- Complications in pregnancy can occur from low platelet counts and paroxysmal nocturnal hemoglobinurias-associated aplastic anemia.

EPIDEMIOLOGY
- Predominant age: biphasic 15 to 25 years (more common) and >60 years
- Predominant sex: male = female

Incidence
- 2 to 3 new cases per million per year in Europe and North America
- The incidence is 3-fold higher in Thailand and China versus the Western world.

ETIOLOGY AND PATHOPHYSIOLOGY
- Idiopathic (~70% of the cases)
- Drugs: phenylbutazone, chloramphenicol, sulfonamides, gold, cytotoxic drugs, antiepileptics (felbamate, carbamazepine, valproic acid, phenytoin)
- Viral: HIV, Epstein-Barr virus (EBV), nontypeable postinfectious hepatitis (not A, B, or C), parvovirus B19 (mostly in the immunocompromised), atypical mycobacterium
- Toxic exposure (benzene, pesticides, arsenic)
- Radiation exposure
- Immune disorders (systemic lupus erythematosus, eosinophilic fasciitis, graft versus host disease)
- Pregnancy (rare)
- Congenital (Fanconi anemia, dyskeratosis congenita, Shwachman-Diamond syndrome, amegakaryocytic thrombocytopenia)
- The immune hypothesis: activation of T cells with associated cytokine production leading to destruction or injury of hematopoietic stem cells. This leads to a hypocellular bone marrow without marrow fibrosis.
- The activation of T cells likely occurs because of both genetic and environmental factors. Exposure to specific environmental precipitants, diverse host, genetic risk factors, and individual differences in characteristics of immune response likely account for variations in its clinical manifestations and patterns of responsiveness to treatment.
- Telomerase deficiency leads to short telomeres. This leads to impaired regenerative capacity and hence a reduction in marrow progenitors and qualitative deficiency in the repair capacity of hematopoietic tissue.
- Reduction of natural killer cells in the bone marrow
- A somatic mutation of the PIGA gene underlies the clonal disease paroxysmal nocturnal hemoglobinuria (PNH): There is direct evidence that the expansion of the PIGA mutant clone results from Darwinian selection exerted by a glycosylphosphatidylinositol (GPI)-specific autoimmune attack (1).

**Genetics**
- Telomerase mutations found in a small number of patients with acquired and congenital forms. These mutations render carriers more susceptible to environmental insults.
- Mutations in genes called TERC and TERT were found in pedigrees of adults with acquired aplastic anemia who lacked the physical abnormalities or a family history typical of inherited forms of bone marrow failure. These genes encode for the RNA component of telomerase.
- HLA-DR2 incidence in aplastic anemia is twice that in the normal population.

**RISK FACTORS**
- Treatment with high-dose radiation or chemotherapy
- Exposure to toxic chemicals
- Use of certain medications
- Certain blood diseases, autoimmune disorders, and serious infections
- Tumors of thymus (red cell aplasia)
- Pregnancy, rarely

**GENERAL PREVENTION**
- Avoid possible toxic industrial agents.
- Use safety measures when working with radiation.
DIAGNOSIS

HISTORY
- Solvent and radiation history; family, environmental, travel, and infectious disease history
- Patients are often asymptomatic but may have frequent infections, fatigue, shortness of breath, headache, or bleeding/bruising.

PHYSICAL EXAM
- Mucosal hemorrhage, petechiae
- Pallor
- Fever
- Hemorrhage, menorrhagia, occult stool blood, melena, epistaxis
- Dyspnea
- Palpitations
- Progressive weakness
- Retinal flame hemorrhages
- Systolic ejection murmur
- Weight loss
- Signs of congenital aplastic anemia
  - Short stature
  - Microcephaly
  - Nail dystrophy
  - Abnormal thumbs
  - Oral leukoplakia
  - Hyperpigmentation (café au lait spots) or hypopigmentation

DIFFERENTIAL DIAGNOSIS
Includes other causes of bone marrow failure and pancytopenia
- Hypoplastic myelodysplastic syndrome (MDS)
- Marrow replacement
  - Acute lymphoblastic leukemia
  - Lymphoma
  - Hairy cell leukemia (increased reticulin and infiltration of hairy cells)
  - Large granular lymphocyte leukemia
  - Fibrosis
- Megaloblastic hematopoiesis
  - Folate deficiency
  - Vitamin B₁₂ deficiency
- Paroxysmal nocturnal hemoglobinuria, hemolytic anemia (dark urine), pancytopenia, and venous thrombosis (classically hepatic veins)
- Systemic lupus erythematosus
- Prolonged starvation or anorexia nervosa (Bone marrow is gelatinous with loss of fat cells and increased ground substance.)
- Transient erythroblastopenia of childhood
- Drug-induced agranulocytosis that may be reversible on withdrawal of drug
- Overwhelming infection
- HIV with myelodysplasia
- Viral hemophagocytic syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

Screening tests to exclude other etiologies
- Complete blood count (CBC) and absolute reticulocyte count
- Blood smear exam
- Cytogenetic studies to exclude MDS and of peripheral lymphocytes if <35 years of age to exclude Fanconi anemia
- Liver function test
- Viral serology: hepatitis A, B, C; EBV; cytomegalovirus (CMV); HIV
- Vitamin B₁₂ and folate levels
- Autoantibody screening antinuclear antibody (ANA) and anti-DNA
- Flow cytometry looking for GPI, negative neutrophils, and red blood cells (RBCs) for detecting paroxysmal nocturnal hemoglobinuria
- Fetal hemoglobin in children
- Red cell adenosine deaminase (pure red cell aplasia)
- Cytogenetic analysis of bone marrow

**Initial Tests (lab, imaging)**
- CBC: pancytopenia, anemia (usually normocytic), leukopenia, neutropenia, thrombocytopenia
- Decreased absolute number of reticulocytes
- Increased serum iron secondary to transfusion
- Normal total iron-binding capacity (TIBC)
- High mean corpuscular volume (MCV) >104
- CD34+ cells decreased in blood and marrow
- Urinalysis: hematuria
- Abnormal liver function tests (hepatitis)
- Increased fetal hemoglobin (Fanconi)
- Increased chromosomal breaks under specialized conditions (Fanconi)
- Molecular determination of abnormal gene (Fanconi)
- CT of thymus region if thymoma-associated RBC aplasia suspected
- Radiographs of radius and thumbs (if congenital anemia suspected)
- Renal ultrasound (to rule out congenital anemia or malignant hematologic disorder)
- Chest x-ray to exclude infections such as mycobacterial infection

**Diagnostic Procedures/Other**

Bone marrow aspiration and biopsy

**Test Interpretation**
- Normochromic RBC
- Bone marrow
  - Decreased cellularity (<10%): no fibrosis, no malignant cells or dysplastic cells seen
  - Decreased megakaryocytes
  - Decreased myeloid precursors
  - Decreased erythroid precursors
  - Prominent fat spaces and marrow stroma, polyclonal plasma cells
TREATMENT

Early treatment increases the chance of success. Two major options: immunosuppressive therapy and hematopoietic stem cell transplantation. Treatment decisions are based on age of the patient, severity of disease, and availability of a human leukocyte antigen (HLA)–matched sibling donor for transplantation.

GENERAL MEASURES

- Supportive measures: RBC and platelet transfusions. Use only irradiated leukocyte-reduced or CMV-negative blood especially if patient is a candidate for hematopoietic stem cell transplantation.
- Antibiotics, antifungals, antivirals when appropriate, especially if absolute neutrophil count (ANC) <100 cells/μL.
- Oxygen therapy for severe anemia
- Good oral hygiene
- Control menorrhagia with norethisterone or oral contraceptive pills.
- Avoid/discontinue causative agents/isolation if necessary.
- HLA testing on all patients and their immediate families
- Transfusion support (judiciously prescribed RBCs for severe anemia; platelets for severe thrombocytopenia)
  - Transfuse when
    - Hb <7 g/dL or if Hb <8 g/dL and symptomatic ± congestive heart failure (CHF)
    - Platelet count is <10 × 10^9 or if <20 × 10^9 with fever/bleeding

MEDICATION

First Line

- Corticosteroids (methylprednisolone) are often given with immunosuppressive regimens.
- Immunosuppressive therapy
  - A combination of antithymocyte globulin (ATG) plus cyclosporine. ATG eliminates lymphocytes, and cyclosporine blocks T-cell function.
- ATG
  - Horse serum containing polyclonal antibodies against human T cells
  - First-choice treatment for patients >40 years of age and for younger patients without a compatible donor. Consider in patients 30 to 40 years of age.
  - May be used as a single agent but has better response in combination with cyclosporine
- Cyclosporine following initial ATG therapy for minimum of 6 months
  - Monitor through blood levels. Normal values for assays vary.
  - Note: Relapses may occur after the initial response to the immunosuppressive therapy if cyclosporine is discontinued too early. Restarting cyclosporine can lead to a response in up to 25% of patients.
- Granulocyte-colony stimulating factor (G-CSF)
  - May be used in conjunction with ATG and cyclosporine
  - Shows faster neutrophil recovery, but survival is not improved
  - Treatment is costly and is disputed in two randomized trials.
- Stem cell transplant: matched sibling allogeneic stem cell transplant for age <20 years and ANC <500 or age 20 to 40 years and ANC <200
Second Line
- Rabbit ATG + cyclosporine
- Campath
- Androgen such as danazol can be used in a subset of patients who have anemia as a predominant feature.
- Matched unrelated donor stem cell transplant
- Eltrombopag
- In trials: thrombopoietin (TPO) receptor agonists
- Cytoxan 50 mg/kg daily for 4 days can be used for refractory disease

ISSUES FOR REFERRAL
Early referral is recommended to avoid infectious complications

SURGERY/OTHER PROCEDURES
- First-line hematopoietic stem cell transplantation is recommended for patients with an HLA-identical donor and severe aplastic anemia when age <20 years and ANC <500 or age 20 to 40 years and ANC <200. Consider in patients 40 to 50 years of age in good general medical condition.
- Patients >40 years of age have higher rates of graft versus host disease and graft rejection. Individuals with potentially poor-prognosis mutations such as mutations in ASXL1 or DNMT3A tend to have worse outcomes from IST, and we may be more likely to suggest HCT for these individuals.
- Unrelated donor transplants should be considered for patients age <40 years without HLA-matched sibling donor who fail first-line immunosuppressive therapy.
- Thymectomy for thymoma

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
If neutropenic, use antiseptic mouthwash such as chlorhexidine.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
patients need to be monitored closely for infection and transfusion support while on immunosuppression

DIET
If neutropenic, avoid foods that can expose patient to bacteria, such as uncooked foods. https://www.lls.org/managing-your-cancer/diet-guidelines-for-immunosuppressed-patients

PATIENT EDUCATION
- Stay away from people who are sick; avoid large crowds.
- Wash your hands often.
- Brush and floss your teeth; get regular dental care to reduce risk of infections.
- Pneumonia vaccine and annual flu shot
PROGNOSIS

- Hematopoietic stem cell transplantation with HLA-matched sibling
  - Age <16 years, 91% at 5 years
  - Age >16 years, 70–80% at 5 years
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years

COMPLICATIONS

- Infection (fungal, sepsis)
- Graft versus host disease in bone marrow transplant recipients (acute 18%; chronic 26%)
- Side effects of immunosuppressant medications
- Hemorrhage
- Transfusion hemosiderosis
- Transfusion hepatitis
- Heart failure
- Development of secondary cancer: leukemia or myelodysplasia (15–19% risk at 6 to 10 years)
- Refractory pancytopenia

REFERENCES

SEE ALSO

- Lupus Erythematosus, Systemic (SLE); Myelodysplastic Syndromes (MDS)
- Algorithm: Anemia

CODES

ICD10

- D61 Other aplastic anemias and other bone marrow failure syndromes
- D61.0 Constitutional aplastic anemia
- D61.01 Constitutional (pure) red blood cell aplasia

CLINICAL PEARLS

- Acquired aplastic anemia has an insidious onset and is caused by an exogenous insult triggering an autoimmune reaction. This form is usually responsive to immunosuppressive therapy.
- Etiology includes: Idiopathic (<70% of the cases), Drugs: phenylbutazone, chloramphenicol, sulfonamides, gold, cytotoxic drugs, antiepileptics (felbamate, carbamazepine, valproic acid, phenytoin), Viral: HIV, Epstein-Barr virus (EBV), nontypeable postinfectious hepatitis (not A, B, or C), parvovirus B19 (mostly in the immunocompromised), atypical mycobacterium, toxic exposure (benzene, pesticides, arsenic), radiation exposure
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years
ANEMIA, CHRONIC DISEASE
Christopher Lin-Brande • Peter Scott

BASICS
DESCRIPTION
- Otherwise known as anemia of chronic inflammation
- During chronic systemic infection, inflammation, or malignancy, the production of proinflammatory mediators causes inhibition of erythropoiesis as well as the imbalance in iron homeostasis (1).
- Anemia of chronic disease (ACD) is characterized as a normocytic, normochromic, hypoproliferative anemia and classically has low serum iron levels, elevated ferritin levels, and elevated total iron-binding capacity (TIBC) (1,2).
- Anemia is typically mild to moderate with hemoglobin (Hgb) rarely <8 g/dL.

EPIDEMIOLOGY
Prevalence
ACD is the second most common anemia after iron deficiency anemia (IDA) due to the aging population and the high prevalence of chronic infections and inflammatory disorders in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- Production of red blood cells is decreased as a result of functional iron deficiency.
- In general, the severity of the anemia will correspond with the severity of the underlying disease (1).
- Proinflammatory cytokines such as interleukins (IL), tumor necrosis factor (TNF), bone morphogenic proteins (BMP), and interferons (IFN) create changes in iron homeostasis in several ways (1):
  - Dysregulating iron homeostasis
  - Diminishing proliferation as well as differentiation of red blood cell progenitor cells
  - Blunting the erythropoietic response
  - Increasing erythrocyte phagocytosis and apoptosis
- Iron overload and the proinflammatory cytokines IL-1, IL-6, and BMP6 increase the production of the iron-regulating hormone hepcidin in hepatocytes, macrophages, and enterocytes (1).
  - Hepcidin binds to ferroportin causing internalization and degradation, preventing efflux of iron from stores in macrophages and hepatocytes, stopping iron absorption by duodenal enterocytes.
    - This results in low serum iron levels and inhibited erythropoiesis known as iron-restricted erythropoiesis.
    - As a result, iron delivery to erythroid progenitor cells within bone marrow is reduced and erythropoiesis is diminished, causing anemia.
- Erythropoietin (EPO) production and the response to EPO by erythroid bone marrow is suppressed by proinflammatory cytokines such as IL-1, TNF-α, and IFN-γ (1).
- Inflammatory cytokines may also cause erythrophagocytosis and oxidative damage, reducing
COMMONLY ASSOCIATED CONDITIONS

- Chronic systemic diseases
  - Rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), sarcoidosis, temporal arteritis, inflammatory bowel disease (IBD), systemic inflammatory response syndrome (SIRS)
- Hepatic disease or failure
- Congestive heart failure or coronary artery disease
- Chronic kidney disease (CKD)
- Acute or chronic infections
  - Viral
    - HIV, hepatitis C virus
  - Bacterial
    - Abscess, subacute bacterial endocarditis, tuberculosis, osteomyelitis
  - Fungal
  - Parasitic
- Malignancies
- Cytokine dysregulation (anemia of aging)
- Hypometabolic states
  - Protein malnutrition, thyroid disease, panhypopituitarism, diabetes mellitus, Addison disease

DIAGNOSIS

HISTORY

- ACD is often discovered incidentally on routine complete blood count with differential.
- ACD presents with the underlying causative infectious, inflammatory, or malignant process without any source of occult bleeding; often, patients will have mild and vague anemia symptoms, such as fatigue, light-headedness, and palpitations (1).
- Those with a cardiovascular condition may experience symptoms of angina, shortness of breath, and reduced exercise capacity with even a moderate Hgb level (10 to 11 g/dL).

PHYSICAL EXAM

Physical exam findings are associated with the underlying condition.

DIFFERENTIAL DIAGNOSIS

- IDA
- Anemia of CKD
- Drug-induced marrow suppression or hemolysis
- Endocrine disorders
- Thalassemia
- Sideroblastic anemia
- Dilutional anemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Hgb/Hct, mean corpuscular volume (MCV), reticulocyte count, ferritin, B₁₂/folate, serum iron, TIBC
- Hgb (1)
  - Typically, <13 g/dL in males or <12 g/dL in females
  - An Hgb of <8 g/dL suggests a concurrent secondary cause for the anemia.
- MCV
  - Usually normal (80 to 100 fL), but microcytosis may be present with concurrent iron deficiency or long-standing disease (<25% of cases)
- RBC morphology
  - Normocytic and normochromic
  - Increased protoporphyrin levels
- Serum ferritin
  - Nonspecific acute phase reactant
  - Normal or slightly elevated (30 to 200 μg/L)
  - In CKD, ferritin can reach 800 μg/L.
  - Serum ferritin levels <30 μg/L suggests coexisting iron deficiency.
- Serum iron levels
  - Low due to increased retention and decreased release from stores
  - <50 mcg/dL
- TIBC
  - Extremely low
  - <300 mcg/dL
- Absolute reticulocyte count
  - Inappropriately low (reticulocyte index, 20,000 to 25,000/mL) due to reduced erythropoiesis
- Serum B₁₂ and folate
  - Diminished due to decreased absorption or lacking in diet

**Diagnostic Procedures/Other**
- Traditional gold standard: bone marrow biopsy with Prussian blue stainable iron combined with anemia, hypoferremia, and low TSAT (1)
  - Staining is qualitative and may not be accurate.
- Reticulocyte Hgb concentration <28 pg (2)
- Soluble transferrin receptor (sTfR) and the sTfR/log ferritin index
  - Ratio reflects erythropoiesis within bone marrow and differentiates among ACD, IDA, and ACD+IDA.
  - However, sTfR alone may have greater clinical value than the sTfR index because
transferrin is not affected by chronic disease/inflammation, unlike ferritin.

- Functional test: supplemental iron increase H/H in IDA and little effect on ACD
- Although a known cause of anemia may be present, iron, B_{12}, and folate deficiencies should be ruled out.

**TREATMENT**

**GENERAL MEASURES**

- Primary management should focus on the underlying cause of ACD (1).
  - Treatment of the primary disease will generally restore Hgb back to baseline.
- In cases where primary treatment is not possible (e.g., terminal cancer, end-stage renal disease), additional treatment can be considered.
  - The two main forms of treatment are erythropoietin-stimulating agents (ESAs) and transfusions.
  - ACD is frequently responsive to ESAs (epoetin-α, darbepoetin) in pharmacologic doses (3).
  - Replete iron to maximize ESA effectiveness.
  - Transfusion should only be initiated in severe anemia or acute symptoms.
- Currently, no target Hgb exists, but treatment to Hgb >13 g/dL is associated with adverse outcomes (1).
- Coexisting B_{12} or folate deficiency should be considered and corrected in severe cases of anemia.
  - Reduced dietary intake of nutrients is common among patients who are chronically ill.
  - Patients who regularly undergo hemodialysis will often be deficient in during treatment.

**MEDICATION**

- ESAs
  - Specifically approved for CKD, but there is evidence that they may also have applications in RA, IBD, HIV, and cancer
  - Indication for ESA therapy is an Hgb <10 g/dL (3)[C].
  - ESAs do not improve symptoms or outcomes in mild anemia of CHF.
  - Do not use in certain cancers: breast, cervical, head and neck, lymphoid, and non–small-cell lung cancers. Do not administer to patients with active malignancy not receiving curative therapy.
- Epoetin-α (1,3,4)
  - Indications
    - Hgb <10 g/dL
    - Fatigue or exertional intolerance
    - CKD (estimated glomerular filtration rate <60 mL/min)
    - Anemia due to IBD, RA, hepatitis C
    - Chemotherapy in patients with specific malignancies (palliative therapy)
  - Dosing and schedule
    - Lowest effective dose to maintain an Hgb level generally between 10 and 12 g/dL (1,3,4)
    - CKD associated: Start 50 to 100 U/kg SC/IV 3 times per week.
    - Patients with cancer who are undergoing chemotherapy: 150 U/kg SQ 3 times per week or 40,000 U once a week
  - Adverse effects:
Increased risk of cardiovascular complications, mortality, and thromboembolism
- Pure red cell aplasia (decrease in Hgb, low reticulocyte count, normal WBC and platelets)
- Risk of tumor progression in certain cancer patients

**Darbepoetin-α**
- Long-acting, molecularly modified EPO preparation with a half-life 3 to 4 times longer than recombinant human EPO, reducing the frequency of injections to weekly or biweekly
- Dosing and schedule
  - Administer SC/IV q1–2wk; hold if Hgb >12 g/dL; IV route is preferred in hemodialysis patients.
- Adverse effects
  - Similar to EPO

**Epoetin-α** or **darbepoetin-α** dose adjustments
- Follow FDA-approved labeling.
- Treatment beyond 6 to 8 weeks without appropriate rise of Hgb (>1 to 2 g/dL) is not recommended.

**ADDITIONAL THERAPIES**

**Iron (3)**
- Indications
  - Coexisting iron deficiency
  - Resistance to EPO
- Forms
  - Oral: ferrous sulfate. Poorly tolerated (GI side effects); incomplete absorption (due to hepcidin)
  - Intravenous: ferric gluconate, iron sucrose, iron dextran (potential allergic and anaphylactoid reactions), ferumoxytol
- Adverse effects
  - May stimulate hepcidin production and exacerbate iron restriction
- Benefits
  - Relatively safe
  - Inexpensive
  - May decrease ESA requirements (DRIVE study)

**Transfusions**
- 1 to 2 U packed red blood cells (1)
- Indications
  - Life-threatening/severe anemia: A “restrictive threshold” of Hgb 7 to 8 g/dL to guide transfusion in asymptomatic patients should be used (5)[A].
  - Patients with underlying cardiac or pulmonary disease, active ACS, elderly patients, or patients with acute bleeding or hemorrhagic shock may require transfusion at Hgb of higher threshold (>10 g/dL).
  - Symptomatic anemia (chest pain, shortness of breath, reduced exercise capacity) and/or ECG changes
  - Lack of response to medical therapy
- Possible adverse effects
  - Infection (HIV, hepatitis)
  - Volume overload
  - Transfusion reaction
Specific benefits
- Rapid correction of anemia
- When an infection occurs during EPO therapy, it is best to cease EPO therapy and rely on transfusion therapy instead until the infection is properly treated.

Future directions (1)
- Antihepcidin antibodies, hepcidin-production inhibitors
- Anti-BMP, anti–IL-6 antibodies
- Ferroportin stabilizers
- Vitamin D (lowers hepcidin)
- Heparin (impairs hepcidin transcription)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Referral to a hematologist is not always warranted.

Patient Monitoring
- Hgb should not be increased >11 to 12 g/dL because normalization of Hgb has been associated with higher mortality (4).
- Baseline and periodic monitoring of transferrin saturation and ferritin levels every 3 months may be of value (3).

PATIENT EDUCATION
Patients receiving medical therapy should be advised about the following possible risks:
- Mortality, cardiovascular complications, thromboembolism, progression of cancer

PROGNOSIS
ACD does not typically progress.

COMPLICATIONS
- Adverse effects of ACD:
  - Mortality
  - Cardiovascular complications
  - Symptoms affecting daily life
- Adverse effects of ESAs:
  - Heightened risk of mortality and/or cardiovascular complications in CKD patients
  - Heightened risk of mortality and/or tumor progression in cancer patients
  - Elevated risk of thromboembolism

REFERENCES

ADDITIONAL READING

SEE ALSO

- Anemia, Iron Deficiency; Iron Studies; Microcytic Anemia

CODES

ICD10

- D63.8 Anemia in other chronic diseases classified elsewhere
- D63.0 Anemia in neoplastic disease
- D63.1 Anemia in chronic kidney disease

CLINICAL PEARLS

- ACD is the second most common anemia seen clinically.
- One of the most common diagnostic problems is making the distinction between ACD, IDA, and combined ACD + IDA.
  - Iron level is usually nondiagnostic.
  - Use markers such as transferrin/TIBC, TSAT, and ferritin to distinguish. New markers are under development (hepcidin, sTfR, sTfR index).
- IV iron should be given to all patients treated with ESAs.
- Hgb should be kept in low to normal range.
ANEMIA, IRON DEFICIENCY
Deborah R. Erlich, MD, MMedEd, FAAFP

BASICS

DESCRIPTION

- Low serum iron associated with low hemoglobin (Hgb) or microcytic, hypochromic red blood cells (RBCs)
- Because normal Hgb varies with age and sex, anemia is defined as Hgb level 2 standard deviations below normal for age and sex (1).
- Onset acute (rapid blood loss) or chronic (slow blood loss, deficient iron intake, or poor absorption)
- Both low Hgb per RBC and fewer RBC in total lead to blood oxygen deficiency, which can have serious systemic consequences.
- System(s) affected: hematologic, lymphatic, immunologic, cardiac, and gastrointestinal systems

Geriatric Considerations
Iron deficiency anemia (IDA) is associated with increased hospitalization, morbidity, and mortality in older adults (2).

Pediatric Considerations
Risks for IDA in children include low birth weight, history of prematurity, lead exposure, low income status, and immigrant status. Additionally, infants who drink cow’s milk before 12 months of age have a higher risk for IDA. The U.S. Preventive Services Task Force (USPSTF) did not find sufficient evidence for screening low-risk infants, the Centers for Disease Control (CDC) recommends screening high-risk infants at 6 to 12 months, and the AAP recommends universal screening at 12 months (1)[B].

Pregnancy Considerations
- The USPSTF did not find sufficient evidence for screening pregnant women for IDA; the CDC recommends screening women for anemia at the first prenatal visit and giving low-dose iron to all pregnant women, whereas the American College of Obstetricians and Gynecologists (ACOG) recommends screening all pregnant women for IDA and treating those with IDA.
- Iron supplements are recommended during pregnancy to improve maternal hematologic indexes, although significant clinical outcomes have not been proven (3)[A].

EPIDEMIOLOGY

- Iron deficiency is the most common nutritional deficiency in the world (4,5), and IDA is the most common cause of anemia (50%) (4).
- Predominant age: all ages but especially toddlers and menstruating and pregnant women
- Predominant sex: female
- Predominant race: Mexican American and black females (4)
- Common in both developing and developed countries

Incidence
- Adults: men 2%, women 15–20% annually
- Infants and toddlers: 3–5% annually
- Pregnant patients: may be as high as 20% (1)

**Prevalence**
2 billion people worldwide (5)
- Infants and children age <12 years: 4–7%
- Men: 2–5%
- Menstruating women: 30% (5)

**ETIOLOGY AND PATHOPHYSIOLOGY**
Depletion of iron stores leads to decrease in both reticulocyte count and production of Hgb.

Causes:
- Blood loss (menses, GI bleeding, trauma)
- Poor iron intake
- Poor iron absorption (e.g., atrophic gastritis, postgastrectomy, celiac disease)
- Increased demand for iron (e.g., infancy, adolescence, pregnancy, breastfeeding)

**RISK FACTORS**
- Premenopausal woman
- Frequent blood donor
- Pregnancy/lactation, young maternal age
- Strict vegan diet
- Use of NSAIDs
- Hospitalized with frequent blood draws
- Living in or visiting countries with endemic hookworm infection

**GENERAL PREVENTION**
- Consider screening asymptomatic pregnant women and high-risk children at 1 year of age (guidelines vary) (1)[C].
- Supplementation in asymptomatic children aged 6 to 12 months if at risk for IDA (e.g., malnutrition, abuse, cow’s milk <12 months) (1,3)
- Iron- and vitamin C–rich diet for menstruating women
- Iron 30 mg/day for asymptomatic pregnant women (3)

**COMMONLY ASSOCIATED CONDITIONS**
- GI tract malignancy, peptic ulcer disease (PUD), Helicobacter pylori infection, irritable bowel disease
- Hookworm or other parasitic infestations
- Hypermetrorrhagia
- Pregnancy
- Obesity treated with gastric bypass surgery
- Malnutrition
- Medications such as NSAIDs or antacids

**DIAGNOSIS**
HISTORY
- Asymptomatic in most cases
- Weakness, fatigue, and/or malaise
- Exertional dyspnea
- Angina with coronary artery disease
- Headaches or inability to concentrate
- Melena
- Pica

PHYSICAL EXAM
- Pallor (skin, conjunctivae, sublingual)
- Tachycardia, tachypnea
- Cool extremities
- Brittle nails/hair
- Signs of heart failure

DIFFERENTIAL DIAGNOSIS
- GI bleeding (e.g., gastritis, PUD, carcinoma, varices, celiac disease)
- Chronic intravascular hemolysis (e.g., paroxysmal nocturnal hemoglobinuria, malfunctioning prosthetic valve)
- Defective iron usage (e.g., thalassemia trait, sideroblastosis, G6PD deficiency)
- Defective iron reutilization (e.g., infection, inflammation, cancer, hypothyroid, chronic diseases)
- Hypoproliferation (e.g., decreased erythropoietin from hypothyroidism, renal failure)
- Other anemias such as anemia of chronic disease, thalassemia, lead poisoning

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Test with signs and symptoms of anemia, and fully evaluate if iron deficiency is confirmed (1,5).
- Hgb (to define anemia):
  - <13 g in men and <12 g in women (5)
  - Hgb 2 standard deviations below normal for age and sex (1)
  - Patients with comorbidities (e.g., chronic hypoxemia, smokers, high altitudes) may be anemic at higher Hgb levels.
- Mean corpuscular volume (MCV): <80 Fl
  - MCV may be low normal in mild anemia or hidden by large cells (reticulocytes, macrocytes).
- Ferritin is most sensitive and specific for diagnosing iron deficiency as cause of anemia (5):
  - <15 μg/L diagnoses IDA (<30 μg/L likely) (1).
  - >100 μg/L rules out iron deficiency.
- Iron studies:
  - Decreased: ferritin, serum iron, transferrin saturation
  - Increased: total iron-binding capacity (TIBC), transferrin
- Red cell distribution width (RDW) increases with a mixed population of cells (e.g., mixed IDA and vitamin B₁₂ deficiency).
- CBC with differential, peripheral smear, reticulocyte count, and index
Peripheral smear usually shows hypochromia and microcytosis but may be normal, and reticulocyte production index is low (1).

- Consider testing for G6PD deficiency.
- Evaluate for thalassemia.
  - Very low MCV <80, elevated Hgb A2 or Hgb F, family history, and especially high or high normal RBC count
  - Microcytosis with ovalocytosis and unresponsive to iron suggests the thalassemia trait.
- IgA antiendomysial antibodies (IgA anti-EmA) and/or IgA antitissue transglutaminase (IgA anti-TTG) for celiac disease
- TSH for hypothyroidism
- An empiric trial of iron at 3 mg/kg/day may help diagnose decreased iron stores in children; reticulocytes become elevated in 7 to 10 days or Hgb increases >1 g/dL weekly, indicating iron deficiency.
- Drugs that may alter lab results:
  - Iron supplements or multivitamin–mineral preparations that contain iron
- Disorders that may alter lab results:
  - Elevated ferritin: acute inflammation, acute or chronic liver disease, Hodgkin disease, acute leukemia, solid tumors, fever, renal dialysis
  - Elevated Hgb: smoking, chronic hypoxemia, high altitude

**Diagnostic Procedures/Other**
- Stool guaiac
- Stool for ova and parasites if at risk
- Colonoscopy and endoscopy to evaluate for bleeding sites and colorectal and gastric carcinoma for:
  - Premenopausal women with negative GYN workup and/or lack of response to iron
  - Men and postmenopausal women (1)[C]
- Bone marrow aspiration rarely performed

**TREATMENT**

**GENERAL MEASURES**
- Search for underlying cause and correct.
- Avoid transfusions, except in rare cases.

**MEDICATION**
- Elemental iron 100 to 200 mg/day for adults (whether pregnant or not) (3,5)[C]
- Elemental iron 3 to 6 mg/kg/day for children (5)
- Ferrous sulfate 325 mg TID, ferrous gluconate 300 mg 1 to 3 tablets BID–TID or ferrous fumarate 324 mg 1 tablet BID on an empty stomach 1 hour before meals (1)[C]
- Constipation will occur in ~1/4 of patients. Consider a stool softener along with iron.
  - Medications that reduce gastric acid secretion such as proton pump inhibitors and H₂ antagonists reduce iron absorption (1).
  - Special oral iron formulations (e.g., enteric-coated iron) are expensive and reduce symptoms only to the degree that they reduce the delivery of iron.
- IV iron is indicated for patients who cannot tolerate the side effects of oral replacement (e.g.,
pregnant women or patients with GI disorders) or for patients who do not sufficiently respond to oral replacement. Other indications for IV iron: bariatric surgery status, heavy uterine bleeding, malabsorption, inflammatory bowel disease, ongoing/severe losses

- Outside of the United States, IV iron is becoming first line ahead of oral iron for its superiority in efficacy and toxicity.
- IV iron formulations available in the United States:
  - Low-molecular-weight iron dextran 1,000 mg over 1 hour
  - Ferumoxytol 510 mg over 3 minutes
  - Ferric carboxymaltose 750 mg over 15 minutes
- Liquid iron preparations (used for children) can also be used in adults when tablets are not absorbed or low tolerance requires a dose reduction.
  - Continued bleeding and untreated hypothyroidism are causes for “failure to respond” to iron.
  - Formula to determine elemental iron needed: elemental iron (mg) = dose (mL) = 0.0442 (desired Hgb − observed Hgb) × LBW + (0.26 × LBW)
    o Desired Hgb = target Hgb in g/dL
    o Observed Hgb = current Hgb in g/dL
    o LBW = lean body weight in kg
    o For males: LBW = 50 kg + 2.3 kg for each inch of height >5 feet
    o For females: LBW = 45.5 kg + 2.3 kg for each inch of height >5 feet
    o Normal Hgb (males and females)
      ■ >15 kg (33 lb) . . . 14.8 g/dL
      ■ <15 kg (33 lb) . . . 12.0 g/dL
- Relative contraindications for oral iron:
  - Tetracycline
  - Allopurinol
  - Antacids
  - Penicillamine
  - Fluoroquinolones
  - Vitamin E
- Consider parenteral iron for patients with an Hgb level <6 g/dL, malabsorption, chronic kidney disease, or failure to respond to higher oral doses with concomitant vitamin C (5).
- Issues for parenteral iron formulations:
  - Give test dose for iron dextran prior to first dose to avoid anaphylaxis; ferric gluconate or iron sucrose may be safer alternative. Dimercaprol increases risk of nephrotoxicity.
  - Dosing is product dependent; refer to individual product for suggested dosing.
- Precautions
  - Iron may cause dark stools and constipation.
  - Iron overdose is highly toxic; absorption is limited to 1 to 2 mg daily (5); keep tablets and liquids out of reach of small children.
- Blood transfusion for severe acute blood loss or severely symptomatic patients (e.g., demand ischemia due to anemia). Hgb threshold varies by risk factors and clinical scenario. Pregnant women with Hgb <6 should be transfused (1)[C].

ISSUES FOR REFERRAL

- Men and postmenopausal women with IDA (Test for colon cancer.)
- Pregnant women with Hgb level <9 g/dL
Men or nonpregnant women with an Hgb level <6 g/dL
Failure to respond to a 4- to 6-week trial of oral iron

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monitor patients every 3 months after Hgb normalizes for a year and then yearly (1)[C].
- Hgb increases 1 g/dL every 3 to 4 weeks.
- Iron stores may take up to 4 weeks to correct after Hgb normalizes.

**DIET**
- Iron-rich foods include red meat; poultry; fish (all heme iron sources, best absorbed); and iron-fortified breads/cereals, lentils, beans, dark green vegetables, and raisins (all non-heme iron sources, less well absorbed) (6).
- Foods and beverages containing ascorbic acid (vitamin C) enhance iron absorption when taken simultaneously (5).
- Avoid milk or dairy products within 2 hours of iron tablet ingestion.
- Limit milk to 16 oz/day (adults).
- Limit tea, coffee, and caffeinated beverages.
- Increase fluid and dietary fiber to decrease likelihood of constipation.
- Limit foods with high levels of chemicals (phytates and polyphenols).

**PATIENT EDUCATION**

**PROGNOSIS**
- IDA can be resolved with iron therapy if the underlying cause is discovered and appropriately treated.
- Treat coexisting subclinical hypothyroidism and IDA together. Failure to treat hypothyroidism results in poor response to iron therapy.

**COMPLICATIONS**
- Hidden bleeding, particularly a bleeding malignancy
- Ischemic events or heart failure, especially in elderly
- Poor growth, failure to thrive, motor and cognitive developmental delay in children (4)

**REFERENCES**

ADDITIONAL READING

SEE ALSO

Algorithm: Anemia

CODES

ICD10

- D50.9 Iron deficiency anemia, unspecified
- D62 Acute posthemorrhagic anemia
- D50.0 Iron deficiency anemia secondary to blood loss (chronic)

CLINICAL PEARLS

- IDA due to poor dietary iron intake is the most common anemia.
- Blood loss and reduced iron stores due to poor utilization or malabsorption are risk factors for IDA.
- Premenopausal women and children are at the greatest risk for IDA.
- Cow’s milk should not be given to children aged <12 months.
* Oral iron supplementation is the standard first-line treatment for IDA.
ANEMIA, SICKLE CELL
Tipsuda Junsanto-Bahri, MD

**BASICS**

**DESCRIPTION**
- Hereditary, hemoglobinopathy marked by chronic hemolytic anemia, acute episodes of painful “crises,” and increased susceptibility to infections
- The heterozygous condition (Hb AS), sickle cell trait, is usually asymptomatic without anemia.
- Synonym(s): sickle cell disease (SCD); Hb SS disease

**Pediatric Considerations**
- Sequestration crises and hand–foot syndrome seen typically in infants/young children
- Strokes occur mainly in childhood.
- Adolescence/young adulthood:
  - Frequency of complications and organ/tissue damage increases with age.
  - Psychological complications: body image, interrupted schooling, restriction of activities; stigma of disease; low self-esteem

**Pregnancy Considerations**
- Complicated, especially during 3rd trimester and delivery
  - Fetal mortality 35–40%. Fetal survival is >90% if the fetus reaches the 3rd trimester.
  - High prevalence of small for gestational age (SGA) babies
- Increased risk of thrombosis, preterm delivery, pain, toxemia, infection, pulmonary infarction, and phlebitis
- Partial exchange transfusion in 3rd trimester may reduce maternal morbidity and fetal mortality but is controversial.
- Chronic transfusions have been effective in diminishing pain episodes in pregnant women. However, this method should be used with caution due to risk of alloimmunization.

**EPIDEMIOLOGY**

**Prevalence**
- ~90,000 Americans have sickle cell anemia (SCA), and 3.5 million people in the United States have sickle cell trait.
- The condition affects mainly people of African descent. Hispanic, Middle Eastern, and Asian Indian ancestry may also be affected.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Hemoglobin S (HbS) results from the substitution of the amino acid valine for glutamic acid at the sixth position of the β-globin chain.
- HbS polymerizes in the red blood cell (RBC) in the deoxygenated state, resulting in RBC sickling.
- Sickle RBCs are inflexible, causing increased blood viscosity, stasis, obstruction of small arterioles and capillaries, and ischemia.
- Chronic anemia; crises:
  - Vaso-occlusive crisis: tissue ischemia and necrosis; progressive organ failure/tissue damage
from repeated episodes
– Hand–foot syndrome: Vessel occlusion/ischemia affects small blood vessels in hands or feet.
– Aplastic crisis: suppression of RBC production by severe infection (e.g., parvoviral and other viral infections)
– Suppression of RBC production
– Hyperhemolytic crisis: accelerated hemolysis with reticulocytosis; increased RBC fragility/shortened lifespan
– Sequestration crisis: splenic sequestration of blood (only in young children as spleen is later lost to autoinfarction)

Susceptibility to infection: impaired/absent splenic function leading to decreased ability to clear infection; defect in alternate pathway of complement activation

Increased red cell destruction causes decreased hemoglobin levels and results in anemia and fatigue.

Sickled cells exhibit increased adhesion and decreased ability to maneuver through small vessels, leading to vaso-occlusion.

Genetics
– Autosomal recessive. Homozygous condition, Hb SS; heterozygous condition, Hb AS
– The heterozygote condition can also be combined with other hemoglobinopathies: Sickle cell hemoglobin C (HbSC) disease and Sβ+ thalassemia are clinically similar to the heterozygous condition, whereas Sβ thalassemia is clinically similar to the homozygous condition.

RISK FACTORS
– Vaso-occlusive crisis (“painful crisis”): hypoxia, dehydration, fever, infection, acidosis, cold, anesthesia, strenuous physical exercise, smoking
– Aplastic crisis (suppression of RBC production): severe infections, human parvovirus B19 infection, folic acid deficiency
– Hyperhemolytic crisis (accelerated hemolysis with reticulocytosis): acute bacterial infections, exposure to oxidant

GENERAL PREVENTION
– Prevention of crises
  – Avoid hypoxia, dehydration, cold, infection, fever, acidosis, and anesthesia.
  – Prompt management of fever, infections, pain
  – Hydration
  – Avoid alcohol and smoking.
  – Avoid high-altitude areas.
– Minimizing trauma: Aseptic technique is imperative.

DIAGNOSIS
Diagnosis is often made by newborn screening programs.

HISTORY
– Often asymptomatic in early months of life due to presence of fetal hemoglobin
– In those >6 months of age, earliest symptoms are irritability and painful swelling of the hands
Manifestations in older children include anemia, severe or recurrent musculoskeletal or abdominal pain, aplastic crisis, acute chest syndrome, splenomegaly or splenic sequestration, and cholelithiasis.

Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.

Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions

**PHYSICAL EXAM**
Fever, pale skin and nail beds, mild jaundice

**DIFFERENTIAL DIAGNOSIS**
Anemia: other hemoglobinopathies

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Screening test: Sickledex test/Hb electrophoresis (diagnostic test of choice); SCA (FS pattern)
  - 80–100% Hb S, variable amounts of Hb F, and no Hb A1
  - Sickle cell trait (FS pattern): 30–45% Hb S, 50–70% Hb A1, minimal Hb F
- Hemoglobin ~5 to 10 g/dL; RBC indices: mean corpuscular volume (MCV) normal to increased; mean corpuscular hemoglobin concentration (MCHC) increased; reticulocytes 3–15%
- Leukocytosis; bands in absence of infection, platelets elevated; peripheral smear: sickled RBCs, nucleated RBCs, Howell-Jolly bodies
- Serum bilirubin mildly elevated (2 to 4 mg/dL); ferritin very elevated in multiply transfused patients; serum lactate dehydrogenase (LDH) elevated. Fecal/urinary urobilinogen high
- Haptoglobin absent or very low
- Urine analysis: hemoglobinuria, hematuria (sickle cell trait may have painless hematuria), increased albuminuria (Monitor for progressive kidney disease.)
- Imaging depends on clinical circumstances.
  - Bone scan to rule out osteomyelitis
  - Computed tomography/magnetic resonance imaging to rule out cardiovascular accident (CVA); high index of suspicion required for any acute neurologic symptoms other than mild headache
  - Chest x-ray: may show enlarged heart; diffuse alveolar infiltrates in acute chest syndrome
  - Transcranial Doppler: Start at age 2 years; repeat yearly. Transcranial Doppler ultrasound identifies children age 2 to 16 years at higher risk of stroke; may be normal in clinically silent strokes
  - ECG to detect pulmonary hypertension and echocardiogram every other year from age 15 years and older

**Test Interpretation**
Hyposplenism due to autosplenectomy is common; hypoxia/infarction in multiple organs
TREATMENT

GENERAL MEASURES

- Painful crises: hydration, analgesics; oxygen regardless of whether the patient is hypoxic
- Retinal evaluation starting at school age to detect proliferative sickle retinopathy
- Occupational therapy, cognitive and behavioral therapies, support groups
- All standard childhood vaccinations should be administered accordingly.
- Special immunizations
  - Influenza vaccine yearly
  - Conjugated pneumococcal vaccine (PCV13) at ages 2, 4, and 6 months; booster at 12 to 15 months
  - Patients <5 years of age with incomplete vaccination history should receive catch-up doses accordingly.
  - Adults age ≥19 years who have functional asplenia and have not received pneumococcal vaccination should receive 1 dose PCV13, followed by administration of PPSV23 at least 8 weeks later (1)[A].
- Meningococcal vaccine:
  - 6 weeks old: Hib-MenCY at ages 2, 4, 6, and 12 months
  - 9 months old: 2 doses of MCV4 separated by 3 months
  - ≥2 years of age: 2 doses of MCV4-D-CRM separated by 2 months; boosters recommended every 5 years

MEDICATION

First Line

- Prophylactic penicillins indicated in infants and children starting at 2 months: A dose of 125 mg BID is recommended for children <5 years. A dose of 250 mg BID is recommended for children >5 years. Amoxicillin 20 mg/kg/day is an alternative to penicillin; if high risk remains, continue until puberty (1)[A].
- Supplemental oxygen
- Painful crises (mild, outpatient)
  - Nonopioid analgesics (ibuprofen)
- Painful crises (severe, hospitalized)
  - Parenteral opioids (e.g., morphine on fixed schedule); patient-controlled analgesia (PCA) pump may be useful (1)[A]. Patients given strong opioids in the acute care setting should be safely monitored. Alternative to morphine as well as intranasal or transmucosal routes for rapid onset may be considered (2)[B].
- Hydroxyurea for prevention of painful acute chest syndrome, vaso-occlusive episodes, and very severe anemia. Increases fetal hemoglobin concentration. Adults: Start 15 mg/kg/day single daily dose; children: 20 mg/kg/day; titrate upward every 8 weeks (max dose of 35 mg/kg/day). Monitor blood counts (avoid severe neutropenia, thrombocytopenia) (1)[A].
- Acute chest syndrome: Patients may deteriorate quickly; monitor patients with vaso-occlusive crisis with incentive spirometry. Treat with aggressive management with oxygen, analgesics, antibiotics, and simple or exchange transfusion (1)[A].
- Empircic antibiotics to cover Mycoplasma pneumoniae and Chlamydia pneumoniae (cephalosporins or azithromycin) (1)[A]. If osteomyelitis, cover for Staphylococcus aureus and Salmonella (e.g., ciprofloxacin).
● Precautions: Avoid high-dose estrogen oral contraceptives; consider Depo-Provera. Granulocyte-colony stimulating factor use is contraindicated as it may lead to vaso-occlusive episodes and multiorgan failure.

**Second Line**
Folic acid: 0 to 6 months: 0.1 mg/day; 6 to 12 months: 0.25 mg/day; 1 to 2 years: 0.5 mg/day; >2 years of age: 1 mg/day

**ADDITIONAL THERAPIES**
Transfusions and additional therapies (1)[A]
- Transfusion for aplastic crises, severe complications (i.e., CVA), prophylactically before surgery, and treatment for acute chest syndrome; prophylactic transfusions for primary or secondary stroke prevention in children
- Preoperative transfusions have been shown to reduce the risk of perioperative complications.
- Consider chelation with deferasirox, an oral agent, if the patient is multiply transfused (after age 2 years). Red cell exchange transfusion minimizes risk of iron overload.

**SURGERY/OTHER PROCEDURES**
- Hematopoietic stem cell transplant (HSCT): curative, but with significant morbidity and mortality (3)[B]
- Oral therapy with l-glutamine has been shown to reduce oxidative stress and fewer episodes of sickle cell-related pain (4)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization: severe pain, suspected infection or sepsis, evidence of acute chest syndrome
- The preferred maintenance IV fluid is 1/2 NS because NS may theoretically increase the risk of sickling.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Treat infections early. Parents/patients: Any temperature of \( \geq 101^\circ\text{F} \) (38.3°C) requires immediate medical attention.
- Monitor for hepatitis C and hemosiderosis in patients who receive chronic transfusions.
- Periodic eye evaluations: starting age 10 years to detect proliferative sickle retinopathy; rescreen 1 to 2 year intervals.
- Biannual examination for hepatic, renal, and pulmonary dysfunction
- Neuroimaging screening for risk of stroke: transcranial Doppler beginning at age 2 years and continuing up to age 16 years
- Baseline pulmonary evaluation at each visit to assess for wheezing, shortness of breath, or cough (indicators of disease severity and pulmonary hypertension).
- Echocardiography for symptomatic patients; right heart catheterization for diagnosis
- Consider venous thromboembolism (VTE) prophylaxis.

**DIET**
- Folic acid supplementation; avoid alcohol (leads to dehydration); maintain hydration.
- Multivitamin without iron is recommended because there is high incidence of vitamin D deficiency and decreased bone marrow density in SCD patients.

PATIENT EDUCATION
- American Sickle Cell Anemia Association: http://www.ascaa.org

PROGNOSIS
- Anemia occurs in infancy; sickle cell crises at 1 to 2 years of age; some children die in their 1st year.
- In adulthood, fewer crises but more complications (mentioned below). Median age of death is 42 years for men and 48 years for women.

COMPLICATIONS
- Alloimmunization, bone infarct and osteomyelitis, aseptic necrosis of femoral head
- Cerebral strokes (peak age 6 to 7 years), impaired mental development, even without history of stroke
- Cholelithiasis/abnormal liver function
- Chronic leg ulcers, poor wound healing
- Impotence, priapism, hematuria/hyposplenuria, renal complications (proteinuria)
- Retinopathy, splenic infarction (by age 10 years)
- Acute chest syndrome (infection/infarction) leading to chronic pulmonary disease
- Infections (pneumonia, osteomyelitis, meningitis, pyelonephritis); sepsis (leading cause of morbidity and mortality)
- Hemosiderosis (secondary to multiple transfusions)
- Substance abuse related to chronic opioid use

Algorithm: Anemia

CODES

ICD10
- D57.212 Sickle-cell/Hb-C disease with splenic sequestration
- D57.211 Sickle-cell/Hb-C disease with acute chest syndrome
- D57.21 Sickle-cell/Hb-C disease with crisis

CLINICAL PEARLS
- >90,000 Americans have SCA (~1 in 375 African Americans).
- The preferred maintenance IV fluid is 1/2 NS because NS may theoretically increase the risk of sickling.
- Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.
- Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions
ANEURYSM OF THE ABDOMINAL AORTA
Katyayini Aribindi, MD ● Adrian DaSilva-DeAbreu, MD ● Raymundo A. Quintana, MD

BASICS

DESCRIPTION

- There are two types of aneurysms: true and false. A true aneurysm involves all three vessel wall layers. False aneurysms or pseudoaneurysms occur when the intimal and medial layers are disrupted, and the dilated segment is surrounded by the adventitia only, and possibly a perivascular clot. Ruptures are usually higher with false aneurysms due to poor support of the aneurysmal wall.
- Abdominal aortic aneurysm (AAA) is the most common true aneurysm. False aneurysms of the abdominal aorta are usually due to trauma or infection.
- The average diameter of the infrarenal aorta is 2.0 cm; an aortic diameter of ≥3.0 cm is considered aneurysmal.
- In men, AAA diameters are predictive of clinical events. In women, aneurysms are still defined as >3.0 cm, but the aortic scaling index (ASI; diameter [cm] / body surface area [m²]) is more predictive of clinical events.
- System(s) affected: cardiovascular; neurologic; heme/lymphatic/immunologic
- Synonym(s): aortic aneurysms; AAA

Geriatric Considerations
Incidence of AAA, risk of rupture, and operative morbidity and mortality all rise with age.

Pediatric Considerations
Rare in children; may be associated with umbilical artery catheters, connective tissue diseases, arteritides, or congenital abnormalities

EPIDEMIOLOGY

- Estimated prevalence of AAA in developed countries is 2–8%. Age-related increase is seen more with men than women.
- Ultrasound studies show that 4–8% of older men have an occult AAA.
- 90% of all AAA >4 cm are related to atherosclerotic disease, with the vast majority located infrarenally.
- Predominant sex: male > female

Incidence
- >10,000 deaths per year in United States
- 3.9–7.2% males >50 years
- 1.0–1.3% females >50 years

Prevalence
- Roughly 1 million U.S. individuals have an AAA, with the prevalence increasing in age for men and women.
- The prevalence of AAA-associated mortality has decreased by 50% since the 1990s, likely due
to the decline in cigarette smoking, increased screening for AAA detection, and early interventions.

- With the increasing life expectancy in developed countries, the prevalence of AAA is expected to increase, but the decreased prevalence of smoking will have the opposite effect.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- AAAs are caused by degradations of abnormal production of elastin and collagen, the structural components of the aortic wall.
- There are many causes of aortic aneurysms: inflammation, degenerative disorders, vasculitis, infections, and trauma. However, the vast majority of AAA are caused by inflammation with atherosclerosis as the inciting factor.
- B-cell and T-cell lymphocytes, macrophages, inflammatory cytokines, and matrix metalloproteinases degrade elastin and collagen, thus decreasing the aortic wall strength, leading to a decreased ability to accommodate the pulsatile flow.
- Histopathology shows elastin and collagen destruction, decreased vascular smooth muscle, ingrowth of new blood vessels, and subsequent inflammation.
- Although most aortic aneurysms are caused by inflammatory or degenerative destruction of elastin and collagen, infections, trauma, and connective tissues disorders can also degrade elastin and collagen, leading to similar presentations.

**Genetics**

- Familial aggregations exist: Aneurysms may develop at an earlier age.
- ~10% of AAA are familial, with a prevalence of 13% among affected families.
- Marfan syndrome
- Ehlers-Danlos syndrome
- Polycystic kidney disease
- Tuberous sclerosis

- Gene associations:
  - ANRIL: antisense RNA regulating cyclin-dependent kinase inhibitors
  - DAB2: cell growth and survival inhibitor
  - LRP1: low-density lipoprotein receptor–related protein 1, plasma receptor in vascular smooth muscle, and macrophage endocytosis
  - IL-6R and IL-1RN: part of the interleukin family contributing to IL-1 inhibition

**RISK FACTORS**

Older age, male sex, Caucasian race, family history, smoking, hypertension (HTN), hyperlipidemia, atherosclerosis, peripheral aneurysms, obesity

**GENERAL PREVENTION**

- Address cardiovascular disease risk factors.
- Follow screening guidelines: U.S. screening for detection of AAA in male patients, 65 to 75 years, who have ever smoked.

**COMMONLY ASSOCIATED CONDITIONS**

- HTN, myocardial infarction (MI), heart failure, carotid artery atherosclerosis, and/or lower extremity peripheral arterial disease
- Screening for thoracic aneurysm should also be considered.
- 20% of patients with AAA have concurrent thoracic aneurysm (1).
## DIAGNOSIS

- Asymptomatic AAA (majority)
  - USPSTF recommends a one-time screen for an AAA by abdominal ultrasonography for men aged 65 to 75 years with a smoking history (2)[A].
  - Selective screening for AAAs in nonsmoker men aged 65 to 75 years can be offered based on personal or family history and patient’s preferences (2)[A].
  - Current recommendations are against routine screening for women, regardless of smoking history.

## ALERT

- Symptomatic: The triad of shock, pulsatile mass, and abdominal pain always suggest rupture of AAA, and immediate surgical evaluation is recommended (1)[A].
  - Hemodynamically stable patients (shock is absent as the rupture is contained) may undergo a CT abdomen with IV contrast for evaluation of an AAA.
  - Unstable patients (rupture is uncontained) undergo a focused bedside ultrasound and surgical repair if AAA is present.

## Unusual presentations:
- Primary aortoenteric fistula: erosion/rupture of AAA into duodenum
- Aortocaval fistula: erosion/rupture of AAA into vena cava or left renal vein: 3–6%
- Inflammatory aneurysm: encasement by thick inflammatory rind; can cause chronic abdominal pain, weight loss, and elevated ESR. Surrounding viscera may be densely adherent.

## HISTORY

- Abdominal, back, or flank pain; AAA risk factors, hypotension if presenting in an emergency situation
- Found on routine screening if presenting in an outpatient setting

## PHYSICAL EXAM

- Pulsatile supraumbilical mass
  - In one study, sensitivity varied based on abdominal girth and size of aneurysm. However, the sensitivity was 100% of aneurysms >5.0 cm when the girth was <100 cm. The sensitivity and specificity varied from 23% to 68% and 75% to 91%, respectively (3).
- Encroachment by aneurysm
  - Vertebral body erosion, gastric outlet obstruction, ureteral obstruction
  - Lower extremity ischemia secondary to embolization of mural thrombus
- Rupture leads to tachycardia, hypotension, evidence of shock and anemia, and possible flank contusion (Grey Turner sign).

## DIFFERENTIAL DIAGNOSIS

- Other abdominal masses
- Other causes of abdominal or back pain (e.g., peptic ulcer disease, renal colic, diverticulitis, appendicitis, incarcerated hernia, bowel obstruction, GI hemorrhage, arthritis, metastatic disease, MI)

## DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- If rupturing AAA is considered: complete blood chemistry (chemistries, PT/INR, PTT, type and cross), ECG
- Ultrasound: simplest and least expensive diagnostic procedure with a high sensitivity (94–100%) and specificity (98–100%) (1)[A]
- Surveillance of asymptomatic aneurysm
  - 2.6 to 2.9 cm: Screen at 5-year intervals.
  - 3.0 to 3.9 cm: Screen at 3-year intervals.
  - 4.0 to 5.4 cm: Screen every 6 to 12 months.
- CT scans are preferred preoperative study (caution with IV contrast in renal failure) (1).
- MRI/MRA can visualize AAA but is often not possible in emergent situations.
- Aortography does not define outer dimensions of aneurysm.
- Abdominal x-rays can be diagnostic if calcifications exist; not a diagnostic tool of choice

Follow-Up Tests & Special Considerations
- Evaluation for coronary artery disease is appropriate prior to elective AAA repair, including stress test, echocardiography, and ECG if appropriate.
- If AAA was discovered at any location, then full assessment of entire aorta, including thoracic aorta and aortic valve, is recommended (1)[C].

Diagnostic Procedures/Other

ALERT
Use clinical judgment: Patients with known AAA having abdominal or back pain symptoms may be rupturing despite a negative CT scan.

TREATMENT

GENERAL MEASURES
- Treat atherosclerotic risk factors: HTN, dyslipidemia, diabetes mellitus, and smoking (2)[A].
- Smoking was associated with a 0.35 mm/year AAA growth, twice as fast as AAA growth in nonsmokers, and is the most important AAA outcome predictor (1).
- Emergent treatment in unstable or symptomatic patients requires immediate vascular surgery consultation, adequate IV access and resuscitation, type and cross for multiple units, and rapid bedside ultrasound (1).
- Less acute treatment of AAA/prevention of rupture is elective repair and risk factor modification.

MEDICATION
- β-Blockers, aspirin, and statins theoretically reduce the rate of growth of AAAs by decreasing shear wall stress, inflammation, and prevention of an intraluminal mural thrombus. However, there are conflicting RCT and meta-analysis trials. Because concomitant atherosclerosis is often a precipitating factor in AAAs, their use is recommended for reduced mortality in patients with coronary artery disease or its equivalents (4)[A].
- The use of ACE inhibitors has shown to be inconclusive with regard to growth of AAA; however, studies do indicate a decreased rate of AAA rupture (4)[A].
Doxycycline and roxithromycin, previously theorized to decreased wall inflammation, have not been shown to have any effect on AAA (5).

SURGERY/OTHER PROCEDURES
Current recommendations are the following:

- **Elective**
  - 5.5-cm diameter is threshold for repair in “average” patient (1)[A].
  - Younger, low-risk patients with long-life expectancy may prefer early repair.
  - Saccular aneurysms should be considered for elective repair (1)[C].
  - Women or AAA with high risk of rupture: Consider elective repair at 4.5 to 5.0 cm.
    - Consider delayed repair in high-risk patients.
    - 5% perioperative mortality for open elective repair (1)

- **High risk of rupture**
  - Expansion >0.5 cm/year
  - Smoking/COPD severe/steroids
  - Family history; multiple relatives
  - HTN if poorly controlled
  - Shape nonfusiform

- **High-risk patients for elective repair**
  - Risk factors for open repair include age >75 years, COPD, chronic kidney disease with Cr >1.75, and suprarenal clamp site.
  - The leading cause of early mortality after AAA repair is coronary artery disease, with open AAA repair being much higher risk than endovascular AAA repair (1)[A].

- The RCT IMPROVE trial showed a similar 30-day mortality for patients with ruptured AAA who underwent endovascular repair versus open repair (35.4% vs. 37.4%); 1-year follow-up all cause mortality between the two groups (41.1% vs. 45.1%) (5)[A]

- Although difficult to quantify, perioperative morbidity rates are lower for EVAR, suggesting that an EVAR is preferable in patients with a ruptured AAA with poor prognostic factors for an open repair, such as SBP <80, age >80 years, Cr >1.3 on admission, ischemic heart disease, female sex, and hemoglobin <9.0 on admission (2,5)[A].

- Contraindications for AAA endovascular repair are an aortic neck >32 mm and a ruptured AAA with aortic neck length <7 mm. In these patients, an open AAA repair is performed due to anatomical constrictions.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Risk of abdominal compartment syndrome after repair, 4–12%; usually associated with large fluid resuscitation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- May do a CT scan 5 years after an open repair for possible late aortic dilatation or pseudoaneurysm (2)[C]
- Follow-up imaging should be tailored to patient. Once renal function stabilizes postoperatively, a CT can be performed to evaluate the endograft (2)[C].
Aggressive risk factor modification always recommended postoperatively (2)[A]

Diet
Low-fat, low-salt, and low-caffeine diet; nutrition optimized prior to elective repair

Patient Education
Smoking cessation, aerobic exercise

Prognosis
- Naturally progressive disorder, expands at an average rate of 0.3 to 0.4 cm per year. A fast expansion is considered >0.6 cm per year and should be evaluated for operative management.
- Possibility of rupture increases with an aneurysm diameter of >5.5 cm or a fast rate of expansion (>0.5 cm over a 6-month period), continued cigarette use, female sex, recent surgery, uncontrolled HTN, and aneurysm couture.

Complications
- Emergent AAA repair and elective AAA repair have similar complications, with a higher incidence in emergent AAA repair.
- Complications include MI, respiratory failure, and acute kidney injury in the early period.
- Late complications such as aortic graft infection, aortoenteric fistula, and graft occlusion have similar rates between emergent and elective repair.
- Ischemic bowel and abdominal compartment syndrome are complications usually after a ruptured open AAA repair given the massive blood loss, increased operative time, and magnitude of fluid resuscitation.

CODES
ICD10
- I71.4 Abdominal aortic aneurysm, without rupture
- I71.3 Abdominal aortic aneurysm, ruptured

CLINICAL PEARLS
- Males with a smoking history aged 65 to 75 years should undergo a one-time screening abdominal ultrasound to evaluate for an AAA.
- Larger AAAs should be screened more often, with elective repair with AAA >5.5 cm or an expansion of >0.5 cm every 6 months.
- Patients with a ruptured AAA present in shock, with abdominal pain and a pulsatile mass. A bedside ultrasound should be done quickly to evaluate for an AAA, or an emergent CT scan can be performed if the patient is hemodynamically stable.
- AAA are treated either open or endovascularly as an elective or emergent procedure. 30-day and 1-year mortality between the two methods remain the same; however, there is increased mortality with an emergent AAA repair.
- Patients require aggressive risk factor modification, especially smoking cessation.
ANGIOEDEMA
Kathryn M. Brown, MD • Haley Stewart, DO • Katherine Montag Schafer, PharmD, BCACP

BASICS

DESCRIPTION
- Angioedema (AE) is acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of fluid into the affected tissues.
- AE develops in minutes to hours and resolves in hours to days but can be life-threatening if the upper airway is involved.
- Two major classifications of AE exist:
  - Histamine- or immune-mediated AE (HIAE) with urticarial
  - Bradykinin-mediated AE without urticaria; both with unique subtypes
- Synonym(s): angioneurotic edema; Quincke edema

EPIDEMIOLOGY
- Predominant age
  - HIAE or idiopathic AE (IAE): any age
  - Hereditary AE (HAE): age of onset infancy to 2nd decade of life
  - Acquired AE (AAE): often patients >40 years
- Predominant gender: male = female (except HAE with normal complement: women > men)

Prevalence
- AE occurs in 15% of the population over a lifetime.
- AE: 0.1–2.2% of patients receiving angiotensin-converting enzyme (ACE) inhibitors: African Americans have a 4 to 5 times greater risk of ACE inhibitor–induced AE than Caucasians.
- HAE: 1:10,000 to 50,000 population in the United States

ETIOLOGY AND PATHOPHYSIOLOGY
- HIAE with urticarial (1):
  - Allergy to food (shellfish, nuts, eggs, milk, wheat soy), latex, venom, or medication (aspirin, NSAIDs, antibiotics, narcotics, and OCPs)
  - Acute and chronic spontaneous urticaria
  - Other urticarial/AE syndromes: cold urticaria, urticarial vasculitis, exercise-induced urticaria or anaphylaxis, episodic eosinophilia with AE, vibration-induced urticaria
  - IAE
- Bradykinin-mediated AE without urticarial (1):
  - Attacks are triggered by prolonged mechanical pressure, cold, heat, trauma, emotional stress, menses, illness, and inflammation.
  - HAE due to C1 INH deficiency
    - Type I: the most common form, caused by decreased production of C1 esterase inhibitor (C1 INH)
    - Type II: functionally impaired C1 INH
  - HAE with normal C1 INH levels
Formerly type III HAE
- Involves mutations in coagulation factor XII gene, often estrogen dependent, associated with estrogen administration
- AAE with C1 INH deficiency
  - Rare condition
  - Associated with lymphoproliferative disorders, autoimmune diseases (e.g., lupus)
  - Type I: lack of anti-C1 INH autoantibody
  - Type II: presence of anti-C1 INH autoantibody
- AE due to medications
  - ACE inhibitors
  - Dipeptidyl peptidase-4 inhibitors
  - Direct renin inhibitor
- IAE

Genetics
- HAE types I and II are autosomal dominant, whereas HAE with normal C1 INH is dominant X-linked.
- HAE occurs in 25% of patients as a result of spontaneous genetic mutations.

RISK FACTORS
- Consuming medications and foods that can cause allergic reactions
- Preexisting diagnosis of HAE or AAE
- Positive family history

GENERAL PREVENTION
- Avoid known triggers.
- Do not use ACE inhibitors in type I or II HAE.

COMMONLY ASSOCIATED CONDITIONS
- Quincke disease (AE of the uvula)
- Urticaria

DIAGNOSIS

HISTORY
- Acute, typically asymmetric, swelling with onset in minutes to hours (2)
- In comparison with urticaria, AE typically is nonpruritic, but it can cause a painful, burning sensation (2).
- Recent exposure to food allergens or medications (2)
- Identify potential triggers such as environmental exposure or trauma (2).
- Family history of AE (2)
- Recent infection, history of autoimmune disease, or malignancy (3)

PHYSICAL EXAM
- Vitals: Symptoms of hypotension, tachycardia, and tachypnea indicate systemic involvement and increased severity (3).
- Tense, nonpitting skin swelling that is skin colored or slightly erythematous (2)
- Commonly affects the mucus membranes of the face including periorbital, lips, tongue, or larynx but can involve any part of the body (2).
- Evaluate for involvement of oropharynx or symptoms such as stridor (3).
- GI tract involvement is more common in HAE and AAE and may manifest as intermittent, unexplained abdominal pain (2).
- May be accompanied by hives and itching (1).

**ALERT**
- Select history and exam findings increase the likelihood for early intubation and tracheostomy, including involvement of the anterior tongue, base of the tongue or larynx, stridor within 4 hours of onset of symptoms, and drooling (1)[C].
- Patients with HAE or bradykinin-mediated AE are at higher risk for intubation, tracheostomy, and death, although these complications can occur with any subtype (3)[C].

**DIFFERENTIAL DIAGNOSIS**
Urticaria; anaphylaxis; contact dermatitis; food/drug allergy; erysipelas; connective tissue disease: systemic lupus erythematosus, dermatomyositis; lymphedema; insect bite reaction; diffuse subcutaneous infiltrative process (4)[C]

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Initial diagnosis should be based on history and clinical assessment alone (3)[C].
- Laboratory testing includes CBC, ESR, complement testing (C4, C1 INH, C1 INH function), allergy testing, and screening for paraproteinemia (1,2)[C].
- For emergent management, C4 and tryptase levels may assist in diagnosis of HAE and AE associated with anaphylaxis (3)[C].
- Complement testing assists in distinguishing between various types of HAE and AAE (1)[C]:
  - Low serum C4 is a sensitive but nonspecific screening test for hereditary and acquired C1 INH deficiency.
  - If C4 is normal, determine C1 INH level and function and recheck C4 during an acute attack.
  - If C4 level and C1 INH level and function are still normal, consider other causes (i.e., medications or HAE type III) of AE.
  - If C4 level, C1 INH level, and C1 INH function are low, these indicate HAE type I.
  - HAE type II is characterized by low C4 and low C1 INH function, but C1 INH level can be normal or elevated.
- For recurrent AE with urticaria, complement levels should be obtained in addition to allergy testing for potential triggers (1)[C].
- Abdominal radiographs and CT scan can demonstrate GI AE or ileus (1)[C].
- C1 INH deficiency may occur in association with internal malignancy, so AE rarely can be a paraneoplastic disease. Imaging (CT scan, radiography, etc.) would be done as part of a neoplastic workup for patients with AAE (1)[C].

**Follow-Up Tests & Special Considerations**
If C4 and C1q antigen are low (as in AAE), neoplastic and autoimmune workup is warranted. CBC, a peripheral smear, protein electrophoresis, immunophenotyping of lymphocytes, and imaging studies are often undertaken to rule out hematologic malignancies or cancer (2)[C].
TREATMENT

GENERAL MEASURES

- Intubation if airway is threatened (3)[C]
- Eliminate suspected trigger (2)[C].
- Volume replacement is essential for patients who are unstable or refractory to initial therapy (3)[C].

MEDICATION

First Line

- If AE presenting with signs of anaphylaxis (hypotension, respiratory compromise): epinephrine 1:1,000; 0.1 mg/kg (maximum 0.3 mg for children, 0.5 mg for adults) intramuscularly q5–15min (3,5)[C]
- If cause of AE is unknown:
  - $H_1$ antagonist (IV diphenhydramine, adult: 25 to 50 mg, children: 1 mg/kg, maximum 50 mg). In older adults, side effects can include delirium, urinary retention, constipation, and increased ocular pressure (3,5)[C].
  - $H_2$ antagonists (IV ranitidine, adult: 50 mg, children: 1 mg/kg, maximum 50 mg) (3,5)[C]
  - Corticosteroids (IV hydrocortisone, adult: 200 mg, children: maximum 100 mg; or IV methylprednisolone, adult: 50 to 100 mg, children: 1 mg/kg, maximum 50 mg) (3,5)[C]
- HIAE acute treatment: $H_1$ antagonist, $H_2$ antagonist, corticosteroids, and epinephrine, if airway involvement (3,5)[C]
  - If time critical, IV therapy preferred
  - If time is not critical, can consider 2nd-generation (nonsedating) $H_1$ antagonist
- HAE acute treatment:
  - $H_1$ antagonists, corticosteroids, and epinephrine are ineffective and not recommended (6)[C].
  - GI involvement: analgesics and antiemetics for pain and nausea (3)[C]
  - Ruconest (recombinant human C1 INH): Trained adult and adolescent (13 to 17 years of age) patients may self-administer via slow IV injection (over 5 minutes). Dosing: 50 U/kg (maximum 4,200 U) if <84 kg and 4,200 IU if ≥84 kg. Maximum of 2 doses in 24 hours. Serious adverse reaction: anaphylaxis (1)[C]
  - Berinert (human plasma-derived [pd] C1 INH [pdC1 INH]): Trained adult and adolescent patients may self-administer via peripheral vein IV infusion (4 mL/min). Dosing: 20 U/kg. Do not shake (will denature the protein). Serious adverse reaction: anaphylaxis (1)[C]
  - Ecallantide (Kalbitor): labeled for use in those ≥12 years. Dosing: 30 mg subcutaneously (SC) with three separate 10 mg/mL injections in the abdomen, thigh, or upper arm, and a second 30-mg dose may be repeated within 24 hours if needed. Injection-site rotation is not necessary but must be 2 inches away from attack site. Serious adverse reaction: anaphylaxis; unlike previous agents, required administration in health care setting (1)[C]
  - Icatibant (Firazyr): Adult patients may self-administer via slow SC injection (over 30 seconds). Dosing: 30 mg in the abdomen, thigh, or upper arm. Subsequent doses of 30 mg may be repeated in 6-hour intervals (max 90 mg/24 hours) (1)[C].
- AAE acute treatment:
– H₁ antagonists, corticosteroids, and epinephrine are ineffective and not recommended (6)[C].
– Off-label uses: C1 INH replacement, ecallantide, icatibant (1,6)[C]
– Associated improvement, possible remission, through treatment of underlying disease (6)[C]

• IAE, recurrent, acute treatment:
  – H₁ antagonists, corticosteroids, and epinephrine may be effective (1,2)[C].
  – Anecdotal, off-label uses: C1 INH replacement, ecallantide, icatibant (1)[C]

• HAE prophylaxis:
  – All patients are eligible for short-term prophylaxis during periods where known exposure to trigger is expected (e.g., dental work, invasive medical or surgical procedures) (6)[C].
    – Off-label use: Cinryze (IV pdC1 INH concentrate), androgens (danazol)
  – During these exposures, should ensure access to acute treatment modalities (6)[C]
  – In patients not managed successfully with acute treatment, can consider use of long-term prophylactic agent (6)[C]
  – FDA-approved therapies: Cinryze (IV pdC1 INH concentrate), Haegarda (SC pdC1 INH concentrate), lanadelumab (Takhzyro), androgens (danazol)

Second Line
HAE acute treatment: FFP can be considered if first-line treatments unavailable; however, can potentially worsen attack, so caution is required (6)[C]

ISSUES FOR REFERRAL
Patients presenting with first episode of AE with a positive family history or recurrent AE will benefit from management from allergy/immunology specialist for diagnosis, treatment selection, education, and formation of emergency and procedural action plans (3)[C].

SURGERY/OTHER PROCEDURES
Tracheostomy if progressive laryngeal edema prevents endotracheal intubation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Need for admission is based on severity of airway involvement. Ishoo criteria can be used for risk stratification. All patients with respiratory distress or in need of airway support will benefit from treatment in an intensive care unit (3)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
• Diagnostic workup if symptoms are severe, persistent, or recurrent
• For those with recurrent AE, specialty management is recommended.

DIET
Avoid identified food allergens.

PATIENT EDUCATION
Educate on avoidance of known triggers, types of treatment, when to seek emergency care, and
wearing medical alert bracelet.

**PROGNOSIS**

- AE symptoms often resolve in hours to 2 to 4 days. If airway is compromised, AE can be life-threatening.
- Patients with HAE have an average of 20 attacks per year; each may last 3 to 5 days. Prophylaxis can decrease the frequency of events and number of missed days of school or work.

**COMPLICATIONS**

Anaphylaxis

**REFERENCES**

**SEE ALSO**

Anaphylaxis; Urticaria

**CODES**

**ICD10**

- T78.3XXA Angioneurotic edema, initial encounter
- D84.1 Defects in the complement system

**CLINICAL PEARLS**

- AE is an acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of fluid into the affected tissues.
- Onset is in minutes to hours and often resolves in hours to days, but it can be life-threatening if the upper airway is involved.
- There are two major classifications of AE: HIAE and bradykinin-mediated AE (subtypes
include HAE and AAE). IAE can be of either type.
- HIAE is more likely to be associated with urticaria and responsive to H₁ antagonists, corticosteroids, and epinephrine.
- Any recurrent AE requires specialist management.
- Patients with a history of HIAE should be prescribed an epinephrine autoinjector.
ANKLE FRACTURES
Jeffrey P. Feden, MD, FACEP

BASICS
- Bones: tibia, fibula, talus
- Mortise: tibial plafond, medial and lateral malleolus
- Ligaments: syndesmotic, lateral collateral, and medial collateral (deltoid) ligament

DESCRIPTION
- Two common classification systems help describe fractures (but do not always predict fracture stability).
  - Danis-Weber system: based on level of the fibular fracture in relationship to the ankle joint
    o Type A (30%): below ankle joint; usually stable
    o Type B (63%): at the level of the ankle joint; may be stable or unstable
    o Type C (7%): above ankle joint; usually unstable
  - Lauge-Hansen (LH): based on foot position and direction of applied force relative to the tibia
    o Supination-adduction (SA)
    o Supination-external rotation (SER): most common (40–75% of fractures)
    o Pronation-abduction (PA)
    o Pronation-external rotation (PER)
- Stability-based classification
  - Stable
    o Isolated lateral malleolar fractures (Weber A/B) without talar shift and with negative stress test
    o Isolated nondisplaced medial malleolar fractures
  - Unstable
    o Bi- or trimalleolar fractures
    o High fibular fractures (Weber C) or lateral malleolar fracture with medial injury and positive stress test
    o Lateral malleolar fracture with talar shift/tilt (bimalleolar equivalent)
    o Displaced medial malleolar fractures
- Pilon fracture: tibial plafond fracture due to axial loading (unstable)
- Maisonneuve: fracture of proximal 1/3 of fibula associated with ankle fracture (unstable); high risk of peroneal nerve injury

Pediatric Considerations
- Ankle fractures are more common than sprains in children compared to adults because ligaments are stronger than physis.
- Talar dome: osteochondral fracture of talar dome; suspect in child with nonhealing ankle “sprain” or recurrent effusions.
- Tillaux: isolated Salter-Harris III of distal tibia with growth plate involvement
- Triplane fracture: Salter-Harris IV with fracture lines oriented in multiple planes: 2-, 3-, and 4-part variants
EPIDEMIOLOGY
- Ankle fractures are responsible for 9% of all adult and 5% of all pediatric fractures.
- Peak incidence: females 45 to 64 years; males 8 to 15 years (average is 46 years)

Incidence
107 to 184 per 100,000 people per year

ETIOLOGY AND PATHOPHYSIOLOGY
- Most common: falls (38%), inversion injury (32%), sports related (10%)
- Plantar flexion (joint less stable in this position)
- Axial loading: tibial plafond or pilon fracture

RISK FACTORS
- Age, fall, fracture history, polypharmacy, intoxication
- Obesity, sedentary lifestyle
- Sports, physical activity
- History of smoking or diabetes
- Alcohol or slippery surfaces

GENERAL PREVENTION
- Nonslip, flat, protective shoes
- Fall precautions in elderly

COMMONLY ASSOCIATED CONDITIONS
- Most ankle fractures are isolated injuries, but 5% have associated fractures, usually in ipsilateral lower limb.
- Ligamentous or cartilage injury (sprains)
- Ankle or subtalar dislocation
- Other axial loading or shearing injuries (i.e., vertebral compression or contralateral pelvic fractures)

DIAGNOSIS

HISTORY
- Location of pain, timing, and mechanism of injury (key historical element is exact mechanism)
- Weight-bearing status after injury
- History of ankle injury or surgery
- Tetanus status
- Assess for safety and fall risk (especially in elderly).

PHYSICAL EXAM
- Examine skin integrity (open vs. closed fracture).
- Assess point of maximal tenderness.
- Assess neurovascular status and ability to bear weight.
- Consider associated injuries.
- Assess ankle stability: anterior drawer test for the anterior talofibular ligament (ATFL), talar tilt test for lateral and medial ligaments, squeeze test and external rotation stress test for the
tibiofibular syndesmosis.

DIFFERENTIAL DIAGNOSIS
- Ankle sprain
- Other fractures: talus, 5th metatarsal, calcaneus

DIAGNOSTIC TESTS & INTERPRETATION
- Plain radiographs: first line for suspected fractures based on pretest probability (Ottawa Rules)
- Ottawa Ankle Rules (OAR): Overall sensitivity of 98% in adults increases to 99.6% if applied within the first 48 hours after trauma (1)[A].
- OAR obtain films in patients aged 18 to 55 years if:
  - Tenderness at the posterior edge of distal 6 cm of tibia or tip of the medial malleolus, or
  - Tenderness at the posterior edge or distal 6 cm of fibula or tip of the lateral malleolus, or
  - Inability to bear weight both immediately and in the ED for four steps, or
  - Tenderness at navicular or 5th metatarsal (Ottawa Foot Rules)
- If initial x-ray is normal, but severe symptoms persist past 48 to 72 hours, obtain repeat x-rays.
- In children >1 year old, OAR sensitivity is 98.5%.
- OAR not valid for intoxicated patients, those with multiple injuries, or sensory deficits (neuropathy)
- Three standard views
  - Anteroposterior (AP)
  - Lateral: Talar dome/distal tibia incongruity indicates instability.
  - Mortise (15- to 25-degree internal rotation view): symmetry of mortise; space between the medial malleolus and talus should be ≤4 mm.
  - Additional stress view may demonstrate instability: increased medial clear space with manual external rotation

Pediatric Considerations
- Consider tenderness over distal fibula with normal films as Salter-Harris I.
- Stress views unnecessary in children and may cause physeal damage.
- Salter-Harris V often missed, diagnosed when leg length discrepancy or angular deformity after Salter-Harris I; rare, 1% of fractures

Follow-Up Tests & Special Considerations
- CT recommended for operative planning in trimalleolar, Tillaux, triplane, pilon fractures, or fractures with intra-articular involvement
- MRI not routinely indicated; does not increase sensitivity for detecting complex ankle fractures
  - MRI useful for chronic instability, osteochondral lesions, occult fractures, and unexpected stiffness in children

Diagnostic Procedures/Other
- Ultrasound for soft tissue injury associated with displaced fractures
- Bone scan or MRI for stress fracture

TREATMENT

GENERAL MEASURES
Immobilize in temporary cast/splint and protect with crutches/non–weight-bearing.
  – 1 to 2 weeks to allow decreased swelling, if not open or irreducible fracture (2)[C]

Ice and elevate the extremity; pain due to swelling best controlled with elevation
  – Compression stockings offer no benefit for swelling (3)[A].

Closed ankle fractures—must determine stability
  – Stable = nonoperative
  – Unstable = surgery
  – Lateral shift of talus ≥2 mm or displacement of either malleolus by 2 to 3 mm = surgery (2)

  [C]
  – In adults with displaced fractures: insufficient evidence if surgery or nonoperative
    management produces superior long-term outcomes (4)[A]

Stable syndesmosis injury = nonoperative

Fracture dislocations: urgent reduction
  – Do not wait for imaging if neurovascular compromise or obvious deformity.
  – Flex hip and knee 90 degrees for easier reduction.
  – Postreduction: neurovascular exam and x-rays

**MEDICATION**

**First Line**

- NSAIDs and/or acetaminophen for pain
- Initial IM pain injection (i.e., ketorolac, ≥50-kg adult: 60 mg or 30 mg q6h, max 120 mg daily; children 2 to 16 years old, <50 kg or age of ≥65 years: 1 mg/kg, 30 mg, or 15 mg q6h, max 60 mg daily)
- For suspected open fractures: tetanus booster, broad-spectrum cephalosporin and aminoglycoside within 3 hours postinjury (2)[C]
- Intra-articular or hematoma block

**Second Line**

Opioid analgesics as adjunctive therapy

**ISSUES FOR REFERRAL**

- Consultation for neurovascular compromise, tenting of skin or open fracture, displaced or unstable fracture, compartment syndrome
- All other fractures: Follow up within 1 week and remain non–weight-bearing. Consult orthopedics if not comfortable with routine fracture management.

**ADDITIONAL THERAPIES**

- Nonoperative = cast immobilization
  – No difference in type of immobilization (Air-Stirrup, cast, orthosis) (3)[A]
  – Initially non–weight-bearing with crutches and then advance to 50% with crutches; full weight-bearing after 6 weeks postinjury
  – If removable cast, gentle range of motion exercises at 4 weeks
- Open ankle fractures (2%)
  – Remove gross debris/contamination in ED.
  – Duration of optimal antibiotic therapy controversial
  – Surgical emergency; best if repaired within 24 hours

**SURGERY/OTHER PROCEDURES**
Surgical options
- Open reduction and internal fixation (ORIF); preferred in athletes and unstable fractures
- External fixation may be preferred in extreme tissue injury or comminuted fractures; may have more malunion compared to ORIF but no difference in wound complications

Timing of surgery
- Immediately if neurovascular compromise, open fracture, unsuccessful reduction, tissue necrosis (2)[C]
- Otherwise delay >5 days postinjury because inflammation can affect wound healing (2)[C].

Length of recovery is usually 6 to 8 weeks.

Pediatric Considerations
- Salter-Harris I and II = nonoperative
  - Distal tibia: long leg cast for 4 to 6 weeks and then short leg cast for 2 to 3 weeks (5)[C]
  - Distal fibula: posterior splint or ankle brace 3 to 4 weeks, weight-bearing; if displaced, then short leg cast 4 to 6 weeks, non–weight-bearing (5)[C]
  - Limit reduction attempts because of potential injury to growth plate (5,6)[C].
  - Reduction not recommended if presenting ≥1 week postinjury (5)[C]
  - Intra-articular displacement of ≥2 mm in child with >2 years growth remaining = ORIF (6)[C]
- Salter-Harris III and IV:
  - Distal tibia: if >2 mm displacement = ORIF (6)[C]
  - Distal fibula: rare, usually stable after tibial reduction (6)[C]
  - Tillaux and triplane: ORIF if displaced ≥2 mm (5,6)[C]

Geriatric Considerations
- Higher surgical risk due to age/comorbidities
- Osteoporosis increases risk of implant/fixation failure (4)[A].
- Risks from surgery/anesthesia: wound healing problems, pulmonary embolism, mortality, amputation, reoperation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit if:
  - Emergency surgery required
  - Patient nonadherent, lacks social support, unable to maintain non–weight-bearing status, or has significant associated injuries
  - Concerning mechanism of injury (i.e., syncope, myocardial infarction, head injury)
- Nursing: non–weight-bearing; maintain splint/cast; apply ice; keep leg elevated; pain control; assist ADLs.
- Discharge criteria:
  - Ambulates with walker or crutches
  - Medical workup (if needed) completed
  - Orthopedic follow-up arranged

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Orthopedic follow-up: serial x-rays
  - In children, sclerotic lines on x-ray (Parker-Harris growth arrest lines) indicate growth disturbance (5)[C].
- Immobilize for 4 to 6 weeks and then progressive activity, weight-bearing, with removable splint or boot (3)[A].
- Physical therapy referral: no difference in outcomes between stretching, manual therapy, exercise program (3)[A]

DIET
NPO if surgery is being considered

PATIENT EDUCATION
- Ice and elevate for 2 to 3 weeks; use crutches/cane as instructed; splint/cast care (avoid getting wet, etc.)
- Notify physician if swelling increases, paresthesias, pain, or change in color of extremity.

PROGNOSIS
- Good results can be achieved without surgery if fracture is stable.
  - Most return to activity within 3 to 4 months.
- Most athletes return to preinjury activity levels.
- Increasing age, not injury severity, is associated with worsening mobility after fracture.

COMPLICATIONS
- Displaced fracture or instability
- Delayed union, malunion, or nonunion (0.9–1.9%)
- Postsurgical wound problems: loss of fixation, further surgery, amputation
- Deep venous thrombosis
- Complex regional pain syndrome, extensor retinaculum syndrome in children (5)[C]
- Infection (osteomyelitis)
- Posttraumatic arthritis, degenerative joint disease, growth arrest in children

REFERENCES
ICD10
- S82.899A Oth fracture of unsp lower leg, init for clos fx
- S82.899B Oth fracture of unsp lower leg, init for opn fx type I/2
- S82.56XA Nondisp fx of medial malleolus of unsp tibia, init

CLINICAL PEARLS
- OAR are nearly 100% sensitive in determining the need for x-rays.
- Assess neurovascular status, ability to bear weight, and associated injuries.
- Assess joint above/below to avoid overlooking extent of injury (i.e., Maisonneuve).
- Normal x-rays with point tenderness suggest Salter-Harris type I fractures in children.
- Assessment of fracture stability (using classification systems) often dictates conservative versus operative management.
ANKYLOSING SPONDYLITIS
Ryan Kavilaveettil, DO  Gwenesta B. Melton, MD

BASICS

DESCRIPTION
- Ankylosing spondylitis (AS) is an axial inflammatory spondyloarthropathy (axSpA) characterized by evidence of sacroiliitis (sclerosis, erosions, and changes in joint width) on plain radiography.
- System(s) affected: musculoskeletal; eyes; cardiac; neurologic; pulmonary
- Synonym(s): Marie–Strümpell disease; “bamboo spine”

EPIDEMIOLOGY
- Onset usually in early 20s; rarely occurs after age 40 years
- Male > female (approximately 2 to 3:1)

Incidence
Age- and gender-adjusted rate of 6.3 to 7.3/100,000 person-years

Prevalence
~0.55% for AS and ~1.4% for all axSpA in the United States (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Autoinflammation at sites of bacterial exposure (e.g., intestines) or mechanical stress in genetically susceptible individuals (2)
- Inflammation at the insertion of tendons, ligaments, and fasciae to bone (enthesopathy) causes erosion, remodeling, and new bone formation.
- Inflammation-independent pathways of bony changes have also been hypothesized (2).

Genetics
- 85–95% of patients with AS are HLA-B27–positive.
- Other genetic associations include endoplasmic reticulum aminopeptidase 1 (ERAP1), interleukin-23 receptor (IL23R), and gene deserts on chromosome 2p15 and 21q22 (2).

RISK FACTORS
- HLA-B27
  - 1–8% of HLA-B27–positive adults have AS.
- Positive family history
  - HLA-B27–positive child of a parent with AS has a 10–30% risk of developing the disease.

COMMONLY ASSOCIATED CONDITIONS
- Peripheral arthritis (30%)
- Enthesopathy (29%): Achilles tendonitis, plantar fasciitis
- Uveitis (25–35%)
- Psoriasis (10%)
- Dactylitis “sausage digit” (6%)
- Inflammatory bowel disease (IBD) (4%) (3)[A]
Peripheral spondyloarthritis (SpA): psoriatic arthritis, reactive arthritis, IBD-related arthritis, juvenile idiopathic arthritis
Aortitis and cardiac conduction defects

DIAGNOSIS

HISTORY

- Inflammatory back pain
  - Insidious onset
  - Duration >3 months
  - Morning stiffness in spine lasting >1 hour
  - Nighttime awakenings secondary to back pain
  - Pain and stiffness increase at rest and improve with activity.
- Alternating buttock/hip pain is common.
- Constitutional symptoms (fatigue, weight loss, low-grade fever) are common.
- Inspirational chest pain due to enthesitis at costochondral junction and diminished chest wall expansion
- Other symptoms associated with enthesopathy (Achilles pain, plantar fascia pain), dactylitis (oligoarthritis), iritis (painful red eye, photophobia, vision changes)

PHYSICAL EXAM

- Sacroiliac (SI) joint tenderness, loss of lumbar lordosis, and cervical spine rotation
- Diminished range of motion in the lumbar spine in all three planes of motion
- Modified Wright-Schober test for lumbar spine flexion:
  - Mark patient’s back over the L5 spinous process (or at dimples of Venus) and measure 10 cm above and 5 cm below this point. Normal is at least 5 cm of expansion between these two marks on maximal forward flexion.
- Thoracocervical kyphosis (usually after at least 10 years of symptoms)
- Occiput–wall distance increased (distance between occiput and wall when standing with back flat against a vertical surface; zero is normal)
- Respiratory excursion of chest wall
  - Normal is >5 cm of maximal respiratory excursion of chest wall measured at 4th intercostal space; <2.5 cm is consistent with AS.
- Tenderness of insertional sites—Achilles, plantar fascia
- Peripheral oligoarthritis/dactylitis seen mostly with peripheral SpA
- Cauda equina syndrome rarely occurs in late disease.
- Extra-articular manifestations: uveitis, psoriasis, IBD
- Aortic regurgitation murmur (1%)

DIFFERENTIAL DIAGNOSIS

- Nonradiographic axSpA (features of AS with evidence of sacroiliitis on MRI but not on plain radiographs—can progress to AS); other SpA
- Osteoarthritis of the axial spine
- Diffuse idiopathic skeletal hyperostosis (DISH)
- Osteitis condensans illii: benign sclerotic changes in the iliac portion of the SI joint after pregnancy
Infectious arthritis or discitis, unilateral sacroiliitis: tuberculosis, brucellosis, bacterial infection (particularly in IV drug users)

Vertebral compression fracture

Familial Mediterranean fever

DIAGNOSTIC TESTS & INTERPRETATION

Up to 10% of Caucasian population and 4% of African American population are HLA-B27-positive. Genetic testing is not necessary as part of initial evaluation, particularly with a consistent history and exam.

Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) may be mildly elevated or normal; if high, correlates with disease activity and prognosis

Absence of rheumatoid factor

Mild normochromic anemia (15%)

Synovial fluid: mild leukocytosis

SI joints: Oblique projection is preferred.

– X-ray changes may not be apparent for up to 10 years after disease onset. MRI is more sensitive; increased signal from the bone and bone marrow suggests osteitis and edema.

– Sequential radiographic changes over time: widening of SI joint, erosions, sclerosis on both sides of joint not extending >1 cm from articular surface, and (lastly) ankyloses

Spine: lateral view preferred

– Early plain radiograph changes: “shiny corners” due to osteitis and sclerosis at site of annulus fibrosus attachments to the corners of vertebral bodies with “squaring” due to erosion and remodeling of vertebral body; contrast-enhanced MRI is more sensitive for detecting early changes.

– Late changes: ossification of annulus fibrosis resulting in bony bridging between vertebral bodies (syndesmophytes) giving classic “bamboo spine” appearance; ankylosis of apophyseal joints, ossification of spinal ligaments, and/or spondylodiscitis also occurs.

Peripheral joints

– Asymmetric pericapsular ossification, sclerosis, loss of joint space, and erosions may occur.

Diagnostic Procedures/Other

Screening for cardiac conduction defects with ECG and for valvular heart disease with echocardiograms not recommended but may consider if symptomatic

Test Interpretation

Erosive changes and new bone formation at bony attachment of the tendons and ligaments result in ossification of periarticular soft tissues.

Synovial hypertrophy and pannus formation, mononuclear cell infiltrate into subsynovial and subchondral bone marrow inflammation in the SI joint with erosions, followed by granulation tissue formation, and finally obliteration of joint space by fusion of joint and sclerosis of pararticular bone.

TREATMENT

GENERAL MEASURES

Symptom control, maintaining spinal flexibility and normal posture, reducing functional limitations, maintain work ability, and decreased disease complications are primary treatment
goals.
- Aggressive physical therapy is the most important nonpharmacologic management.
- Posture training and spinal range-of-motion exercises are essential.
- Firm bed; sleep in supine position without a pillow.
- Breathing exercises 2 to 3 times per day
- Smoking cessation

MEDICATION

First Line
- Nonsteroidal anti-inflammatory drugs (NSAIDs) are first-line pharmacologic agent for pain and stiffness in AS (4)[A].
- NSAIDs provide rapid and dramatic symptomatic relief, which may aid in diagnosis. No single NSAID preferred. Higher doses tend to be more efficacious.
- NSAIDs may be effective in slowing radiographic disease progression, and this may be best achieved by continuous rather than on demand use (4)[A].
- Precautions
  - Consider cardiovascular disease, gastrointestinal (GI), and renal risks of NSAIDs. Use with caution in patients with a bleeding diathesis or on anticoagulants.
  - Consider GI prophylaxis (proton pump inhibitors or misoprostol) while on NSAIDs in patients with hx of peptic ulcer disease, gastritis, or age >60 years.
- Injection of intra-articular corticosteroids into SI joints and prostheses can provide transient relief, but systemic corticosteroids are not recommended (5)[C].

Pregnancy Considerations
Infants exposed to NSAIDs in 1st trimester may have a higher incidence of cardiac malformations.

Second Line
- Biologic agents: tumor necrosis factor (TNF)-α antagonists
  - Recommended for active disease after lack of response to at least two different NSAIDs over 1 month (5)[C]
  - FDA-approved agents for AS include etanercept (recombinant TNF receptor fusion protein), infliximab (chimeric monoclonal IgG1 antibody to TNF-α), adalimumab (fully humanized IgG1 monoclonal antibody to TNF-α), and golimumab (human IgG1 kappa monoclonal antibody to TNF-α).
  - Approved agents improve pain, function, and symptoms of AS as compared to placebo (6)[A].
  - No definitive evidence for TNF-α blockers with regard to disease remission, prevention of radiologic progression, or prevention of extra-articular manifestations
  - Monoclonal TNF-α blockers are preferred when IBD is involved (5)[C].
  - Further investigation as to the effectiveness of TNF blocker therapy with NSAIDs is needed.
- Precautions with TNF-α blockers
  - Anti-TNFs increase the risk of serious bacterial, mycobacterial, fungal, opportunistic, and viral infections. Screen for tuberculosis and hepatitis B.
  - Monitor for reactivation of tuberculosis and invasive fungal infections, such as histoplasmosis, in all patients, especially those who travel to (or residents in) endemic areas.
Lymphomas, nonmelanoma skin cancers, and other malignancies have been reported in patients receiving anti-TNFs. Immunizations (especially live vaccines) should be updated before initiating anti-TNFs; live vaccines are contraindicated once patients receive anti-TNFs. Secukinumab (IL-17A monoclonal antibody) has been shown to be a reasonable alternative to TNF inhibitor, however it lacks efficacy in patients with IBD. Disease-modifying antirheumatic drugs (DMARDs), such as methotrexate and sulfasalazine, are ineffective for axial disease; sulfasalazine may be effective for peripheral arthritis; this class may be considered in patients with contraindications to TNF agents.

ISSUES FOR REFERRAL
- Physical therapy can assist with treatment plan (including home regimens).
- Coordinate care with a rheumatologist for diagnosis, monitoring, and management (anti-TNF therapy).
- Management of aortic regurgitation, uveitis, spinal fractures, pulmonary fibrosis, hip joint involvement, renal amyloidosis, and cauda equina syndrome may require referral to appropriate specialty.

ADDITIONAL THERAPIES
Bisphosphonate medications if osteopenia or osteoporosis is present

SURGERY/OTHER PROCEDURES
- Evaluate for C-spine ankylosis/instability before intubation in patients with AS undergoing surgery.
- Total hip replacement with advanced hip arthritis
- Vertebral osteotomy can improve posture for patients with severe cervical or thoracolumbar flexion

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Monitor posture and range of motion with 6- to 12-month visits; increase frequency if higher disease activity.
- Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Ankylosing Spondylitis Disease Activity Score (ASDAS) can be used to measure disease activity.
- Fall prevention/evaluation
- Regular-interval monitoring of CRP or ESR
- Screening for osteopenia/osteoporosis with dual energy x-ray absorptiometry scan

PATIENT EDUCATION
- Maintain physical activity and posture.
- Swimming, tai chi, and walking are excellent activities.
- Avoid trauma/contact sports.
- Appropriate ergonomic modification of workplace
- Counsel about risk of spinal fracture.
• MedicAlert bracelet (helpful if intubation required)
• Arthritis Foundation: http://www.arthritis.org
• Spondylitis Association of America: http://www.spondylitis.org

PROGNOSIS
• Extent and rapidity of progression of ankylosis are highly variable.
• Progressive limitation of spinal mobility necessitates lifestyle modification.

COMPLICATIONS
• MSK/spine
  – Osteoporosis (13%); 10% higher risk of nonvertebral fracture in AS patients
  – Spinal fusion causing kyphosis
  – Cervical spine fracture or subluxation carries high mortality rate; fracture can occur at any
    level of ankylosed spine.
  – Cauda equina syndrome (rare)
• Pulmonary: restrictive lung disease, upper lobe fibrosis (rare)
• Cardiac: conduction defects at atrioventricular (AV) node, aortic insufficiency, aortitis,
  pericarditis (extremely rare)
• Eye: uveitis and cataracts
• Renal: IgA nephropathy, amyloidosis (<1%)
• GI: microscopic, subclinical ileal, and colonic mucosal ulcerations in up to 50% of patients,
  mostly asymptomatic

REFERENCES

ADDITIONAL READING
Diagnosis of AS is suggested by a history of inflammatory back pain, pain when supine and lasting over an hour on movement, evidence of limited chest wall expansion, restricted spinal movements in all planes, radiographic evidence of sacroiliitis, and a therapeutic response to NSAIDs.

HLA-B27 testing supports the diagnosis if clinical features are not definitive.

MRI is more sensitive at detecting SI joint inflammation than plain radiography.

Physical therapy is important in helping to maintain posture and mobility.

NSAIDs and TNF-α blockers are the mainstays of pharmacologic treatment of AS.
ANOREXIA NERVOSA
Umer Farooq, MD  •  Ayesha Fatima, MBBS

BASICS

DESCRIPTION
- An eating disorder characterized by the restriction of food intake leading to significantly low weight (less than minimally normal/expected) in the context of age, sex, developmental trajectory, and physical health, with intense fear of weight gain and body image disturbance.
- Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5), divides anorexia into two types:
  - Restricting type: not engaged in binge eating or purging behaviors for last 3 months
  - Binge eating/purging type: regularly engages in binge eating or purging behaviors (last 3 months)
- System(s) affected: cardiovascular, endocrine, metabolic, gastrointestinal, nervous, reproductive
- Severity of anorexia nervosa (AN) is based on body mass index (BMI) (per DSM-5):
  - Mild: BMI $\geq 17$ kg/m$^2$
  - Moderate: BMI 16.00 to 16.99 kg/m$^2$
  - Severe: BMI 15.00 to 15.99 kg/m$^2$
  - Extreme: BMI $< 15$ kg/m$^2$

EPIDEMIOLOGY
- Predominant age: 13 to 20 years
- Predominant sex: female $>$ male (10:1 female-to-male ratio)

Incidence
8 to 19 women/2 men per 100,000 per year

Prevalence
- 0.9% in women (0.3% in young females)
- 0.3% in men (higher in gay and bisexual men)

ETIOLOGY AND PATHOPHYSIOLOGY
- Complex relationship among genetic, biologic, environmental, psychological, and social factors that result in the development of this disorder
- Subsequent malnutrition may lead to multiorgan damage.
- Serotonin, norepinephrine, and dopamine neuronal systems are implicated.

Genetics
- There is evidence of higher concordance rates in monozygotic than in dizygotic twins.
- First-degree female relative with eating disorder increases risk 6- to 10-fold.
- One genome-wide significant locus identified for AN on chromosome 12

RISK FACTORS
- Female gender
Adolescence
Body dissatisfaction
Perfectionism
Negative self-evaluation
Academic pressure
Severe life stressors
Participation in sports or artistic activities that emphasize leanness or involve subjective scoring: ballet, running, wrestling, figure skating, gymnastics, cheerleading, weight lifting
Type 1 diabetes mellitus
Family history of substance abuse, affective disorders, or eating disorder

GENERAL PREVENTION
Prevention programs can reduce risk factors and future onset of eating disorders.
- Target adolescents and young women 15 years of age or older.
- Encourage realistic and healthy weight management strategies and attitudes.
- Promote self-esteem.
- Reduce focus on thin as ideal.
- Decrease co-occurring anxiety/depressive symptoms and improve stress management.

COMMONLY ASSOCIATED CONDITIONS
- Mood disorder—major depressive disorder
- Anxiety disorders—social phobia, obsessive-compulsive disorder, posttraumatic stress disorder
- Substance use disorder
- High rates of cluster C personality disorders

DIAGNOSIS

HISTORY
- Onset may be insidious or stress related.
- Patient unlikely to self-identify problem (lack of insight into the illness); corroborate with parent/relative.
- Restriction of energy intake relative to requirement, leading to significantly low body weight in the context of age, sex, developmental trajectory, and physical health
- Fear of weight gain and/or distorted body image
- Report feeling fat even when emaciated
- Preoccupation with body size, weight control
- Elaborate food preparation and eating rituals.
- Other possible signs and symptoms:
  - Extensive exercise
  - Amenorrhea (primary or secondary)
  - Weakness, fatigue, cognitive impairment
  - Cold intolerance
  - Constipation, bloating, early satiety
  - Growth arrest, delayed puberty
  - History of fractures (decreased bone density)
Screening
- Clinician-administered eating disorder screen for primary care to identify patients with eating disorders
  - Are you satisfied with your eating patterns? (No is abnormal.)
  - Do you ever eat in secret? (Yes is abnormal.)
  - Does your weight affect the way you feel about yourself? (Yes is abnormal.)
  - Have any members of your family suffered with an eating disorder? (Yes is abnormal.)
  - Do you currently suffer with or have you ever suffered in the past with an eating disorder? (Yes is abnormal.)

PHYSICAL EXAM
- May be normal
- Abnormal vital signs: hypothermia, bradycardia, orthostatic hypotension
- Body weight <85% of expected
- Cardiac: dysrhythmias, midsystolic click from mitral valve prolapse
- Skin/extremities: dry skin; lanugo hair on extremities, face, and trunk; hair loss; edema
- Neurologic and abdominal exams: to rule out other causes of weight loss and vomiting
- Gynecologic: amenorrhea

DIFFERENTIAL DIAGNOSIS
- Hyperthyroidism, adrenal insufficiency
- Inflammatory bowel disease, malabsorption
- Immunodeficiency, chronic infections
- Uncontrolled diabetes
- Central nervous system lesion
- Bulimia, body dysmorphic disorder
- Depressive disorders with loss of appetite
- Anxiety disorder, food phobia
- Conversion disorder

DIAGNOSTIC TESTS & INTERPRETATION
- Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the DSM-5 criteria.
- Most findings are related directly to starvation and/or dehydration. All findings may be within normal limits.
- Screening tools:
  - SCOFF questionnaire (1)[B]
  - Eating Disorder Screen for Primary Care

Initial Tests (lab, imaging)
- Complete blood count: anemia, leukopenia, thrombocytopenia
- Low-serum luteinizing hormone, follicle-stimulating hormone; low-serum testosterone in men
- Thyroid function tests: low thyroid-stimulating hormone with normal T₃/T₄
- Liver function tests: abnormal liver enzymes
- Chem 7: altered blood urea nitrogen, creatinine clearance; electrolyte disturbances
- Hypoglycemia, hypercholesterolemia, hypercortisolemia, hypophosphatemia
- Low vitamin D and hypocalcemia
- 12-Lead electrocardiogram to assess for prolonged QT interval
If underweight for >6 months: dual energy x-ray absorptiometry of bone to assess for diminished bone density

**Test Interpretation**
- Osteoporosis/osteopenia, pathologic fractures
- Sick euthyroid syndrome, dehydration
- Cardiac impairment
- AN may exist concurrently with chronic medical disorders.

**TREATMENT**

**GENERAL MEASURES**
- Initial treatment goal geared to weight restoration; most managed as outpatients (OPs)
- OP treatment:
  - Interdisciplinary team (primary care physician, mental health provider, dietitian)
  - Average weekly weight gain goal: 0.5 to 1.0 kg, with stepwise increase in calories
  - Cognitive-behavioral therapy (CBT), interpersonal psychotherapy, motivational interviewing, family-based therapy
  - Focus on health, not weight gain alone.
  - Build trust and a treatment alliance.
  - Involve the patient in establishing diet and exercise goals.
  - Challenge fear of uncontrolled weight gain; help the patient to recognize feelings that lead to disordered eating.
  - In chronic cases, goal may be to achieve a safe weight rather than a healthy weight.
- Inpatient treatment:
  - If possible, admit to a specialized eating disorders unit.
  - Monitor vital signs, electrolytes, cardiac function, edema, and weight gain.
  - Assess risk for refeeding syndrome (metabolic shift from a catabolic to anabolic state).
    - Treat by slowing nutritional intake and aggressively correcting electrolyte imbalances.
  - Initial supervised meals may be necessary.
  - Stepwise increase in activity
  - Tube feeding or total parenteral nutrition is used only as a last resort.
  - Supportive symptomatic care as needed
- Psychotherapy (e.g., CBT or family therapy) should be offered (2,3)[A].
- CBT has demonstrated effectiveness as a means of improving treatment adherence and minimizing dropout among patients with AN (4)[A].

**MEDICATION**

**First Line**
- No medications are available that effectively treat patients with AN, but pharmacotherapy may be used as an adjuvant to CBTs (5)[A].
- If medications are used, start with low doses due to increased risk for adverse effects.
- Selective serotonin reuptake inhibitors may:
  - Help to prevent relapse after weight gain
  - Treat comorbid depression or obsessive-compulsive disorder
  - Use of atypical antipsychotics is being studied with mixed findings to date. Olanzapine is
potentially beneficial as an adjuvant treatment of underweight individuals in the inpatient settings.

- Attend to black box warnings concerning antidepressants.
- The antidepressant bupropion should be avoided because it is associated with a higher incidence of seizures.

**Second Line**
- Management of osteopenia:
  - Primary treatment is weight gain.
  - Elemental calcium 1,200 to 1,500 mg/day plus vitamin D 800 IU/day
  - No indication for bisphosphonates in AN
  - Weak evidence for use of hormone-replacement therapy
- Psyllium (Metamucil) preparations to prevent constipation

**ISSUES FOR REFERRAL**
Patients with AN require an interdisciplinary team (primary care physician, mental health provider, nutritionist). An important step in management is to arrange OP mental health therapist.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Suggested physiologic values to admit: heart rate <40 beats/min, BP <90/60 mm Hg, symptomatic hypoglycemia, temperature <97.0°F (36.1°C), dehydration, other cardiovascular abnormalities, weight <75% of expected, rapid weight loss, lack of improvement while in OP therapy
- Suggested psychological indications: poor motivation/insight, lack of cooperation with OP treatment, inability to eat, need for nasogastric feeding, suicidal intent or plan, severe coexisting psychiatric disease, problematic family environment
- Suggested lab indications: potassium <3 mmol/L, prolonged QTC (>0.499 ms), urine specific gravity >1.03 or <1.01

**Pediatric Considerations**
- Children often present with nausea, abdominal pain, fullness, and inability to swallow.
- Additional indications for hospitalization: heart rate <50 beats/min, orthostatic BP, hypokalemia or hypophosphatemia, rapid weight loss even if weight not <75% below normal
- Children and adolescents should be offered family-based therapy and treatment.

**Geriatric Considerations**
Late-onset AN (>50 years of age) may be a long-term disease or triggered by death of loved one, marital discord, or divorce.
- Has a high comorbidity with depression
- Always consider other organic causes of weight loss.
- Discharge when medically stable. Arrange OP appointment with mental health provider and primary care provider.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Close follow-up until patient demonstrates forward progress in care plan
Family and individual therapy is extremely important for long-term benefits/outcomes.
CBT is helpful for the treatment of AN and may aid in the prevention of relapse.
Emphasize importance of moderate activity for health, not thinness.

**Patient Monitoring**
- Level of exercise activity
- Weigh weekly until stable and then monthly.
- Depression, suicidal ideation

**DIET**
- Dietary consultation while patient is hospitalized
- Nutritional education programs

**PATIENT EDUCATION**
- [http://www.mayoclinic.org/diseases-conditions/anorexia/home/ovc-20179508](http://www.mayoclinic.org/diseases-conditions/anorexia/home/ovc-20179508)

**PROGNOSIS**
- Prognosis: ~50% recover, 30% improve, 20% are chronically ill.
- Outcomes in men are likely better than in women.
- Mortality: 5–18% (annual mortality rate of 5 per 1,000 person-years)

**ALERT**
High risk of suicide (approximately 1 in 5 individuals with AN who died had committed suicide) (6)[A]

**COMPLICATIONS**
- Refeeding syndrome
- Cardiac arrhythmia, cardiac arrest
- Cardiomyopathy, congestive heart failure
- Delayed gastric emptying, necrotizing colitis
- Seizures, Wernicke encephalopathy, peripheral neuropathy, cognitive deficits
- Osteopenia, osteoporosis

**Pregnancy Considerations**
- Fertility may be affected.
- Behaviors may persist, decrease, or recur during pregnancy and the postpartum interval.
- Increased risk for preterm labor, operative delivery, and infants with low birth weight; anemia, genitourinary infections, and labor induction should be managed as high risk.

CODES

ICD10

- F50.01 Anorexia nervosa, restricting type
- F50.02 Anorexia nervosa, binge eating/purging type
- F50.00 Anorexia nervosa, unspecified

CLINICAL PEARLS

- “Are you satisfied with your eating patterns?” and/or “Do you worry that you have lost control over how you eat?” may help to screen those with an eating problem.
- Assess for suicide risk.
- Studies have shown patients with AN will not accept medications unless combined with psychotherapy.
- To care for a patient with AN, an interdisciplinary team that includes a medical provider, a dietitian, and a behavioral health professional is the most accepted approach.
- Family analysis is necessary for the patients with AN to determine what kind of therapy would be most helpful.
- 3 months amenorrhea is no longer a criteria needed for the diagnosis of AN.
ANTIPHOSPHOLIPID ANTIBODY SYNDROME
Krishna M. Baradhi, MD • Narothama Reddy Aeddula, MD, FACP, FASN

BASICS

DESCRIPTION
Antiphospholipid antibody syndrome (APS) is a systemic autoantibody-mediated thrombophilic disorder characterized by recurrent arterial or venous thrombosis and/or recurrent fetal loss in the presence of persistent antiphospholipid antibodies (APAs) as evidenced by lupus anticoagulant (LAC), anticardiolipin antibodies (aCL), and/or anti–β₂ glycoprotein-I (GPI) antibody. The APAs enhance clot formation by interacting with phospholipid-binding plasma proteins. The resulting APS can cause morbidity and mortality in both pregnant and nonpregnant individuals:

- Types of APS (based on clinical presentation)
  - Primary: no underlying condition evident
  - Secondary: most commonly associated with autoimmune diseases like systemic lupus erythematosus (SLE); transient APAs have been linked to certain infections, drugs, and malignancies.
  - Catastrophic APS (CAPS) a.k.a. Asherson syndrome (<1%)
    - Most severe form of disease; characterized by thrombotic microangiopathy and associated with multiorgan failure
    - High mortality if treatment is delayed

Pregnancy Considerations
- Complications include maternal venous thromboembolism, stroke, fetal demise, preeclampsia and placental insufficiency, fetal growth retardation, miscarriage, and preterm birth.
- Triple antibody positivity is considered the most noteworthy risk factor.
- Low-dose aspirin and low-molecular-weight heparin (LMWH) or unfractionated heparin are the drugs of choice in pregnancy.
- Prophylactic-dose heparin is recommended in the postpartum period (unless patient is on therapeutic anticoagulation) given high risk of thrombosis during this time. With adequate treatment, >70% of patients with APS deliver viable infants.

EPIDEMIOLOGY
- The prevalence of APAs increases with age but is not necessarily associated with a higher risk of thrombosis.
- For APS, female > male

Incidence
- Incidence of APS is around 5 new cases per 100,000 persons per year.
- In patients with positive APAs without prior risk of thrombosis, the annual incident risk of thrombosis is 0–3.8%. This risk is increased to 5.3% in those with triple positivity. 10–15% of recurrent abortions are attributable to APS.

Prevalence
Prevalence around 40 to 50 cases per 100,000 persons per year. APAs are present in 1–5% of the
general population and in ~40% of those with SLE. A higher prevalence of 10–15% is seen in those with venous thromboembolism, fetal loss, and stroke.

ETIOLOGY AND PATHOPHYSIOLOGY

- Anti–β₂-GP1 antibodies play a central role in the pathogenesis of APS. The procoagulant effect is mediated by various possible mechanisms:
  - Endothelial effects: inhibition of prostacyclin production and loss of annexin V cellular shield
  - Platelet activation resulting in adhesion and aggregation
  - Interference of innate anticoagulant pathways (such as inhibition of protein C)
  - Complement activation
- Pregnancy-related complications are also a result of autoantibody-mediated effects:
  - Interference with expression of trophoblastic adhesion molecules resulting in abnormal placentation and placental thrombosis
- Proposed mechanisms: excess production of natural antibodies, molecular mimicry due to infections, exposure of phospholipid antigens during platelet activation, cardiolipin peroxidation, and genetic predisposition
- A “second hit” by environmental factors is often required to manifest APS.

Genetics

Most cases of APS are acquired. There are a few studies of familial occurrence of aCL and LAC. A valine 247/leucine polymorphism in β₂-GP1 could be a genetic risk for the presence of anti–β₂-GP1 antibodies and APS.

RISK FACTORS

- Age >55 years in males, >65 years in females
- Cardiovascular risk factors (hypertension [HTN], hyperlipidemia, diabetes, obesity, smoking, combined oral contraceptive use)
- Underlying autoimmune disease (SLE, rheumatoid arthritis, collagen vascular disease, Sjögren syndrome, idiopathic thrombocytopenic purpura, Behçet syndrome)
- Positive APAs
- Surgery, immobilization, pregnancy

GENERAL PREVENTION

Risk factor modification: Control HTN and diabetes; smoking cessation; avoidance of oral contraceptives in high-risk patients; start thromboprophylaxis in established cases; preconception assessment

COMMONLY ASSOCIATED CONDITIONS

- Autoimmune diseases: SLE (most common), scleroderma, Sjögren syndrome, dermatomyositis, and rheumatoid arthritis
- SLE is the most common autoimmune disease associated with APS.
- Malignancy
- Infections: viral, bacterial, parasitic, and rickettsial
- Certain drugs associated with APA production without increased risk of thrombosis: phenothiazines, hydralazine, procainamide, and phenytoin
- Hemolysis, elevated liver enzymes, and low platelet count in association with pregnancy (HELLP) syndrome
Sneddon syndrome (APS variant syndrome with livedo reticularis, HTN, and stroke)

**DIAGNOSIS**

Sapporo criteria (also called Sydney criteria), revised 2006:

- At least one of the following clinical criteria:
  - Vascular thrombosis
    - ≥1 clinical episodes of arterial, venous, or small vessel thrombosis, occurring within any tissue or organ and confirmed by unequivocal imaging studies or histopathology without associated inflammation in the vessel wall
    - Superficial venous thrombosis does not meet the criteria for APS.
  - Complications of pregnancy (any one of the following):
    - ≥3 consecutive spontaneous abortions before the 10th week of pregnancy, unexplained by maternal/paternal chromosomal abnormalities or maternal anatomic/hormonal causes
    - ≥1 unexplained deaths of morphologically normal fetuses (documented by ultrasonography or by direct examination) at ≥10th week of gestation
    - ≥1 premature births of morphologically normal newborn babies at ≤34th week of pregnancy due to severe preeclampsia, eclampsia, or placental insufficiency

- AND the presence of at least one of three laboratory findings (confirmed on ≥2 occasions at least 12 weeks apart):
  - LAC detected in blood
  - Anticardiolipin IgG and/or IgM antibodies present at moderate or high levels in the blood (>40 GPL or myeloproliferative leukemia virus or >99th percentile) via a standardized enzyme-linked immunosorbent assay (ELISA)
  - Anti–β2-GP1 IgG and/or IgM antibodies in blood at a titer >99th percentile by standardized ELISA

**HISTORY**

- History of venous thromboembolism or arterial thrombosis (stroke, myocardial infarction)
- History of recurrent fetal loss or other obstetric complications
- Bleeding from thrombocytopenia if severe or acquired factor II deficiency
- Personal or family history of autoimmune disease

**PHYSICAL EXAM**

- Signs of venous thrombosis in extremities
- Skin manifestations, including a vasculitic rash in the form of palpable purpura or livedo reticularis, superficial thrombophlebitis, or lower extremity ulcers
- Livedo reticularis
- Cardiac murmurs
- Focal neurologic or cognitive deficits

**DIFFERENTIAL DIAGNOSIS**

- Thrombophilic conditions
  - Acquired: neoplastic and myeloproliferative disorders, hyperviscosity syndromes, nephrotic syndrome
Embolic disease secondary to atrial fibrillation, left ventricle dysfunction, endocarditis, cholesterol emboli
Disseminated intravascular coagulation
Paroxysmal nocturnal hemoglobinuria
Heparin-induced thrombocytopenia
Behçet syndrome
CAPS: hemolytic-uremic syndrome, thrombotic thrombocytopenic purpura, or malignant HTN

DIAGNOSTIC TESTS & INTERPRETATION

- Lupus Anti-Coagulant (LAC) assay and IgG and IGM anti cardiolipin antibody (aCL) by ELISA and anti–β2-GP1 IgG and IgM antibodies are diagnostic tests of choice.
- The LAC assay combines at least two out of three screening tests (prolongation of aPTT, dilute Russell viper venom time [dRVVT], and kaolin clotting) with two confirmatory tests.
- A weakly positive LAC result should be considered clinically important (1).
- Anti–β2-GP1 antibodies are important in the pathogenesis of thrombosis. A positive LAC assay recognizes antibodies against β2-GP1 and prothrombin.
- Although testing for antibodies to phosphatidylserine and prothrombin can help to assess the risk of thrombosis, routine evaluation for prothrombin antibodies is not recommended.
- The clinical significance of other autoantibodies (annexin V, phosphatidic acid, and phosphatidylinositol) remains unclear.
- The utility of β2-GP1 anti-domain I antibodies is being evaluated thoroughly for its diagnostic and risk stratification value.

Initial Tests (lab, imaging)

- Complete blood count, prothrombin time/international normalized ratio, activated partial thromboplastin time (aPTT), LAC, aCL, anti–β2-GP1 antibodies (2)[B]
- Prevalence of APAs in SLE ranges from 11% to 87%; hence, it is important to screen for SLE.
- Imaging is based on clinical picture, suspected sites of thrombosis, and organ involvement.

Follow-Up Tests & Special Considerations

- The results of LAC are difficult to interpret in patients treated with warfarin. Unfractionated heparin or LMWH and fondaparinux do not affect the LAC assay.
- Repeat testing at 12 weeks for persistence of APA.

Diagnostic Procedures/Other

Biopsy of the affected organ system may be necessary to distinguish from vasculitis.

Test Interpretation

Usual finding is thrombosis and minimal vascular or perivascular inflammation:
- Acute changes: capillary congestion and noninflammatory fibrin thrombi
- Chronic changes: ischemic hypoperfusion, atrophy, and fibrosis

TREATMENT

MEDICATION

First Line
Primary thromboprophylaxis: is controversial in patients with APAs and no clinical symptoms (3)[B]. Low-dose aspirin or heparin is indicated only in patients with a high risk of thrombosis as the overall risk of thrombosis is less than 4%.

Secondary thromboprophylaxis: All symptomatic, nonpregnant patients with APS need indefinite anticoagulation. The target INR depends on the severity and type of thrombosis:

- Venous thrombosis (first episode): warfarin with target INR of 2.0 to 3.0 (3)[B]
- Arterial thrombosis or recurrent venous thrombosis despite anticoagulation: warfarin with target INR 3.0 to 4.0
- LMWH and fondaparinux are alternatives.

Direct oral anticoagulants (DOACs) such as rivaroxaban, apixaban, and dabigatran; all have been approved for treatment of DVT/PE; however, studies in APS are lacking; a prospective randomized trial in 2016 of warfarin versus rivaroxaban in patients with thrombotic APS showed increase in endogenous thrombin potential in patients who switched to rivaroxaban. The 15th International Congress on Antiphospholipid Antibodies Task Force published in 2017 concluded that there is insufficient evidence to recommend DOACs in APS. DOACs may be alternatives to warfarin in patients intolerant to warfarin.

- Rituximab may be an option in severe cases, possibly in those with thrombotic microangiopathy (4,5)[B].

Danaparoid, fondaparinux, and argatroban can be considered in heparin-induced thrombocytopenia.

Statins can decrease proinflammatory and prothrombotic state in APS but are not recommended in the absence of hyperlipidemia.

Hydroxychloroquine can be added in recalcitrant APS.

Eculizumab may be useful in refractory cases.

Vitamin D deficiency/insufficiency should be corrected in all APA-positive patients, but its role in APS needs further study.

Low-dose aspirin is superior to low-dose aspirin with low-dose warfarin due to decreased bleeding risk with no differences in number of thrombosis (6).

CAPS: Anticoagulants and high-dose steroids may suffice in less severe cases. Aggressive treatment with either IVIG or plasma exchange is often required in severe cases. These measures have improved survival up to 66%.

Treatment in pregnancy:

- Patients with APAs and no prior thrombotic events should not receive thromboprophylaxis during pregnancy.
- For women with no prior history of thrombosis and ≥2 early miscarriages, treat with either 81 mg ASA alone or in combination with unfractionated heparin (5,000 to 10,000 U SC q12h) or LMWH (prophylactic dose). In those with a previous late pregnancy loss (>10 weeks’ gestation) or preterm (<34 weeks) delivery due to severe preeclampsia, a combination of ASA and heparin is recommended.
- Preconception assessment and treatment with low-dose aspirin, vitamin D, and folate should be offered in selected patients.
- In those with a history of thrombosis, low-dose ASA plus either therapeutic low-dose heparin (dosed every 8 to 12 hours to maintain mid-interval aPTT or factor Xa levels) or LMWH (therapeutic dose)
- Refractory cases: Up to 30% of patients have recurrent pregnancy loss despite the use of ASA and heparin. There is no role for warfarin due to risk of teratogenicity. Such cases are
best managed in consultation with a maternal–fetal medicine specialist.

**SURGERY/OTHER PROCEDURES**

Patients with thrombosis may require thrombectomy or an inferior vena cava filter when anticoagulation is contraindicated.

### ONGOING CARE

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Standard guidelines for monitoring to maintain INR at therapeutic goal on warfarin therapy
- Close monitoring is required during pregnancy.

**DIET**

Heart-healthy diet. Patients on warfarin should avoid foods rich in vitamin K (kale, spinach, sprouts, greens).

**PATIENT EDUCATION**
- Compliance with warfarin therapy to keep INR at goal
- Awareness of drug and diet interactions with warfarin
- Avoid oral hormonal contraceptives.

**PROGNOSIS**
- Pulmonary HTN, neurologic involvement, myocardial ischemia, nephropathy, gangrene of extremities, and CAPS are associated with a worse prognosis.
- 30% risk of recurrent thrombosis in the absence of adequate anticoagulation

**COMPLICATIONS**
- Pregnancy complications and pulmonary HTN are associated with higher morbidity and mortality.
- Thrombotic complications are the common cause of death.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- D68.61 Antiphospholipid syndrome
- D68.69 Other thrombophilia
- D68.62 Lupus anticoagulant syndrome

CLINICAL PEARLS

- APS is a multisystem autoimmune disorder with recurrent arterial/venous thrombosis, fetal loss, and positive APAs.
- Both clinical and laboratory criteria are required for diagnosis. The latter must be confirmed on two separate occasions at least 12 weeks apart.
- Thrombotic manifestations of APS require lifelong anticoagulation.
ANXIETY (GENERALIZED ANXIETY DISORDER)
Rhonda A. Faulkner, PhD ● Diana Bonaccorsi, DO

BASICS

DESCRIPTION
- A condition characterized by persistent, excessive, and difficult-to-control worry associated with significant symptoms of motor tension, autonomic hyperactivity, and/or disturbances of sleep or concentration
- System(s) affected: nervous (increased sympathetic tone and catecholamine release); secondary effects on other symptoms such as cardiac (tachycardia), pulmonary (dyspnea), and gastrointestinal (GI) (nausea, irregular bowels)

EPIDEMIOLOGY

Prevalence
- 12-month prevalence rate: 1.8%
- Lifetime prevalence rate in United States 5.1–11.9%
- Elderly prevalence as high as 7–10%
- Onset can occur any time in life but is typically during adulthood; median age of onset in the United States is 31 years.
- Predominant sex: female > male (2:1)
- Generally recurrent and chronic in nature; gradual in onset; fluctuates in severity; complete remission less likely

ETIOLOGY AND PATHOPHYSIOLOGY
- May be mediated by abnormalities of neurotransmitter systems (i.e., serotonin, norepinephrine, and γ-aminobutyric acid [GABA])
- Associated with altered regional brain function (increased activity in the amygdala and prefrontal cortex)

Genetics
- Strongly linked to depression in heritability studies
- A variant of the serotonin transporter gene (5HT1A) or other genes may contribute to both conditions.

RISK FACTORS
- Adverse life events
- Family history
- Chronic physical illness
- Lack of social support
- Poverty
- Comorbid psychiatric disorders

GENERAL PREVENTION
- Physical activity and cardiorespiratory fitness are associated with decreased generalized anxiety and depression.
Cognitive-behavioral therapy (CBT) and parental intervention in children with early anxiety may protect against the development of GAD (2).

COMMONLY ASSOCIATED CONDITIONS
- Major depressive disorder (>60%), dysthymia, bipolar disorder, schizophrenia
- Alcohol/drug abuse
- Cigarette smoking in adolescence
- Panic disorder, agoraphobia, simple phobia, social anxiety disorder, anorexia nervosa, posttraumatic stress disorder (PTSD), obsessive-compulsive disorder (OCD), attention deficit hyperactivity disorder (ADHD)
- Somatoform and pain disorders

DIAGNOSIS

HISTORY
- Diagnosis is primarily made through history taking. Pathologic anxiety must be distinguished from normal anxiety reactions.
- Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) criteria are as follows:
  - Symptoms of excessive anxiety and worry must occur more often than not for at least 6 months.
  - Patient finds it difficult to control the worry.
  - At least three additional criteria are required for diagnosis of GAD in adults; only one is required in children.
    - Restlessness or feeling keyed up or on edge
    - Easily fatigued
    - Difficulty concentrating or mind going blank
    - Irritability
    - Muscle tension
    - Sleep disturbances (difficulty falling or staying asleep)
  - Persistent worry must cause significant distress or impairment in social, occupational, or other areas of functioning.
  - Focus of anxiety and worry is not consistent with or limited to the occurrence of other types of psychiatric disorders and is not directly related to PTSD.
  - Symptoms are not the result of a substance, another medical condition, or other DSM-5 diagnosis.

PHYSICAL EXAM
- Useful for identifying other differential diagnosis (see below). No specific physical findings in GAD, but patient may exhibit irritability, bitten nails, tremor, or clammy hands.

DIFFERENTIAL DIAGNOSIS
- Cardiovascular: ischemic heart disease, valvular heart disease (mitral valve prolapse), cardiomyopathies, arrhythmias, congestive heart failure
- Respiratory: asthma, chronic obstructive pulmonary disease, pulmonary embolism
- Central nervous system (CNS): stroke, seizures, dementia, migraine, vestibular dysfunction, neoplasms
- Metabolic and hormonal: hyper- or hypothyroidism, pheochromocytoma, adrenal insufficiency, Cushing syndrome, hypokalemia, hypoglycemia, hyperparathyroidism
- Drug-induced anxiety: alcohol, sympathomimetics (cocaine, amphetamine, caffeine), corticosteroids, herbas (ginseng)
- Withdrawal: alcohol, sedative-hypnotics
- Psychiatric: other disorders (e.g., panic disorder, OCD, PTSD, social phobia, adjustment disorder, and somatization disorder)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Laboratory tests are normal. Initial tests may include thyroid-stimulating hormone, complete blood count, basic metabolic panel, urine drug screen, and ECG.
- GAD-2: two-question self-reporting scale (22% positive predictive value [PPV]/78% negative predictive value [NPV])
- PHQ-4 provides a very brief screen for both anxiety and depression (2).

**Diagnostic Procedures/Other**

Psychological testing
- GAD-7: five additional questions; provides more detailed information for treatment (29% PPV/71% NPV); also may be indicative of panic disorder (GAD-7: 29% PPV/71% NPV)
- Hamilton Anxiety Scale (HAM-A), Anxiety Disorders Interview Schedule (ADIS-IV)
- In pediatric populations: ADIS-IV Parent and Child Version, Multidimensional Anxiety Scale for Children (MASC), Screen for Child Anxiety Related Emotional Disorders (SCARED)

**TREATMENT**

**GENERAL MEASURES**
- Assess for suicidality given increased risk.
- Identify and treat coexisting substance abuse and other psychiatric conditions.
- Psychoeducation recommended for all patients in addition to physical exercise and mindfulness-based stress reduction approaches.
- Start early because delayed treatment may result in poorer clinical outcomes compared with patients treated within 1 year of symptom onset.
- Consider utilizing self-reported measures at each visit to quantify the level of anxiety as well as to track severity and treatment response (i.e., GAD-7).
- Remission may not occur until 4 to 6 months into treatment. Treat for at least 12 months.
- Persistence with therapy necessary to achieve maximum benefit and ensure sustained improvement
- Psychotherapeutic approaches
  - Psychological treatments are effective in treating GAD: number needed to treat (NNT) = 2 (3)[A].
  - CBT: most well-studied psychological treatment; may improve comorbid conditions such as depression; treatment of choice when available (2)[A]
  - Relaxation/mindfulness training (2)[A]
  - Psychodynamic psychotherapy: Treatment is focused on patient discovering and verbalizing unconscious conflicts (2)[C].
MEDICATION

First Line

- Selective serotonin reuptake inhibitor (SSRI) and SNRI antidepressants have demonstrated efficacy, are well-tolerated, do not cause abuse/dependence, and treat comorbid depression. Data to compare between agents are limited (4)[A].
- Medication selection based on side-effect profile, drug-drug interactions, and/or patient treatment history/preference.
- In general, with SSRIs/serotonin-norepinephrine reuptake inhibitors (SNRIs), start at the lowest available dose, up-titrate every 2 to 4 weeks, and use highest tolerated FDA-approved dose for at least 4 to 6 weeks before deeming ineffective. Then, consider switching to a different SSRI/SNRI.
- Switching between medications without adequate dose or duration of therapy can lead to ineffective treatment.
- Taper all doses gradually to discontinue.
- Common side effects of SSRIs may include nausea, diarrhea, insomnia, agitation or sedation, drug interactions, weight gain, and sexual side effects (decreased libido, delayed orgasm).
- Common side effects of SNRIs may include nausea, dizziness, insomnia, sedation, constipation, sweating, and some may cause blood pressure elevation.
- SSRIs: Escitalopram (Lexapro): initially 10 mg/day; may titrate to a maximum of 20 mg/day (5)[A]
- SNRIs:
  - Duloxetine (Cymbalta): initially 30 mg/day; may titrate by 30 mg/day qwk to a maximum of 120 mg/day; doses >60 mg/day rarely more effective (5)[A]
  - Venlafaxine XR (Effexor XR): initially 37.5 to 75.0 mg; may titrate up by 75 mg every 4 days to a maximum of 225 mg/day (5)[A]
- Pregabalin (Lyrica): decreases anxiety scores and reduces relapse at 75 to 300 mg BID; may cause less sexual dysfunction and sleep disruption than SSRIs. Taper to discontinue; has rapid onset of action. (Off-label use) (5)[A].

Second Line

- Sertraline (Zoloft): initially 25 mg/day; may titrate by 25 to 50 mg/day qwk to a maximum of 200 mg/day (5)[B]
- Azapirones: buspirone (BuSpar): less risk of dependence; 15 mg/day divided BID–TID initially; maximum of 60 mg/day divided BID–TID (5)[B]
- Fluoxetine (Prozac): 10/20 mg/day; may titrate up to 60 mg/day (Off-label use) (5)[B].
- Mirtazapine (Remeron): 15 mg nightly; titrate in increments of 15 mg weekly; maximum dose 45 mg daily; use as monotherapy or as adjunct to SSRI; most common side effect is drowsiness (off-label use) (5)[B].
- Paroxetine (Paxil): initially 10 to 20 mg/day; may titrate by 10 mg/day qwk to a maximum of 50 mg/day (no added benefit >20 mg/day). Efficacious but poorly tolerated (5)[A].
- Quetiapine (Seroquel): optimal dose 150 mg/day. 2nd-generation antipsychotic. Efficacious but less well tolerated than SSRIs. Consider using as augmentation (5)[A].
- Citalopram (Celexa) likely has efficacy for GAD but does not have FDA indication.
- Benzodiazepines: efficacious in the short term but less effective long term, risk for dependence and abuse (4,5)[A]
  - Clonazepam (Klonopin): 0.25 mg BID; may increase to 4 mg/day divided BID
– Diazepam (Valium): 2 to 5 mg BID–QID; may increase to a maximum of 40 mg/day
– Lorazepam (Ativan): 0.5 mg BID–TID; may increase to 6 mg/day divided TID
– Alprazolam (Xanax): 0.25 mg TID; may increase to 4 mg/day

Hydroxyzine (Vistaril, Atarax): CNS depressant, antihistamine, anticholinergic; decreased risk of dependence compared with benzodiazepines: usual dose: 50 to 100 mg PO QID; limit use in the elderly (3][B].

Geriatric Considerations
- Avoid tricyclic antidepressants and long-acting benzodiazepines; benzodiazepines may cause delirium.
- Pregabalin may cause dizziness and somnolence.

Pediatric Considerations
- CBT is first-line treatment for pediatric patients with mild to moderate GAD.
- CBT in combination with SSRIs is first-line treatment with severe GAD in pediatric population.
- Black box warning (SSRIs): Antidepressants increase the risk of suicidal thinking and behavior in children, adolescents, and young adults.
- However, studies have also shown increase in suicide attempts in adolescents after SSRI discontinuation.
- SSRIs and SNRIs have all been shown to be effective in pediatric population.
- SSRIs are first-line choice among medications because they are associated with greater side effect tolerance among children and adolescents.
- Anxiety and ADHD often co-occur. Treat the more debilitating first and consider using nonstimulating medications.

Pregnancy Considerations
- Buspirone: Category B: secreted in breast milk; inadequate studies to assess risk
- Benzodiazepines: Category D: may cause lethargy and weight loss in nursing infants; avoid breastfeeding if the mother is taking chronically or in high doses.
- SSRIs: If possible, taper and discontinue. After 20 weeks’ gestation, there is increased risk of pulmonary hypertension; mild transient neonatal syndrome of CNS; and motor, respiratory, and GI signs. Studies regarding risk of autism show mixed results. Most are Category C, with the exception of: – Paroxetine: Category D: conflicting evidence regarding the risk of congenital cardiac defects and other congenital anomalies in the 1st trimester
  – Hydroxyzine: Category C: Case reports of neonatal withdrawal exist.

ALERT

Precautions
– Benzodiazepines: age >65 years, respiratory disease/sleep apnea, contraindicated with narrow-angle glaucoma, precaution with open-angle glaucoma; sudden discontinuation increases seizure risk. Long-term use has potential for tolerance and dependence; use with caution in patients with history of substance abuse.
– Buspirone: hepatic and/or renal dysfunction; monoamine oxidase inhibitor (MAOI) treatment
– SSRIs: Use caution in those with comorbid bipolar disorder; may increase risk of serotonin syndrome, especially in combination with other serotonergic drugs

ISSUES FOR REFERRAL
Concomitant depression, refractory anxiety, or other comorbidities may warrant a psychiatric evaluation in light of increased suicide risk.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Patients frequently engage in complementary and alternative medicine (CAM); providers should be familiar with common therapies.
- Probable benefit but more study needed on several complementary therapies including acupuncture, yoga, massage, tai chi, and aromatherapy (6)[A]
- Kava: some evidence for benefit over placebo in mild to moderate anxiety, but concern regarding potential hepatotoxicity. Safety is potentially affected by manufacturing quality, plant part used, dose, and interactions with other substances (6)[A].
- Strong evidence to support regular physical activity to relieve anxiety symptoms (6)[A]
- Small study showed possible benefit from repetitive transcranial magnetic stimulation (rTMS) to the right dorsal lateral prefrontal cortex for pharmacotherapy treatment refractory patients.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Patients at risk for suicide should be treated as inpatients; may be considered as well for patients with substantial interference in daily function.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Clinical follow-up with patient every 6 months is recommended.
- Follow up within 2 to 4 weeks from starting new medications.
- Medications should be continued past the initial period of response and recommend continued treatment for 12 months.
- Monitor mental status on benzodiazepines and avoid drug dependence or abrupt discontinuation.
- Monitor all patients for suicidal ideation but especially those on SSRIs and SNRIs.

**DIET**

- Limit caffeine intake.
- Avoid alcohol (drug interactions, high rate of abuse, potential for increased anxiety) and nicotine.

**PATIENT EDUCATION**

- Regular exercise may be beneficial for both anxiety and comorbid conditions.
- Psychoeducation regarding normal versus pathologic anxiety, the fight or flight response, and the physiology of anxiety can be extremely helpful.

**PROGNOSIS**

- Probability of recovery is approximately 40–60%, but relapse is common.
- Comorbid psychiatric disorders and poor relationships with spouse or family make relapse more likely.

CODES

ICD10

F41.1 Generalized anxiety disorder

CLINICAL PEARLS

- Psychiatric comorbidities, especially depression, are extremely common with GAD; patients are at increased risk for suicidality.
- CBT and SSRIs (possibly in combination) are the treatments of choice.
- Start medication at low doses, with careful titration to full therapeutic dosing, helps minimize side effects while maximizing efficacy.
- Benzodiazepines may be used initially but should be tapered and withdrawn if possible.
- CAM use is common, and certain therapies may be effective.
AORTIC VALVULAR STENOSIS
Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION
Aortic stenosis (AS) is a narrowing of the aortic valve area causing obstruction to left ventricular (LV) outflow. The disease has a long asymptomatic latency period, but development of severe obstruction or onset of symptoms such as syncope, angina, and congestive heart failure (CHF) are associated with a high mortality rate without surgical intervention.

EPIDEMIOLOGY
AS is the most common primary valve disease leading to surgery or catheter intervention in Europe and North America, with a growing prevalence due to the aging population (1). Cause by age at presentation:
- <30 years: congenital
- 30 to 65 years: congenital or rheumatic fever (RF)
- >65 years: degenerative calcification of aortic valve

Prevalence
- Affects 1.3% of population 65 to 74 years old, 2.4% 75 to 84 years old, 4% >84 years old
- Bicuspid aortic valve: 1–2% of population. Bicuspid aortic valve predisposes to development of AS at an earlier age.

ETIOLOGY AND PATHOPHYSIOLOGY
- Progressive aortic leaflet thickening and calcification results in LV outflow obstruction. Obstruction causes increased afterload and, over time, decreased cardiac output.
- Increase in LV systolic pressure is required to preserve cardiac output; this leads to development of concentric LV hypertrophy (LVH). The compensatory LVH preserves ejection fraction but adversely affects heart functioning.
  - LVH impairs coronary blood flow during diastole by compression of coronary arteries and reduced capillary ingrowth into hypertrophied muscle.
  - LVH results in diastolic dysfunction by reducing ventricular compliance.
- Diastolic dysfunction necessitates stronger left atrial (LA) contraction to augment preload and maintain stroke volume. Loss of LA contraction by atrial fibrillation can induce acute deterioration.
- Diastolic dysfunction may persist after relief of AS due to the presence of interstitial fibrosis.
- Angina: increased myocardial demand due to higher LV pressure. Myocardial supply is compromised due to LVH.
- Syncope (exertional): can be multifactorial from inability to augment cardiac output due to the fixed obstruction to LV outflow; arrhythmias; or most commonly, abnormal baroreceptor response resulting in failure to appropriately augment blood pressure.
- Heart failure: Eventually, LVH cannot compensate for increasing afterload resulting in high LV pressure and volume, which are accompanied by an increase in LA and pulmonary pressures.
- Degenerative calcific changes to aortic valve (2)
Mechanism involves mechanical stress to valve leaflets as well as atherosclerotic changes to the valve tissue. Bicuspid valves are at higher risk for mechanical stress.

Early lesions: subendothelial accumulation of oxidized LDL and macrophages and T lymphocytes (inflammatory response)

Disease progression: Fibroblasts undergo transformation into osteoblasts; protein production of osteopontin, osteocalcin, and bone morphogenic protein-2 (BMP-2), which modulates calcification of leaflets

- Congenital: unicuspid valve, bicuspid valve, tricuspid valve with fusion of commissures, hypoplastic annulus
- RF: chronic scarring with fusion of commissures

RISK FACTORS
- Congenital unicommissural valve or bicuspid valve
  - Unicommissural valve: Most cases were detected during childhood.
  - Bicuspid valve: predisposes to the development of AS earlier in adulthood (4th to 5th decade) compared to tricuspid valve (6th to 8th decade)
- RF
  - Prevalence of chronic rheumatic valvular disease has declined significantly in the United States.
  - Most cases are associated with mitral valve disease.
- Degenerative calcific changes
  - Most common cause of acquired AS in the United States
  - Risk factors are similar to that of coronary artery disease (CAD) and include the following: hypercholesterolemia, hypertension, smoking, male gender, age, and diabetes mellitus.

COMMONLY ASSOCIATED CONDITIONS
- CAD (50% of patients)
- Hypertension (40% of patients): results in “double-loaded” left ventricle (dual source of increased afterload as a result of obstruction from AS and hypertension)
- Aortic insufficiency (common in calcified bicuspid valves and rheumatic disease)
- Mitral valve disease: 95% of patients with AS from RF also have mitral valve disease.
- LV dysfunction and CHF
- Acquired von Willebrand disease: Impaired platelet function and decreased vWF results in bleeding (ecchymosis and epistaxis) in 20% of AS patients. Severity of coagulopathy is directly related to severity of AS.
- Gastrointestinal arteriovenous malformations (AVMs)
- Cerebral or systemic embolic events due to calcium emboli

DIAGNOSIS

HISTORY
- Primary symptoms: angina, syncope, and heart failure. Angina is the most frequent symptom. Syncope is often exertional. Heart failure symptoms include fatigue, exertional dyspnea, orthopnea, paroxysmal nocturnal dyspnea, and shortness of breath.
- Palpitations
- Neurologic events (transient ischemic attack or cerebrovascular accident) secondary to
Geriatric patients may have subtle symptoms such as fatigue and exertional dyspnea.

Note: Symptoms do not always correlate with valve area (severity of AS) but most commonly occur when aortic valve area is <1 cm², jet velocity is >4.0 m/s, or the mean transvalvular gradient is ≥40 mm Hg.

**PHYSICAL EXAM**

- Auscultation
  - Harsh, systolic crescendo–decrescendo murmur is best heard at 2nd right sternal border and radiates into the carotid arteries. Peak of murmur correlates with severity of stenosis; later peaking murmur suggests greater severity.
  - High-pitched blowing diastolic murmur suggests associated aortic insufficiency.
  - Paradoxically split S₂ or absent A₂. Note: Normally split S₂ reliably excludes severe AS.
  - S₄ due to stiffening of the left ventricle
- Other associated signs include pulsus parvus et tardus: decreased and delayed carotid upstroke. LV heave; findings of CHF: pulmonary and/or lower extremity edema

**DIFFERENTIAL DIAGNOSIS**

- Mitral regurgitation: High-frequency, pansystolic murmur, best heard at the apex, often radiates to the axilla.
- Hypertrophic obstructive cardiomyopathy: also systolic crescendo–decrescendo murmur but best heard at left sternal border and may radiate into axilla. Murmur intensity increases by changing from squatting to standing and/or by Valsalva maneuver.
- Discrete fixed subaortic stenosis: 50–65% has associated cardiac deformity (patent ductus arteriosus [PDA], ventricular septal defect [VSD], aortic coarctation).
- Aortic supravalvular stenosis: Williams syndrome, homozygous familial hypercholesterolemia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Chest x-ray (CXR)
  - May be normal in compensated, isolated valvular AS
  - Boot-shaped heart reflective of concentric hypertrophy
  - Poststenotic dilatation of ascending aorta and calcification of aortic valve (seen on lateral PA CXR)
- ECG: often normal ECG (ECG is nondiagnostic), or may show LVH, LA enlargement, and nonspecific ST- and T-wave abnormalities
- Echo indications
  - Initial workup
    - Doppler echocardiogram: primary test in the diagnosis and evaluation of AS
    - Assesses valve anatomy and severity of disease
    - Assesses LV wall thickness, size, and function, and pulmonary artery pressure
    - In known AS and changing signs/symptoms
    - In known AS and pregnancy due to hemodynamic changes of pregnancy
  - Echo findings
    - Aortic valve thickening, calcification
    - Decreased aortic valve excursion
    - Reduced aortic valve area
– Transvalvular gradient across aortic valve
– LVH and diastolic dysfunction
– LV ejection fraction
– Wall-motion abnormalities suggesting CAD
– Evaluate for concomitant aortic insufficiency or mitral valve disease.

• AS severity based on echo values (2)
  – Stage A (at risk): bicuspid aortic valve, sclerosis, or other congenital abnormality; mean pressure gradient: 0 mm Hg; jet vel. <2 m/s
  – Stage B (progressive): bicuspid or trileaflet valve
    o Mild: mean pressure gradient: <20 mm Hg; jet vel. 2.0 to 2.9 m/s
    o Moderate: mean pressure gradient: 20 to 40 mm Hg; jet vel. 3.0 to 3.9 m/s
  – Stage C (asymptomatic severe AS):
    o C1 (without LV dysfunction): AVA ≤1.0 or AVAi ≤0.6 cm²/m²; mean pressure gradient: 40 to 60 mm Hg; jet vel. ≥4 to 5 m/s
    o C2 (with LV dysfunction): AVA ≤1.0 or AVAi ≤0.6 cm²/m²; mean pressure gradient: ≥40 mm Hg; jet vel. ≥4 m/s
  – Stage D (symptomatic severe AS):
    o D1 (high gradient): AVA ≤1.0 cm²; mean pressure gradient: >40 mm Hg; jet vel. >4 m/s
    o D2 (low flow/low gradient with reduced EF <50%): AVA ≤1.0 cm²; mean pressure gradient: <40 mm Hg; jet vel. <4 m/s
    o D3 (low gradient, normal EF ≥50% or paradoxical low-flow severe AS): AVA ≤1.0 cm²; AVAi ≤0.6 cm²/m² and stroke volume index <35 mL/m²; mean pressure gradient: <40 mm Hg; jet vel. <4 m/s

Diagnostic Procedures/Other
• Exercise stress testing
  – Asymptomatic patients with severe AS: helpful to uncover subtle symptoms or changes, abnormal BP (increase ≤20 mm Hg), and ECG changes (ST depressions). 1/3 of patients develop symptoms with exercise testing; STOP testing at this point.
  – Symptomatic patients: DO NOT perform exercise stress testing because it may induce hypotension or ventricular tachycardia.
  – CHF patients: Dobutamine stress echocardiography is reasonable to evaluate patients with low-flow/low-gradient AS and LV dysfunction.
• Cardiac catheterization
  – Perform prior to aortic valve replacement (AVR) in patients with suspected CAD. Determines need for coronary artery bypass graft (CABG). If unambiguous diagnosis of AS, perform only coronary angiography.
  – Can also use if noninvasive testing is inconclusive or if there is discrepancy between severity of symptoms and findings on echo
  – Measures transvalvular flow and transvalvular pressure gradient, which facilitates calculation of effective valve area
  – Hemodynamic measurements with infusion of dobutamine can be useful for evaluation of patients with low-flow/low-gradient AS and LV dysfunction.

Test Interpretation
• Aortic valve: nodular calcification on valve cusps (initially at bases), cusp rigidity, cusp
thickening, and fibrosis
- LVH, myocardial interstitial fibrosis
- 50% incidence of concomitant CAD

TREATMENT

MEDICATION
- No effective medical therapy for severe or symptomatic AS
- Prevention: currently no recommended medical therapy. Statins have been thought to slow progression if initiated during mild disease. However, this has not been supported by large, randomized controlled trials.
- Antibiotic prophylaxis against recurrent RF is indicated for patients with rheumatic AS (penicillin G 1,200,000 U IM q4wk; duration varies with age and history of carditis).
- Antibiotic prophylaxis is no longer indicated for prevention of infective endocarditis.
- Comorbidities: hypertension: angiotensin-converting enzyme (ACE) inhibitors, start with low dose and increase cautiously. Be cautious of vasodilators, which may cause hypotension.

SURGERY/OTHER PROCEDURES
- AVR is recommended for most symptomatic patients with evidence of significant AS on echocardiography (3).
- Indications for AVR surgery:
  - Symptomatic and severe high-gradient AS by history or exercise testing (2)[B] when surgical risk is low or intermediate
  - Asymptomatic, severe AS and LVEF <50% (2)[B]
  - Severe AS (stage C or D) when undergoing other cardiac surgery (2)[B]
- AVR surgery is reasonable in patients who are:
  - Asymptomatic with severe AS (C1) with jet vel. ≥5 m/s and low surgical risk, decreased exercise tolerance, or have an exercise fall in blood pressure (2)[B]
  - Symptomatic stage D2, with a low-dose dobutamine stress with jet vel. ≥4.0 m/s or mean pressure gradient ≥40 mm Hg with ≤1.0 cm² at any dobutamine dose (2)[B]
  - Symptomatic stage D3 with LVEF >50% if clinical and hemodynamic data support valve obstruction as likely cause of symptoms (2)[C]
  - Stage B who are undergoing other cardiac surgery, or asymptomatic stage C1 with rapid disease progression and low surgical risk (2)[C]

ALERT
Note: If the aortic valve area is >1.5 cm² and the gradient is <15 mm Hg, there is no benefit from AVR.

- Transcatheter AVR (TAVR) offers a less invasive option for some patients (1).
  - For those who are high at surgical risk and considered inoperable, TAVR has demonstrated superiority to medical therapy.
  - For those who are high at surgical risk, TAVR has demonstrated noninferiority to surgical AVR (1).
  - For those who are intermediate at surgical risk, TAVR may emerge as a reasonable alternative to surgical risk, although this indication has not yet been approved in the United
States.
- Valve-in-valve TAVR can be considered in high-risk patients with failed surgically implanted bioprosthetic valves.
- Percutaneous balloon valvuloplasty may have role in palliation or as a bridge to valve replacement in hemodynamically unstable or high-risk patients but is not recommended as an alternative to valve replacement.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Advise patients to immediately report symptoms referable to AS.
- Asymptomatic patients: yearly history and physical
- Serial ECHO: yearly for severe AS, every 1 to 2 years for moderate AS, every 3 to 5 years for mild AS

**PATIENT EDUCATION**

Physical activity limitations
- Asymptomatic mild AS: no restrictions
- Asymptomatic moderate to severe AS: Avoid strenuous exercise. Consider exercise stress test prior to starting exercise program.

**PROGNOSIS**
- Although survival in asymptomatic patients is comparable to that in age- and sex-matched control patients, it decreases rapidly after symptoms appear (3).
- 25% mortality per year in symptomatic patients who do not undergo valve replacement; average survival is 2 to 3 years without AVR surgery.
- Median survival in symptomatic AS: heart failure: 2 years; syncope: 3 years; angina: 5 years
- Perisurgical mortality: AVR surgery has 4% mortality rate; AVR + CABG has 6.8% mortality rate.
- Adverse postoperative prognostic factors: age, heart failure New York Heart Association (NYHA) class III/IV, cerebrovascular disease, renal dysfunction, CAD

**REFERENCES**

ICD10

- I35.0 Nonrheumatic aortic (valve) stenosis
- I06.0 Rheumatic aortic stenosis
- Q23.0 Congenital stenosis of aortic valve

**CLINICAL PEARLS**

- AS is diagnosed on physical exam by a systolic crescendo–decrecendo murmur and delayed and diminished pulses.
- Symptomatic AS most commonly presents as angina, syncope, and heart failure.
- Symptomatic AS has a very poor prognosis, unless treated with surgical intervention.
APPENDICITIS, ACUTE
Cragin D. Currence, MD • Caleb J. Mentzer, DO

BASICS

DESCRIPTION
- Acute inflammation of the appendix
- Arising from the base of the cecum in right lower quadrant (RLQ), the appendix can be anterior, posterior, medial, or lateral to the cecum as well as in the pelvis. Vascular supply provided by appendicular artery, a branch of the ileocolic artery; nerve supply derived from the superior mesenteric plexus
- Most common cause of acute surgical abdomen

EPIDEMIOLOGY
- Predominant age: 10 to 30 years; rare in infancy
- Predominant sex: slight male predominance
  - Ages 10 to 30 years: male > female (3:2)
  - Age >30 years: male = female

Incidence
- 1 case per 1,000 people per year
- Lifetime incidence 1 in every 15 people (7%)

Pregnancy Considerations
- Most common extrauterine surgical emergency
- Incidence similar in pregnancy
- Higher rate of perforation; more likely to present with peritonitis

ETIOLOGY AND PATHOPHYSIOLOGY
Obstruction of the appendiceal lumen is thought to lead to distention, ischemia, and bacterial overgrowth. Without intervention, appendicitis can lead to perforation and subsequent abscess formation or generalized peritonitis. Causes of obstruction:
- Fecaliths (most common)
- Lymphoid tissue hyperplasia (in children)
- Vegetable, fruit seeds, and other foreign bodies
- Intestinal worms (ascarids)
- Strictures, fibrosis, neoplasms

Genetics
First-degree relative with history of appendicitis increases risk; no direct genetic link has been found.

RISK FACTORS
Adolescent males, familial tendency, intra-abdominal tumors
DIAGNOSIS

- Diagnosis relies on history and physical examination with supporting laboratory studies and imaging.
- Scoring systems
  - Supplement MASS in female patients with additional investigations (e.g., abdominal ultrasound or laparoscopy).
  - Migratory right iliac fossa pain (1 point)
  - Nausea/vomiting (1 point)
  - Anorexia (1 point)
  - Tenderness in right iliac fossa (2 points)
  - Rebound tenderness in right iliac fossa (1 point)
  - Elevated temperature (1 point)
  - Leukocytosis (2 points)
  - A MASS score >7 suggests appendicitis without the need for further imaging.
- A cutoff point of 6 for the MASS score yields higher sensitivity but is also associated with a higher negative appendectomy rate (normal appendix).
- Pediatric Appendicitis Score—helps predict the likelihood of acute appendicitis (diagnosis is still clinical)

HISTORY

- Classic history is vague periumbilical pain, followed by anorexia, nausea, and vomiting. Over the next 4 to 48 hours, pain migrates to the RLQ.
- Only 50% of patients present with a classic history.
- Pain before vomiting (~100% sensitive), abdominal pain (~100%), pain migration (50%)
- Anorexia (~100%), nausea (90%), vomiting (75%), obstipation
- Atypical symptoms and pain suggest a retrocecal or pelvic appendix.

PHYSICAL EXAM

- Fever; temperature >100.4°F (may be absent); tachycardia
- RLQ tenderness; maximal tenderness at McBurney point (1/3 the distance from the anterior superior iliac spine to the umbilicus)
- Voluntary and involuntary guarding
- Rovsing sign: RLQ pain with palpation of left lower quadrant
- Psoas sign: pain with right thigh extension (retrocecal appendix)
- Obturator sign: pain with internal rotation of flexed right thigh (pelvic appendix); local and suprapubic pain on rectal exam (pelvic appendix)
- Pelvic and rectal exams are helpful to assess other causes of lower abdominal pain (e.g., pelvic inflammatory disease, prostatitis).
- Serial exams can be useful in indeterminate cases.

DIFFERENTIAL DIAGNOSIS

- Gastrointestinal
  - Gastroenteritis, inflammatory bowel disease
– Diverticulitis, ileitis
– Cholecystitis, pancreatitis
– Intussusception, volvulus

● Gynecologic
  – Pelvic inflammatory disease, ectopic pregnancy
  – Ovarian cyst, ovarian torsion, tubo-ovarian abscess
  – Endometriosis
  – Ruptured graafian follicle

● Urologic
  – Testicular torsion, epididymitis
  – Kidney stones, prostatitis, cystitis, pyleonephritis

● Systemic
  – Diabetic ketoacidosis
  – Henoch-Schönlein purpura
  – Sickle cell crisis
  – Porphyria

● Other
  – Acute mesenteric lymphadenitis
  – No organic pathologic condition
  – Hernias
  – Psoas abscess
  – Rectus sheath hematoma
  – Epiploic appendagitis
  – Pneumonia (basilar)

**Pediatric Considerations**
● Decreased diagnostic accuracy of history and physical exam
● Higher fever; more vomiting and diarrhea

**Pregnancy Considerations**
● Appendicitis is more difficult to diagnose in pregnancy.
● Normal inflammatory response is suppressed.
● Appendix displaced out of pelvis by gravid uterus

**Geriatric Considerations**
Decreased diagnostic accuracy, more likely to be atypical presentation

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
● Leukocytosis: white blood cell (WBC) >10,000/mm³ (70%)
● Polymorphonuclear predominance—“left shift” (>90%)
● Urinalysis: hematuria, pyuria (30%)
● Human chorionic gonadotropin (hCG) (If positive, rule out ectopic pregnancy.)
● C-reactive protein: nonspecific inflammatory marker; when paired with an elevated WBC, increases predictive value for appendicitis
● Drugs may alter lab results: antibiotics, steroids.
● Imaging if the diagnosis is not clear; helps to detect complications (abscess, perforation)
Plain films: minimal utility, nonspecific findings, may visualize fecalith
CT with contrast: sensitivity 91–98%; specificity 95–99%; imaging modality of choice. Consider radiation dose, particularly in young patients.
Ultrasound: alternative in pregnancy, children, and women with suspected gynecologic pathology. Sensitivity and specificity vary skill of the ultrasonographer. Increasing use adult populations, with positive predictive value approaching 100% in some studies (1)[B]. Can rule in appendicitis but cannot reliably exclude the diagnosis. An effective strategy is to start with ultrasound and, if negative, obtain a CT scan if suspicion warrants.
MRI: increasing use in pregnant patients. May help in patients with contrast allergies renal failure. Limitations include cost, availability, and time required to complete study.
Radioisotope-labeled WBC scans: may be used in patients with indeterminate CT scans and suspected appendicitis as an alternative to observation or surgery. Limitations include availability and time required to complete study.

Diagnostic Procedures/Other
Exploratory laparotomy/laparoscopy. Acceptable appendectomy rates vary based on age and gender and may be higher for females of childbearing age than males.

Test Interpretation
- Acute appendiceal inflammation, local vascular congestion, obstruction
- Gangrene, perforation with abscess (15–30%)
- Fecalith

TREATMENT

GENERAL MEASURES
- Surgery (appendectomy) has been the standard of care for acute, uncomplicated appendicitis. There is growing evidence for medical management in select cases—antibiotic therapy, with appendectomy reserved for those who do not respond to treatment (2).
- Delay in surgery for complicated appendicitis is associated with increased complications and cost (3)[A].

MEDICATION
First Line
- Uncomplicated acute appendicitis: perioperative dose of antibiotic: single dose of cefoxitin or ampicillin/sulbactam (Unasyn) or cefazolin plus metronidazole
- Nonoperative antibiotic of choice: ertapenem for 3 days followed by 7 days PO levofloxacin and metronidazole (4)[B]
- Gangrenous or perforating appendicitis
  - Broadened antibiotic coverage for aerobic and anaerobic enteric pathogens
  - Piperacillin and tazobactam (Zosyn) or ticarcillin and clavulanate (Timentin) or a 3rd-generation cephalosporin plus metronidazole are initial options.
  - Adjust dosage and choice of antibiotic based on intraoperative cultures.
  - Continue antibiotics for at least 7 days postoperatively or until patient becomes afebrile with normal WBC count.
Second Line
- Uncomplicated acute appendicitis: clindamycin plus one of the following: ciprofloxacin, levofloxacin, gentamicin, or aztreonam
- In the case of acute appendicitis complicated by abscess formation or phlegmon in pediatric patients, some studies show initial conservative management with antibiotics alone to carry fewer risks and complications than emergent appendectomy.
- Gangrenous or perforated appendicitis: ciprofloxacin or levofloxacin plus metronidazole or monotherapy with a carbapenem (imipenem and cilastatin, meropenem, ertapenem)

ISSUES FOR REFERRAL
All cases of appendicitis require emergent surgical consultation.

SURGERY/OTHER PROCEDURES
- The American College of Surgeons, Society for Surgery of the Alimentary Tract, and others recommend surgery as the treatment of choice.
- Antibiotic treatment might be used as an alternative in specific patients or if surgery is contraindicated.
- Nonoperative management with antibiotics with up to a reported 39% recurrence rate at 5 years for uncomplicated acute appendicitis ([B]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit all patients with appendicitis.
- Fluid resuscitation with normal saline (NS) or lactated Ringer (LR) solution
- Correct fluid and electrolyte deficits.
- Discharge when tolerating oral intake, return of bowel function, afebrile, normal WBC

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Return to work in 1 to 2 weeks is typically following most cases of uncomplicated appendicitis.
- Restrict activity for 4 to 6 weeks after surgery: no heavy lifting (>10 lb) or strenuous physical activity.
- If managed nonoperatively and patient is >40 years, consider colonoscopy to rule out malignancy.

PATIENT EDUCATION
Postoperative warning signs:
- Anorexia, nausea, vomiting
- Abdominal pain, fever, chills
- Signs/symptoms of wound infection

PROGNOSIS
- Generally uncomplicated course in young adults with unruptured appendicitis
- Extremes of age and appendiceal rupture increase morbidity and mortality.
- Morbidity rates
  - Nonperforated appendicitis: 3%
- Perforated appendicitis: 47%

Mortality rates
- Unruptured appendicitis: 0.1%
- Ruptured appendicitis: 3%
- Patients >60 years of age make up 50% of total deaths from appendicitis.
- Older patients with ruptured appendix: 15%

**Pediatric Considerations**
- Rupture earlier
- Rupture rate: 15–60%

**Pregnancy Considerations**
- Rupture rate: 40%
- Fetal mortality rate: 2–8.5%

**Geriatric Considerations**
Rupture rate: 67–90%

**COMPLICATIONS**
- Wound infection, intra-abdominal abscess; lower rate with antibiotic prophylaxis (5)[A], intestinal fistulas
- Intestinal obstruction, paralytic ileus, incisional hernia
- Liver abscess (rare), pyelophlebitis
- Stump appendicitis: recurrence of appendicitis at appendiceal stump after appendectomy; incidence 0.15% (6)[B]

**REFERENCES**

**ADDITIONAL READING**
SEE ALSO
Algorithm: Abdominal Rigidity

CODES

ICD10
- K35.80 Unspecified acute appendicitis
- K35.2 Acute appendicitis with generalized peritonitis
- K35.3 Acute appendicitis with localized peritonitis

CLINICAL PEARLS
- Anorexia with periumbilical pain localizing to RLQ is the classic history for acute appendicitis.
- Diagnosis is more challenging in children, pregnant patients, and the elderly due to varying symptoms and signs.
- In equivocal cases, CT is the diagnostic test of choice. Ultrasound and MRI are alternatives.
- Acute appendicitis is the most common surgical emergency during pregnancy.
APPROACH TO TRAVEL MEDICINE COUNSELING
Melissa Jefferis, MD, FAAFP

BASICS

DESCRIPTION
Pretravel consultations are an important way to assess trip plans, determine potential health hazards, and discuss risks and methods of prevention. These visits also provide an opportunity to immunize against vaccine-preventable diseases, offer medications for prophylaxis and/or self-treatment, and deliver patient education to mitigate risks associated with international travel.

EPIDEMIOLOGY

Incidence
There were 1.33 billion international tourist travel arrivals in 2017 (Centers for Disease Control and Prevention [CDC]). Illness and injury are common during travel.

RISK FACTORS
Risks vary by destination, length of the trip, planned activities, age, and health status of the traveler.

- Traveler details
  - Past medical history (age, gender, medical conditions, allergies, medications)
    - Flying is contraindicated within 3 weeks of a myocardial infarction and within 10 days of a thoracic or abdominal surgery.
    - If preexisting eustachian tube dysfunction, use of a vasoconstricting nasal spray immediately before air travel may lessen the occurrence of otitis or barotrauma (1).
    - See CDC Yellow Book for list of special considerations for travelers with chronic medical illnesses including cardiovascular diseases, pulmonary diseases, diabetes, and severe allergic reactions
  - Special conditions (pregnancy, breastfeeding, disability or handicap, immunocompromised state, older age)
    - Flying is generally discouraged after the 36th week of pregnancy. Many airlines require a provider letter if flying after this time.
  - Immunization history
  - Prior travel experience (previous malaria prophylaxis, experience with altitude, illnesses related to prior travel)

- Trip details
  - Itinerary (countries/specific regions, rural or urban; side trips)
  - Timing (length, season, time until departure)
  - Reason for travel
  - Special activities (disaster relief, medical care, high altitude or climbing, diving, cruise ship, rafting, cycling, extreme sports)

GENERAL PREVENTION

- Routine vaccinations
  - Haemophilus influenzae type b
  - Hepatitis B
- Influenza
- Measles, mumps, rubella—more common in countries without routine childhood immunization, including Europe
- Meningococcal—outbreaks common in sub-Saharan Africa especially during the dry season (December through June). Saudi Arabia requires the quadrivalent vaccine for Hajj pilgrims (2).
- Pneumococcal
- Polio
- Rotavirus—common in developing countries. Does not usually cause travelers’ diarrhea in adults so vaccination is only recommended for children
- Tetanus, diphtheria, pertussis
- Varicella—more common in countries without routine childhood immunization
- Zoster—stress may trigger reactivation.
- Human papillomavirus (HPV)—sexual activity during travel may lead to HPV infection.

● Travel-specific vaccinations (destination dependent)
  - Cholera (not available in the United States)
  - Hepatitis A—often recommended regardless of destination
  - Japanese encephalitis
  - Rabies—if immunoglobulin would be difficult to obtain, consider vaccination to simplify postexposure prophylaxis.
  - Tick-borne encephalitis (not available in United States)
  - Typhoid—highest risk in India, Pakistan, and Bangladesh. Do not give oral vaccine to immunocompromised patients or those who have taken antibiotics in the previous 72 hours (2).
  - Yellow fever—highest risk in sub-Saharan Africa and the Amazon regions of South America. Vaccination is not considered valid until 10 days after administration (2).

● Malaria prophylaxis
  - Based on destination, types of planned activities, and patient preferences. CDC has up-to-date recommendations.
  - Chloroquine-sensitive malaria (2,3)
    o Chloroquine—begin 1 to 2 weeks prior to travel, continue 4 weeks after leaving malaria-endemic area; may increase QTc interval (particularly if given with other QTc-prolonging drugs)
      ■ Adult dose: 300 mg base (500 mg salt) orally once weekly
      ■ Pediatric dose: 5 mg/kg base (8.3 mg/kg salt) orally once weekly (up to 300 mg base per dose)
    o Hydroxychloroquine—begin 1 to 2 weeks prior to travel, continue for 4 weeks after leaving malaria-endemic area; dosed weekly
      ■ Adult dose: 310 mg base (400 mg salt) orally once weekly
      ■ Pediatric dose: 5 mg/kg base (6.5 mg/kg salt) orally once weekly (up to 310 mg base per dose)
  - Chloroquine-resistant malaria (2,3)
    o Atovaquone/proguanil—begin 1 to 2 days before travel and continue for 1 week after leaving malaria-endemic area.
      ■ Adult dose: 250 mg/100 mg atovaquone/proguanil PO daily
      ■ Pediatric dose: Tablets contain 62.5 mg/25 mg atovaquone/proguanil hydrochloride.
- 5 to 8 kg: 1/2 pediatric tablet daily
- 8 to 10 kg: 3/4 pediatric tablet daily
- 10 to 20 kg: 1 pediatric tablet daily
- 20 to 30 kg: 2 pediatric tablets daily
- 30 to 40 kg: 3 pediatric tablets daily
- >40 kg: 1 adult tablet daily

- Doxycycline—begin 1 to 2 days before travel and continue for 4 weeks after leaving malaria-endemic area.
  - Adult dose: 100 mg orally daily
  - Pediatric dose: ≥8 years old 2.2 mg/kg up to adult dose of 100 mg daily

- Mefloquine—begin ≥2 weeks before travel and continue for 4 weeks after leaving malaria-endemic area; has a number of drug interactions. Not recommended for people with cardiac conduction abnormalities (especially ventricular arrhythmias), major psychiatric disorders, or seizures.
  - Adult dose: 228 mg base (250 mg salt) orally once weekly
  - Pediatric dose
    - ≤9 kg: 4.6 mg/kg base (5 mg/kg salt) orally once weekly
    - >9 to 19 kg: 1/4 tablet once weekly
    - >19 to 30 kg: 1/2 tablet once weekly
    - >30 to 45 kg: 3/4 tablet once weekly
    - >45 kg: 1 tablet once weekly

- Protection against mosquitoes and ticks
  - Avoid areas of known outbreaks of communicable disease. Refer to the CDC Travelers’ Health Web site for updates.
  - Avoid peak exposure times and places.
    - Mosquitoes may bite at any time of the day.
    - Peak biting activity for vectors of some diseases (such as dengue, Zika, and chikungunya) is during daylight hours (1).
    - Peak biting activity for vectors of other diseases (such as malaria, West Nile, and Japanese encephalitis) are most active in twilight periods (dawn and dusk) or after dark.
  - Wear appropriate clothing: Minimize exposed skin.
  - Check for ticks.
  - Bed nets
  - Insecticides and repellants—reapply regularly.
    - DEET
    - Picaridin
    - Oil of lemon eucalyptus
    - IR3535
    - 2-Undecanone

- Traveler’s diarrhea
  - Symptoms range from mild abdominal cramping and urgent loose stools to severe abdominal pain, fever, vomiting, and bloody diarrhea.
  - Differs from food poisoning in which preformed toxins are ingested in food. Nausea and vomiting may both be present though usually resolve within 12 hours.
  - Approximately 80–90% bacterial, 5–8% viral, 10% protozoal (1)
  - Most common bacteria is enterotoxigenic Escherichia coli. Common viruses include
norovirus, rotavirus, and astrovirus. Most common protozoa is Giardia (2)

- Length—bacterial causes last 3 to 7 days if untreated. Viral lasts 2 to 3 days. Protozoal can last weeks to months if not treated.
- High-risk areas include Asia, Middle East, Africa, Mexico, and Central and South America (2).
- Intermediate-risk areas include countries in Eastern Europe, South Africa, and some of the Caribbean islands (2).
- Strategies to minimize diarrhea (2)
  - Wash hands or use sanitizer prior to eating.
  - Avoid raw or undercooked meat, fish, or shellfish, salads, uncooked vegetables, unpasteurized fruit juices, or unpasteurized milk or milk products.
  - Avoid unpeeled raw fruit. Peel it yourself if possible.
  - Tap water may be unsafe for drinking, making ice, preparing food, washing dishes, or brushing teeth; use sealed bottled water if possible.
- For high-risk patients—bismuth subsalicylate reduces incidence of travelers’ diarrhea by 50%; 2 oz of liquid or two chewable tablets 4 times per day (not recommended for children <3 years or pregnant women) (2)
- Treatment based on severity of disease (2)
  - Mild—diarrhea is tolerable, not distressing, and does not interfere with activities. Does not require antibiotics.
  - Moderate—diarrhea is distressing and interferes with planned activities. Antibiotics such as fluoroquinolones, azithromycin, or rifaximin. Loperamide can be used as a monotherapy.
  - Severe—in capacitating diarrhea. Azithromycin is preferred agent though fluoroquinolones and rifaximin can also be used.
- Antibiotic options for travelers’ diarrhea treatment
  - Azithromycin—1,000 mg one time dose, if symptoms not resolved in 24 hours then continue daily dosing for 3 days. Alternate dosing is 500 mg daily for 3 days.
  - Ciprofloxacin—750 mg one time dose, if symptoms not resolved in 24 hours then continue daily dosing for 3 days. Alternate dosing is 500 mg BID × 3 days.
  - Rifaximin 200 mg TID × 3 days
- Adjunct medications
  - Loperamide
    - 4 mg initially followed by 2 mg after each loose stool (max 16 mg/day)
    - Pediatric dose
    - Not recommended for children <6 years
    - 6 to 8 years—2 mg initial dose, followed by 1 mg after each loose stool (max 4 mg/day)
    - 9 to 11 years—2 mg after initial dose, followed by 1 mg after each loose stool (max 6 mg/day)
    - 12 years: Refer to adult dosing.
  - Diphenoxylate
    - 5 mg (2 tablets) 3 or 4 times per day until control achieved (max 20 mg/day)
    - Pediatric dose: not recommended for children <2 years; 0.3 to 0.4 mg/kg/day in 4 divided doses
- Altitude illness
More likely at an altitude of 8,000 ft (2,500 m) or higher though can occur at lower altitudes. Children and adults are equally susceptible. Factors that increase risk are elevation at destination, rate of ascent, and exertion (2).

Acute mountain sickness (AMS)—most common. Typically presents with headache starting 2 to 12 hours after arrival. Other symptoms include fatigue, loss of appetite, nausea, and vomiting; usually resolves within 24 to 48 hours of acclimatization (2).

High-altitude cerebral edema (HACE)—severe progression of AMS. Rare though most often associated with HAPE. Lethargy, drowsiness, confusion, ataxia; requires immediate descent (2).

High-altitude pulmonary edema (HAPE)—can occur by itself or with AMS and HACE. Symptoms begin with shortness of breath on exertion and progress to shortness of breath at rest, weakness, and cough. Supplemental oxygen and immediate descent. HACE and HAPE can be fatal though HAPE is more rapidly fatal (2).

Preventive measures
- Ascend gradually—from low altitude to <9,000 feet in 1 day. >9,000 feet, don’t climb >1,600 feet per day. Plan an extra day for acclimatization every 3,300 feet (2).
- In first 48 hours, avoid alcohol and only perform mild exercise.

Preventive medications
- Recommended for those at high risk for AMS (based on rate of ascent or history of HACE or HAPE): Consider for those at moderate risk.
- Acetazolamide—AMS/HACE prevention dose: 125 mg BID (250 mg BID if >100 kg); pediatric dose: 2.5 mg/kg q12h (2)
  - AMS treatment dose: 250 mg BID; pediatric dose: 2.5 mg/kg q12h. Used as an adjunct to dexamethasone.
- Dexamethasone—usually reserved for treatment; prevention dose: 2 mg q6h or 4 mg q12h; should not be used for prophylaxis in pediatric patients (2)
  - AMS treatment dose: 4 mg q6H PO, IV, or IM (2)
  - HACE treatment dose: 8 mg once, then 4 mg q6H PO, IV, or IM. Pediatric dose: 0.15 mg/kg/dose q6H up to 4 mg (2).
- Nifedipine—for prevention and treatment of HAPE; dose: 30 mg SR q12h (2)
- Tadalafil—for prevention of HAPE only; dose: 10 mg BID (2)
- Sildenafil—for HAPE prevention; dose: 50 mg q8H (2)

Jet lag
- Before travel, adjust sleep cycle (and possibly meal times) 1 to 2 hours earlier or later (depending on direction of travel) for several days prior to departure.
- Drink plenty of water to remain hydrated.
- Optimize sunlight exposure to destination.
- Sedative hypnotics (nonbenzodiazepine), such as zolpidem, can be useful.
- If using benzodiazepines, use short-acting agents, such as temazepam.

Motion sickness
- High-risk individuals
  - Children age 2 to 12 years
  - Women, especially when pregnant, menstruating, or on hormones
  - People who get migraines, especially during a migraine
  - Some medications
- Prevention strategies
Avoidance of known triggers
- Strategic positioning (front of car, overwing of aircraft)
- Treatment
  - Dimenhydrinate pediatric dose: 1.0 to 1.5 mg/kg 1 hour before travel and every 6 hours during the trip
  - Diphenhydramine: pediatric dose: 0.5 to 1.0 mg/kg per dose up to 25 mg 1 hour before travel and every 6 hours during the trip
  - Scopolamine—transdermal patch to hairless area behind ear at least 4 hours prior to exposure and every 3 days as needed. Should not be used in children.

Environmental hazards
- Avoid walking barefoot (parasites can enter skin).
- Avoid swimming in freshwater where there is a risk for schistosomiasis or leptospirosis.
- Use sunscreen.
- If scuba diving, avoid flying or altitude exposure >2,000 feet (2).
  - ≥12 hours after surfacing from nondecompression dive
  - ≥18 hours after repetitive dives or multiple days of diving
  - 24 to 28 hours after a dive that required decompression stops

Other information
- Avoid contact with animals because bites and scratches may transmit rabies.
- Discuss risks such as traffic accidents, alcohol misuse, personal assault, robbery, and water safety.
- Check hotels or other sleeping locations for bed bugs on bedding and furniture.
- Consider travel insurance (including coverage for evacuation).
- Hand carry medications and supplies.
- Include medications to manage exacerbations or complications of existing chronic diseases.
- Avoid areas with known outbreaks of communicable disease. Reference the CDC Travelers’ Health Web site before travel.
- The Department of State’s Smart Traveler Enrollment Program provides destination-specific travel alerts.

ADDITIONAL READING

**CODES**

**ICD10**
- Z71.9 Counseling, unspecified
- Z71.89 Other specified counseling

**CLINICAL PEARLS**
- The CDC Travelers’ Health Web site is a useful point-of-care tool for destination-specific travel advice (https://wwwnc.cdc.gov/travel/).
- To allow adequate time for vaccine response and delivery of necessary pretrip medications, patients should seek advice several weeks prior to anticipated travel.
ARTERITIS, TEMPORAL
Karl T. Clebak, MD, FAAFP ▪ Munima Nasir, MD ▪ Chloe S. Courchesne, MD

BASICS

DESCRIPTION
- Technically termed giant cell arteritis (GCA)
- A chronic, generalized, cellular, and humoral immune-mediated vasculitis of large- and medium-sized vessels, predominantly affecting the cranial arteries originating from the aortic arch, although vascular involvement may be widespread. Inflammation of the aorta is observed in 50% of cases.
- Frequent features include fatigue, headaches, jaw claudication, loss of vision, scalp tenderness, polymyalgia rheumatica (PMR), and aortic arch syndrome (decreased or absent peripheral pulses, discrepancies of blood pressure, arterial bruits).
- Considered medical emergency due to risk of permanent vision loss if not treated

EPIDEMIOLOGY
- Most common form of systemic vasculitis affecting persons ≥ 50 years old
- Typically occurs ages 70 to 80 years (80% of cases)
- Women are affected about 2 times as often as men.
- Most common vasculitis in individuals of Northern European descent (Scandinavian countries)
- Rare in Asians and African Americans
- Lower body mass index (BMI) associated with increased risk

Incidence
- Prevalence in individuals >50 years: 1 in 500
- Peaks in patients >70 years old

Prevalence
2 per 1,000 persons

ETIOLOGY AND PATHOPHYSIOLOGY
- The exact etiology of GCA remains unknown, although current theory suggests that advanced age, ethnicity, and specific genetic predisposition lead to a maladaptive response to endothelial injury, intimal hyperplasia, and ultimately vascular stenosis.
- Temporal arteritis (TA) is a chronic, systemic vasculitis primarily affecting the elastic lamina of medium- and large-sized arteries. Histopathology of affected arteries is marked by transmural inflammation of the intima, media, and adventitia, as well as patchy infiltration by lymphocytes, macrophages, and multinucleated giant cells. Mural hyperplasia can result in arterial luminal narrowing, resulting in subsequent distal ischemia.
- Current theory regarding the etiology of TA is that a maladaptive response to endothelial injury leads to an inappropriate activation of T-cell–mediated immunity via immature antigen-presenting cells. The subsequent release of cytokines within the arterial vessel wall can attract macrophages and multinucleated giant cells, which form granulomatous infiltrates and give diseased vessels their characteristic histology. This also leads to an oligoclonal expansion of
T-cells directed against antigens in or near the elastic lamina. Ultimately, this cascade results in vessel wall damage, intimal hyperplasia, and eventual stenotic occlusion.

- In recent years, GCA and PMR have increasingly been considered to be closely related conditions.
- Varicella zoster virus has been proposed as possible immune trigger for GCA; however, this has not been substantiated, and adjunctive treatment with antivirals remains controversial.

**Genetics**
The genes HLA-DRB1–04 has been identified as a risk factor for TA, and polymorphisms of ICAM-1 and PTPN-22 have also been implicated.

**RISK FACTORS**
- Increasing age >70 years is the greatest risk factor.
- Genetic predisposition
- Environmental factors influence susceptibility.
- History of smoking
- Early menopause (<43 years) and lower BMI at menopause in women 50 to 69 years old

**COMMONLY ASSOCIATED CONDITIONS**
Population studies have shown 40–60% of patients diagnosed with GCA also have PMR symptoms, and 16–21% of patients with PMR have GCA.

**DIAGNOSIS**

**HISTORY**
- Most common presenting symptom is headache (2/3 of patients).
- Constitutional symptoms (fever, fatigue, weight loss)
- Any visual disturbances (amaurosis fugax, diplopia)
- Vision loss (20% of patients); unilateral is most common, often proceeds to bilateral if untreated.
- Jaw claudication (presence of symptom significantly increases likelihood of a positive biopsy)
- Scalp tenderness or sensitivity
- Claudication of upper extremities or tongue
- Symptoms of PMR (shoulder and hip girdle pain and stiffness)
- Distal extremity swelling/edema
- Upper respiratory symptoms

**PHYSICAL EXAM**
- Temporal artery abnormalities (beading, prominence, tenderness)
- Typically appear “ill”
- Decreased peripheral pulses in the presence of large vessel diseases
- Funduscopic exam shows pale and edema of the optic disc, scattered cotton wool patches, and small hemorrhages.
- Unlike other forms of vasculitis, GCA rarely involves the skin, kidneys, and lungs.
- Bruits supraclavicular, axillary, supra orbital

**DIFFERENTIAL DIAGNOSIS**
Migraines
Herpes zoster
Other vasculitis (Takayasu arteritis, Wegner, polyarteritis nodosa)
Other rheumatologic condition (rheumatoid arthritis, PMR, mixed connective tissue disease)

DIAGNOSTIC TESTS & INTERPRETATION

American College of Rheumatology 1990 classification criteria are as follows:
- Age >50 years
- New localized headache
- Temporal artery abnormality (tenderness to palpation, decreased or absent pulses)
- Erythrocyte sedimentation rate (ESR) >50 mm/hr
- Abnormal temporal artery biopsy showing vasculitis with predominance of mononuclear cell infiltration or granulomatous inflammation

3 or more of the ACR criteria demonstrate a sensitivity of 94.5% and a specificity of 91.2%

Initial Tests (lab, imaging)
- ESR >50 mm/hr (86% sensitivity), although nonspecific (27%); infrequently, may be normal
- C-reactive protein (CRP) >2.45 mg/dL is a more sensitive marker of inflammation (97% sensitivity) and is associated with increased odds of a positive biopsy result.
- A normal ESR and/or CRP renders the diagnosis of GCA unlikely.
- Acute-phase reactants (fibrinogen, interleukin-6) are frequently elevated but very nonspecific and reserved for diagnostically difficult cases.
- Mild anemia: very nonspecific but may be associated with a lower rate of ischemic complications
- Color Doppler ultrasound (US) of the temporal artery may identify vascular occlusion, stenosis, or edema (“halo sign”); it is low cost and noninvasive but also very operator dependent and does not significantly improve on the clinical exam. It may aid in the diagnosis of larger vessel involvement.
- Atherosclerotic disease with carotid intima-media thickness >0.9 mm may mimic halo sign.
- Magnetic resonance imaging (MRI) and magnetic resonance angiography (MRA) may be beneficial in diagnosis (78% sensitive, 90% specific) if performed within 5 days of steroids.
- Positron emission tomography (PET), like MRI/MRA and color Doppler, may be useful in diagnostically difficult cases to quantify the inflammatory burden and early in the course of disease, as the metabolic changes occur prior to structural vascular damage, but it also lacks studies to support its use.

Follow-Up Tests & Special Considerations
- Development of aortic aneurysms (late and potentially serious complication of GCA) can lead to aortic dissection.
- Due to the risk of irreversible vision loss, treatment with high-dose steroids should be started on strong clinical suspicion of TA, prior to the temporal biopsy being done.

Diagnostic Procedures/Other
- Gold standard diagnostic study: histopathologic examination of the temporal artery biopsy specimen (Do not delay starting medication if suspicion as pathology remains up to 14 days after starting steroids.)
- Overall sensitivity is 87%.
- The temporal artery is chosen because of its accessibility in the systemic disease; alternatively,
facial artery or other cranial arteries may be used.
- Length of biopsy specimen should be at least 2 cm to avoid false-negative results because skip lesions may occur.
- Diagnostic yield of biopsy may be increased if procedure is coupled with imaging (high-resolution MRI or color Doppler US).
- Bilateral temporal artery biopsy should not be performed, unless the initial histopathology is negative and the suspicion for GCA remains high.
- May be negative in up to 42% of patients with GCA, especially in large vessel disease, and a negative biopsy alone should not dictate treatment
- Biopsy results are not affected by prior glucocorticoids, so treatment should not be delayed.

**Test Interpretation**
- Inflammation of the arterial wall, with fragmentation and disruption of the internal elastic lamina
- Multinucleated giant cells are found in <50% of cases and are not specific for the disease.
- TA occurs in three histologic patterns: classic, atypical, and healed.

### TREATMENT

**MEDICATION**

**First Line**

Glucocorticoids:
- The typical dose of prednisone is between 40 and 60 mg/day (or 1 mg/kg/day), and the dose may be titrated up to relieve symptoms. Steroids should not be in the form of alternate day therapy because this is more likely to lead to a relapse of vasculitis (1)[A].
- IV steroids indicated if vision loss has been noted, otherwise PO steroids are equally as effective (1)[C]
- Given risk of irreversible vision loss, immediate steroid therapy should be initiated prior to confirmation by biopsy.
- The initial dose of steroids is continued for 2 to 4 weeks and slowly tapered over 9 to 12 months. Tapering may require ≥2 years (1)[A]. Assess for relapse during taper by monitoring symptoms, ESR, CRP.
- Tocilizumab (an IL-6 receptor antagonist) 162 mg SQ weekly or biweekly in addition to prednisone may be superior to prednisone alone, although it does carry a black box warning regarding increased risk of opportunistic infections (2)[B].
- It has been suggested that low-dose aspirin might be effective for patients with GCA (3)[B].

**Second Line**
- Methotrexate as an adjunct to glucocorticoid therapy may have a modest effect in decreasing the relapse rate of TA (4)[A].
- Cyclophosphamidé have shown some benefit in patients who have not adequately responded to glucocorticoids (5)[A].
- Therapies directed at tumor necrosis factor as adjunct to steroids have not shown significant benefit (1)[B].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Sun avoidance and protection of the head and the face from photodamage may eventually prove to be important preventive measures for TA.

Patient Monitoring
- TA is typically self-limited and lasts several months or years.
- Overall, TA does not seem to decrease longevity. Nevertheless, it may lead to serious complications such as visual loss, which occurs in about 15–20% of patients.
- Another complication of GCA is the development of aortic aneurysms, usually affecting the ascending aorta. Yearly, chest x-rays may be useful to identify this problem (6)[C].
- About 50% of the patients with GCA will eventually develop PMR (stiffness of shoulder and hip girdle).
- Low-dose aspirin should be given as indicated by atherosclerosis guidelines.

DIET
Calcium and vitamin D supplementation should be administered for osteoporosis prevention associated with prolonged corticosteroid therapy.

PATIENT EDUCATION
- Consequences of discontinuing steroids abruptly (adrenal insufficiency, disease relapse)
- Risks of long-term steroid use (infection, hyperglycemia, weight gain, impaired wound healing, osteoporosis, hypertension)
- Possibility of relapse and importance of reporting new headaches and vision changes to provider immediately

PROGNOSIS
- Variable duration of disease, from one year to chronic course.
- Life expectancy is not affected by the disease unless severe aortitis is present.
- Once vision loss has occurred, it is unlikely to be recovered, but treatment resolves the other symptoms and prevents future vision loss and stroke.
- In most patients, glucocorticoid therapy can eventually be discontinued without complications. In patients with chronic disease, however, prednisone may need to be continued for years.
- Disease relapse is possible.

COMPLICATIONS
- Vision loss with delayed diagnosis
- Glucocorticoid-related toxicity

SEE ALSO

- Depression; Fibromyalgia; Headache, Cluster; Headache, Tension; Polymyalgia Rheumatica; Polymyositis/Dermatomyositis

CODES

ICD10

- M31.6 Other giant cell arteritis
- M31.5 Giant cell arteritis with polymyalgia rheumatica

CLINICAL PEARLS

- Due to the risk of irreversible vision loss, treatment with high-dose steroids (prednisone 60 mg/day) should be started immediately in patients suspected of TA.
- Temporal artery biopsy is the gold standard for diagnosis. Temporal artery biopsy is not likely to be affected by a few weeks of treatment.
- Treatment consists of a very slow steroid taper. Bone protection therapy and low-dose aspirin should be considered.
- Normal ESR level = value of age/2 for men and age +10/2 for women
- Patients on corticosteroids should be placed on therapy to minimize osteoporosis, unless there are contraindications.
**ARTHRITIS, JUVENILE IDIOPATHIC**
Donna-Marie McMahon, DO, FAAP ● Kathleen M. Vazzana, DO, MSc

---

**BASICS**

**DESCRIPTION**

- Juvenile idiopathic arthritis (JIA) is the most common chronic pediatric rheumatologic disease.
- JIA is associated with significant disability.
  - Age of onset: <16 years of age
  - Common symptoms: joint swelling, restricted range of motion, warmth, redness, pain
  - ≥6 weeks of symptoms prior to diagnosis
- Seven (International League of Associations for Rheumatology [ILAR]) subtypes determined by clinical characteristics in first 6 months of illness (1):
  - Systemic: 10%; preceded by febrile onset of ≥2 weeks with rash, serositis, hepatosplenomegaly, or lymphadenopathy (1)
  - Polyarticular rheumatoid factor (RF) (+): 2–7%; ≥5 joints involvement (1); large and small joints; RF positive on two tests ≥3 months apart (2)
  - Polyarticular RF (−): 10–30%; ≥5 (large and small) joints involved (1); RF negative (2)
  - Oligoarticular: 30–60%; involvement of 1 to 4 joints; risk for chronic uveitis in antinuclear antibodies (ANA) (+) females (1) and axial skeletal involvement in older boys (2). Types: (i) persistent (40%): knee, ankle, elbow; (ii) extended type (20%): >4 joints after first 6 months
  - Psoriatic arthritis: 5%; arthritis with psoriasis or arthritis with >2 of the following: dactylitis, nail changes (pitting), psoriasis in first-degree relative (1)
  - Enthesitis-related arthritis: 1–11%; arthritis and enthesitis or one of them plus at least two of the following: sacroiliac or lumbosacral pain, Reiter syndrome or acute anterior uveitis in first-degree relative, acute symptomatic anterior uveitis, human leukocyte antigen (HLA)-B27 (+), history of ankylosing spondylitis, sacroiliitis with inflammatory bowel disease, onset of arthritis in male >6 years old (1)[C]
  - Undifferentiated arthritis (11–21%): presents with overlapping symptoms in ≥2 categories above or arthritis that does not fulfill above categories (2)
- Systems affected: musculoskeletal, hematologic, lymphatic, immunologic, dermatologic, ophthalmologic, gastrointestinal
- Synonyms: juvenile chronic arthritis; juvenile arthritis; juvenile rheumatoid arthritis (JRA); Still disease (2)

**EPIDEMIOLOGY**

- Male = female (1); onset: throughout childhood; 54% of cases occur in children 0 to 5 years.
- Polyarticular RF (+): female > male, 3:1 (2); onset: late childhood or adolescence (1)
- Polyarticular RF (−): female > male, 3:1; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)
- Oligoarticular: female > male, 5:1; onset: 2 to 4 years (2)
- Psoriatic: female > male, 1:0.95 (2); onset: early peak, 2 to 3 years; late peak, 10 to 12 years (1)
Enthesitis: female > male; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)

Affected patients have an increased risk of developing cancer, although short-term risk is low.

**Incidence**
2 to 20/100,000 children <16 years in developed nations

**Prevalence**
16 to 150/100,000 children <16 years in developed nations (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Humoral and cellular immunodysregulation. T lymphocytes play a key role.
- Genetic predisposition; IL2RA/CD25 and VTCN1 implicated as genetic loci
- Environmental triggers, possibly infectious
  - Rubella or parvovirus B19 (3)
  - Heat shock proteins (3)
- Immunoglobulin or complement deficiency

**Genetics**
- HLA class I (A, B, C) and II (DR, DP, DQ) alleles
- HLA-A2 = early onset oligoarthritis in females
- HLA class II increases risk of systemic and oligoarticular JIA.
- HLA-B27 increases risk of enthesitis-related arthritis.
- HLA-DR4 is associated with polyarthritis RF (+) (3)[C].

**RISK FACTORS**
Female gender 3:1

**GENERAL PREVENTION**
None identified

**COMMONLY ASSOCIATED CONDITIONS**
Other autoimmune disorders, chronic anterior uveitis (iritidocyclitis), nutritional impairment, growth issues (3)[C]

**DIAGNOSIS**
Clinical criteria: age of onset <16 years and >6 weeks duration of objective arthritis (swelling or restricted range of motion of a joint with heat, pain, or tenderness and no other form of childhood arthritis) in ≥1 joints

**HISTORY**
- Arthralgias, fever, fatigue, malaise, myalgias, weight loss, morning stiffness, rash
- Limp, if lower extremity involvement
- Arthritis for ≥6 weeks

**PHYSICAL EXAM**
- Arthritis: swelling, effusion, loss of musculoskeletal landmarks, limited range of motion, tenderness, pain with motion, warmth
- Rash, rheumatoid nodules (uncommon), lymphadenopathy, hepato- or splenomegaly,
enthesitis, dactylitis (mainly in psoriatic type)

**DIFFERENTIAL DIAGNOSIS**
- Legg-Calvé-Perthes, toxic synovitis, growing pains, Perthes disease
- Septic arthritis, osteomyelitis, viral infection, mycoplasmal infection, Lyme disease
- Reactive arthritis: postinfectious, rheumatic fever, Reiter syndrome
- Inflammatory bowel disease
- Hemoglobinopathies, hemorrhathrosis, rickets
- Leukemia (particularly acute lymphocytic leukemia), bone tumors (osteoid osteoma), neuroblastoma
- Vasculitis, Henoch-Schönlein purpura, Kawasaki disease
- Systemic lupus erythematosus, dermatomyositis, mixed connective tissue disease, sarcoidosis, systemic sclerosis, collagen disorders
- Farber disease
- Accidental or nonaccidental trauma

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Complete blood count (CBC): Leukocyte count is normal or elevated (systemic); lymphopenia, reactive thrombocytosis, anemia; liver function test (LFT; hepatic involvement) and renal function studies (prior to therapy with nephrotoxic drugs)
- Joint-fluid aspiration/analysis to exclude infection
- Erythrocyte sedimentation rate and C-reactive protein typically elevated; C-reactive protein often disproportionately high
- Myeloid-related proteins (MRP 8/14) associated with flares
- ANA-positive patients have increased risk of uveitis; ANA positive in up to 70% with oligoarticular JIA
- RF (+): 2–10% (usually polyarticular); poor prognosis
- HLA-B27 positive: enthesitis-related arthritis
- Diagnostic radiography, magnetic resonance imaging (MRI), ultrasound, and computed tomography (CT); no one modality has superior diagnostic value
- Radiograph of affected joint(s): early radiographic changes: soft tissue swelling, periosteal reaction, juxta-articular demineralization; later changes: joint space loss, articular surface erosions, subchondral cyst formation, sclerosis, joint fusion
- If orthopnea, obtain ECG to rule out pericarditis.
- Radionuclide scans: for infection/malignancy
- CT is best for bony abnormalities. MRI can assess synovial hypertrophy and cartilage degeneration; MRI more sensitive to monitor disease activity and clinical responsiveness to treatment in peripheral joints

**Follow-Up Tests & Special Considerations**
Use pediatric (not adult) controls when interpreting results of dual energy x-ray absorptiometry.

**Diagnostic Procedures/Other**
- **Ultrasound**: Assess for inflammation
- **Synovial biopsy**: if synovial fluid cannot be aspirated or if infection is suspected in spite of negative synovial fluid culture
**Test Interpretation**
Synovial biopsy → synovial cells hyperplasia, hyperemia, infiltration of small lymphocytes, and mononuclear cells

**TREATMENT**

**GENERAL MEASURES**
- Goal is to control active disease, minimize extra-articular manifestations, and achieve clinical remission.
- All patients require regular (every 3 to 4 months for oligoarticular JIA and in ANA-positive patients) ophthalmic exams to uncover asymptomatic eye disease, particularly for the first 3 years following diagnosis.
- Moist heat or electric blanket for morning stiffness
- Splints for contractures
- Aerobic exercise: weight-bearing or aquatic therapy to improve functional capacity

**MEDICATION**

**First Line**
- ≤4 joints
- Nonsteroidal anti-inflammatory drugs (NSAIDs): adequate in ~50%; symptoms often improve within days; full efficacy 2 to 3 months
- Drugs for children include:
  - Ibuprofen: 30 to 50 mg/kg/day, divided QID; max dose 2,400 mg/day
  - Naproxen: 10 to 15 mg/kg/day, divided BID; max dose 1,250 mg/day
  - Tolmetin sodium: 20 mg/kg/day, TID or QID; max dose 30 mg/kg/day
  - Diclofenac: 2 to 3 mg/kg, divided TID; max dose 50 mg TID
  - Indomethacin: 1 to 2 mg/kg/day, divided BID to QID; max dose of 4 mg/kg/day or 200 mg/day
- NSAIDs are contraindicated if known allergy.
- Precautions: may worsen bleeding diatheses; use caution in renal insufficiency and hypovolemic states; take with food.
  - Significant drug interactions: may lower serum levels of anticonvulsants and blunt the effect of loop diuretics; NSAIDs may increase serum methotrexate levels.

**Intra-articular long-acting corticosteroids:** immediately effective; improve synovitis, joint damage, contractures, prevent leg length discrepancy (4)[B]
  - Indication: patients with oligoarthritis who fail a 2-month NSAID trial or with poor prognosis (2)
  - Triamcinolone hexacetonide

**≥5 joints**
- If high disease activity or a failed 1 to 2 months NSAID trial → methotrexate (5)[C]

**Second Line**
- 30–40% of patients require addition of disease-modifying antirheumatic drugs (DMARDs): methotrexate, sulfasalazine, leflunomide, and tumor necrosis factor (TNF) antagonists (etanercept, infliximab, adalimumab); newer biologic therapies, including IL-1 and IL-6 receptor antagonists, are currently under investigation.
Methotrexate: 10 mg/m²/week PO or SC
- Plateau of efficacy reached with 15 mg/m²/week; further increase in dosage is not associated with therapeutic benefit.

Sulfasalazine: oligoarticular and HLA-B27 spondyloarthritis

Etanercept: 0.8 mg/kg (max of 50 mg/dose) given SC q1wk or 0.4 mg/kg SC twice a week (max of 25 mg/dose)

Infliximab: 5 mg/kg q6–8wk

Adalimumab: if weight 15 kg to <30 kg, 20 mg SC q2wk; if weight ≥30 kg, 40 mg SC q2wk

Rituximab: monoclonal antibody; National Health Service (NHS) England guidelines recommend for polyarticular RF+ who have failed two TNF-α inhibitors (4)

Tocilizumab: now included in the NHS England guidelines for RF-pJIA who have failed two TNF-α inhibitors (4)

Anakinra: IL-1 receptor antagonist is being used as monotherapy or in combination with other treatments (6)

Begin treatment with TNF-α inhibitors in children with a history of arthritis in 4 joints and significant active arthritis despite treatment with methotrexate or arthritis in ≥5 joints and any active arthritis following an adequate trial of methotrexate (6)[C]

Begin treatment with anakinra in children with systemic arthritis and active fever whose treatment requires a second medication, in addition to systemic glucocorticoids (6)

Analgesics, including narcotics for pain control

ISSUES FOR REFERRAL
- Pediatric rheumatologist for management of JIA
- Orthopedics as needed for articular complications
- Ophthalmology to evaluate for uveitis
- Physical therapy to maintain range of motion, improve muscle strength, and prevent deformities
- Occupational therapy to maintain and improve appropriate age-related functional activities
- Behavioral health if difficulty coping with disease

SURGERY/OTHER PROCEDURES
- Total hip and/or knee replacement for severe disease
- Soft tissue release if splinting/traction unsuccessful
- Correct limb length or angular deformities.
- Synovectomy is rarely performed.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit if:
  - Patient unable to ambulate
  - Signs/symptoms of pericarditis
  - Persistent fever or diagnostic confusion to facilitate evaluation and workup
  - Need for surgery
- Discharge when fever, swelling, and serositis resolved.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
Determined by medication and disease activity
- NSAIDs: periodic CBC, urinalysis, LFTs, renal function tests
- Aspirin and/or other salicylates: transaminase and salicylate levels weekly for 1 month and then every 3 to 4 months
- Methotrexate: monthly LFTs, CBC, BUN, creatinine

**Diet**
Regular diet. Ensure adequate calcium, iron, protein, and caloric intake.

**Patient Education**
- Psychosocial needs; school issues; behavioral strategies for dealing with pain and noncompliance; available health care resources; support groups

**Prognosis**
- 50–60% of patients will ultimately achieve remission.
- Functional ability depends on adequacy of therapy (disease control, maintaining muscle and joint function).
- Poor prognosis: patients with active disease at 6 months; polyarticular disease; extended pauciarticular disease course; female gender; RF (+); ANA (+); persistent morning stiffness; rapid appearance of erosions; hip involvement

**Complications**
- Blindness, band keratopathy, glaucoma, short stature, micrognathia if temporomandibular joint involvement, debilitating joint disease, disseminated intravascular coagulation, hemolytic anemia
- NSAIDs: peptic ulcer, GI hemorrhage, CNS reactions, renal disease, leukopenia
- DMARDs: bone marrow suppression, hepatitis, renal disease, dermatitis, mouth ulcers, retinal toxicity (antimalarials; rare)
- TNF antagonists: higher risk of infection
- Osteoporosis, avascular necrosis
- Methotrexate: Folate supplementation decreases hepatic/GI symptoms; may reduce stomatitis
- Macrophage activation syndrome: decreased blood cell precursors secondary to histiocyte degradation of marrow

CLINICAL PEARLS
- JIA is the most common form of arthritis in children.
- Consider JIA in any child presenting with a limp.
- High-titer RF correlates with disease severity; prognosis worse if positive RF titers
- DMARDs improve JIA-associated symptoms.
**ARTHITIS, PSORIATIC**

Nikki A. Levin, MD, PhD • Lorena C. Dollani, MD

---

**BASICS**

A chronic, destructive, seronegative arthropathy most common in patients with long-standing psoriasis

**DESCRIPTION**

- **Psoriatic arthritis (PsA)** is a seronegative spondyloarthropathy characterized by inflammatory arthritis and enthesitis.

- Five patterns of arthritis in PsA:
  - Asymmetric oligoarthritis: <5 joints
  - Distal interphalangeal (DIP) joint predominant: osteoarthritis-like, associated with nail psoriasis
  - Symmetric polyarthritis: may be indistinguishable from rheumatoid arthritis (RA)—typically milder
  - Spondyloarthritis: asymmetric and discontinuous, unlike ankylosing spondylitis (AS)
  - Arthritis mutilans: destructive, resorptive arthritis; produces “opera-glass” or “telescoping” digit

- Psoriasis may be limited in extent.
  - Course of arthritis and extent of psoriasis do not correlate.
  - Other extra-articular features, such as iritis, are less common.
  - Damaging joint disease may occur in 40–60%. Characteristic radiologic changes include “pencil-in-cup” deformity and periostitis.

- Rheumatoid factor (RF) and anti–cyclic citrullinated peptide (anti-CCP) antibody are usually negative. HLA-B27 may be positive.

**EPIDEMIOLOGY**

- Peak onset age: 30 to 50 years
- Predominant gender: female = male
- Polyarthritis is more common in women.
- Spondylitis in up to 25%, more common in males
- Psoriasis precedes arthritis in most patients by an average of 12 years. Arthritis preceding psoriasis occurs in up to 15% of patients, usually children. Arthritis and psoriasis may present simultaneously.
- Psoriasis occurs in 2–3% of the U.S. population; 6–42% will develop PsA (1).

**Prevalence**

Prevalence: 1 to 2/1,000 population (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**

- CD4+/CD8+ T cells; tumor necrosis factor α (TNF-α); interleukins 1 (IL-1), 6, 8, and 10; and matrix metalloproteases present in synovial fluid
- Osteoclast precursor cell upregulation
- Unknown. Probably multifactorial: immunologic, genetic, environmental factors
Genetics
- 30–40% concordance in identical twins
- HLA-B27 in 15–50% with PsA (spondylitis pattern) versus 90% in AS
- Other HLA associations in PsA: HLA-B7, HLA-B38, HLA-B39, HLA-Cw6

RISK FACTORS
- Psoriasis
- Family history of PsA

GENERAL PREVENTION
No known prevention strategies; unknown whether early treatment of psoriasis prevents onset of PsA

COMMONLY ASSOCIATED CONDITIONS
Psoriasis

DIAGNOSIS
- A history of inflammatory arthritis, dactylitis, or enthesitis in patients with existing psoriasis helps establish the diagnosis. It can be difficult to differentiate PsA from other inflammatory arthropathies
- Use Classification of PsA (CASPAR) criteria (91% sensitivity; 99% specificity) to screen patients for PsA. Inflammatory articular disease (joint, spine, or enthesal) with ≥3 points from the following five categories:
  - Evidence of current psoriasis, a personal or family history of psoriasis (2 points)
  - Typical psoriatic nail dystrophy, including onycholysis, pitting, and hyperkeratosis (1 point)
  - Negative RF (enzyme-linked immunosorbent assay preferred) (1 point)
  - Current or prior history of dactylitis (1 point)
  - Radiologic evidence of new bone formation (excluding osteophyte formation) on plain radiographs of the hand or foot (1 point)

HISTORY
History and physical exam help establish the diagnosis of PsA.
- (Generally) long-standing history of psoriasis
- Morning stiffness of hands, feet, or low back for ≥30 minutes
- Pain of involved joints
- Swelling or redness of peripheral joints
- Low back or buttock pain
- Ankle or heel pain
- Dactylitis or uniform swelling of an entire digit

PHYSICAL EXAM
- Affected peripheral joints may have overlying erythema, warmth, and swelling.
  - Synovitis
  - Dactylitis
  - Swelling of tendons (e.g., Achilles tendon) and tenderness at insertion sites (e.g., calcaneus)
  - Limited range of motion of axial skeleton
– Pain with stress of the sacroiliac joint

- Well-demarcated pink-to-red erythematous plaques with a white silvery scale; common locations include scalp, ears, trunk, buttocks, gluteal cleft, elbows and forearms, knees and legs, and palms and soles.
- Nails may be dystrophic with pits, oil spots, crumbling, leukonychia, and red lunulae.

DIFFERENTIAL DIAGNOSIS

- Reactive arthritis
- Psoriasis and RA
- Psoriasis and osteoarthritis
- Psoriasis and polyarticular gout
- Psoriasis and AS

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Serum RF (usually negative)
- Anti-CCP (usually negative)
- Antinuclear antibodies (usually negative)
- Acute-phase reactants (ESR and C-reactive protein) may be elevated.
- HLA-B27 is noted in 50–70% with axial disease and <15% with peripheral disease.
- Baseline radiographs of affected joints
- Plain radiographs may aid diagnosis, assess joint damage, disease progression, and response to therapy.
- Juxta-articular new bone formation (periostitis) and marginal joint erosions that progress centrally (“pencil-in-cup” erosions) are characteristic radiographic features.

Follow-Up Tests & Special Considerations

Follow-up radiographs; interval based on severity

Diagnostic Procedures/Other

Diagnosis is typically clinical.

Test Interpretation

Biopsy of skin or synovium is not usually required.

TREATMENT

GENERAL MEASURES

Physical therapy and/or occupational therapy benefit all stages of disease.
- Treatment algorithms for PsA are based on severity of joint symptoms, extent of structural damage, and severity of psoriasis.
- Patients with moderate to severe arthritis should be started on disease-modifying antirheumatic drugs (DMARDs) to reduce or prevent joint damage and preserve joint integrity and function.
- In addition to pharmacotherapy, patients should be educated on lifestyle modifications such as smoking cessation, weight reduction, joint protection, physical activity, exercise, and stress coping mechanisms (2).
MEDICATION

First Line

- Nonsteroidal anti-inflammatory drugs (NSAIDs) to control symptoms of mild disease. Intermittent intra-articular glucocorticoid injections may help.
- There are no systematic trials of NSAIDs for PsA. Dose NSAID to suppress mild inflammation. NSAID selection is based on patient preference and dosing convenience. Sample NSAIDs include ibuprofen 400 to 800 mg PO TID–QID, naproxen 250 to 500 mg PO BID–TID, diclofenac 100 to 150 mg QD, and indomethacin 100 to 150 mg QD.
- Monotherapy is as effective as combination therapy (≥2 drugs from the following: analgesics, NSAIDs, opioids, opioid-like drugs, and neuromodulators [antidepressants, anticonvulsants, and muscle relaxants]) (3)[A].

Second Line

- Recommended DMARDs include sulfasalazine, leflunomide, methotrexate. There is no evidence to support the use of combination DMARD therapy.
- Initial dosing regimens for DMARDs: sulfasalazine (2 to 3 g/day PO divided in BID dosing), leflunomide (loading dose of 100 mg/day PO for 3 days and then 20 mg/day PO), methotrexate (1 test dose of 2.5 to 5.0 mg PO to assess for significant bone marrow suppression and then 15 to 25 mg once weekly), azathioprine (0.5 mg/kg/day, with a max dose of 2.5 mg/kg/day if no signs of cytopenia at lower doses)
- Avoid systemic corticosteroids if possible (may help in short term for severe flares while initiating a biologic agent).
- Consider anti–TNF-α therapy in patients who do not respond to at least one standard DMARD or in patients with poor prognosis, even if they have not failed a standard DMARD (4)[A].
- Dosing regimens for biologics: adalimumab (40 mg SC q2wk), etanercept (50 mg SC weekly), golimumab (50 mg SC monthly), infliximab (5 mg/kg at 0, 2, and 6 weeks, q8wk afterward); certolizumab pegol 200 mg every 2 week; for maintenance dosing or 400 mg every 4 weeks
- Anti–IL-17 agents include:
  - Ixekizumab 80 mg q2wk (5)
  - Secukinumab 150 mg weekly from 0 to 4 weeks and then monthly (5)
  - Brodalumab 210 mg SCx1 weekly from 0 to 2 and then q2wk (6)
- Anti–IL-12/IL-23 agents include:
  - Ustekinumab is currently dosed at 45 or 90 mg (depending on weight) at 0, 4, and 12 weeks and then q12wk thereafter (3).
- PDE4 inhibitors include:
  - Apremilast 30 mg PO BID (5)
- JAK 1 and JAK 3 inhibitors include:
  - Tofacitinib citrate dosed at 5 mg PO BID immediate release or 11 mg once daily extended release (1)
- Selective T-cell costimulation blocker:
  - Abatacept dosed at 125 mg once weekly SC or according to body weight. Following the initial IV infusion (using the weight-based dosing), repeat IV infusion (using the same weight-based dosing) q2wk and q4wk after the initial infusion, and q4wk thereafter (1).
- Above medications are FDA-approved for PsA.
- Do not use anti-TNF agents in the setting of active infection (including tuberculosis and hepatitis B). Do not use anti-TNF agents with concurrent live vaccinations, with New York
Heart Association classes III to IV congestive heart failure, with malignancy, or in patients with a history of demyelinating disease.

- Do not use ustekinumab in patients with active infection, mycobacterial or Salmonella infection, with concurrent live vaccinations, including bacillus Calmette-Guérin vaccination or with history of malignancy.

**Pregnancy Considerations**

- Avoid teratogenic medications (e.g., methotrexate, leflunomide) during pregnancy.
- Adalimumab, etanercept, golimumab, infliximab, ustekinumab, and certolizumab pegol, secukinumab, are currently listed as Category B medications. Apremilast, abatacept, tofacitinib citrate, ixekizumab are listed as pregnancy Category C medication.

**ISSUES FOR REFERRAL**

- Rheumatology
- Dermatology

**SURGERY/OTHER PROCEDURES**

Joint fusion or replacement for advanced destruction

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Epidemiologic data suggest a relationship between psoriasis, metabolic syndrome, myocardial infarction, and stroke. Control of weight, blood pressure, lipids, and glucose is recommended (2).

**PATIENT EDUCATION**

- National Psoriasis Foundation: [http://www.psoriasis.org/i-have-psoriatic-arthritis](http://www.psoriasis.org/i-have-psoriatic-arthritis)
- American College of Rheumatology: [https://www.rheumatology.org](https://www.rheumatology.org)

**PROGNOSIS**

- Course is typically insidious with chronic joint disease and recurring/remitting skin disease.
- Prognosis is more favorable than for RA (except for patients who develop arthritis mutilans).

**COMPLICATIONS**

- Chronicity
- Disability
- Psychosocial impact of psoriasis

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- L40.50 Arthropathic psoriasis, unspecified
- L40.51 Distal interphalangeal psoriatic arthropathy
- L40.53 Psoriatic spondylitis

CLINICAL PEARLS

- One in four patients with psoriasis develops psoriatic arthritis (PsA).
- The severity of psoriasis correlates with the likelihood of developing arthritis, not the severity of arthritis.
- Commonly overlooked locations of psoriasis include scalp, ears, umbilicus, and gluteal cleft.
- Osteoarthritis and polyarticular gout may mimic or coexist with PsA.
- The polyarticular pattern of PsA mimics RA. The presence of both enthesitis and psoriasis helps differentiate PsA from RA.
- Axial skeletal involvement in PsA is asymmetric and discontinuous.
BASICS

DESCRIPTION
- Rheumatoid arthritis (RA) is a chronic autoimmune systemic inflammatory disease (1).
- RA primarily involves synovial inflammation and proliferation leading to destruction of juxta-articular bone and articular cartilage (1).
- Along with articular manifestation, RA also causes various extra-articular manifestations like vasculitis, nodule, or accelerated atherosclerosis.
- Classification:
  - Based on the duration of disease (1)
    - Early: Disease symptoms less than 6 months
    - Established: Disease symptoms more than 6 months or meeting 1987 American College of Rheumatology classification criteria
  - Based on the disease activity (calculated by validated disease activity scale)
    - Remission
    - Low activity
    - Moderate activity
    - High activity

EPIDEMIOLOGY

Incidence
- Annual incidence in North America is 38 (range 31 to 45) cases per 100,000.
- Incidence rates around the world
- Lifetime risk in U.S. males 1.7% females 3.6.

Prevalence
- RA is one of the most commonly present inflammatory arthritis and is prevalent in 0.5% to 1% of the general population worldwide.
- More prevalent in females (female: male, 2:1 to 3:1)

ETIOLOGY AND PATHOPHYSIOLOGY

The cause of RA remains uncertain.
- Often precipitated by some sort of stress or insult (e.g., infection, smoking, trauma)

Genetics
- More than 100 genes have been associated with an increased risk of RA.
- Allelic variant HLA-DRB\textsubscript{1} has been linked to RA associated with antibodies to citrullinated protein epitopes.
- Antibodies to citrullinated protein epitopes found in more than 70% of patients of RA
- Evidence of altered immunity can be present years before the onset of clinical arthritis.
- Cytokine networks involving tumor necrosis factor (TNF), interleukin-6, and many other factors participate in disease progression and can be targeted by therapeutic agents.
RISK FACTORS
- Female gender
- Occurs in females at a younger age (5th to 6th decade) than male (7th to 8th decade)
- Family history
- Some Native American tribes
- Smoking
- Obesity
- Exposure to silica

COMMONLY ASSOCIATED CONDITIONS
Accelerated atherosclerosis, pericarditis, amyloidosis, Felty syndrome (RA, splenomegaly, neutropenia), interstitial lung disease, pulmonary nodules, rheumatoid nodules, vasculitis, lymphomas, carpal tunnel syndrome

DIAGNOSIS

HISTORY
- Early complaints include difficulty using hands and foot pain with weight-bearing.
- Arthritis is typically insidious in onset, gradually progressing and symmetrically involving small joints.
- Morning stiffness lasting more than 1 hour. The pain improves with activity.
- Systemic symptoms like joint stiffness, low-grade fever, and possible weight loss
- Symptoms of carpal tunnel syndrome from synovial thickening
- RA involving the cervical spine can lead to atlantoaxial (C1–C2) subluxation or subaxial subluxation.
- RA symptoms like eye pain, redness, decreased vision, dyspnea, or skin changes.

PHYSICAL EXAM
- Articular
  - Commonly involved joints are metacarpophalangeal (MCP), proximal interphalangeal (PIP), metatarsophalangeal (MTP), and spare distal interphalangeal (DIP) joints
  - Swelling and tenderness of involved joints
  - Ulnar deviation, hyperflexion of the PIP joints with boutonnière deformity, MCP joint subluxation (late in disease), and radial deviation at wrist
  - Palmar erythema, subcutaneous nodules in the extensor surface, olecranon bursa effusion, and decreased range of motion of joints
- Extra-articular
  - Eyes: Keratitis, keratoconjunctivitis, episcleritis, scleritis
  - Lungs: rales from interstitial lung disease or pneumonitis, decrease breath sound from pericardial effusion or pleuritis
  - Cardiac disease: pericardial friction rub from pericarditis, symptoms of congestive heart failure from myocarditis, or murmur from mitral regurgitation
  - Skin: rheumatoid nodules are firm, nontender nodules measuring 2 to 5 cm
  - Vasculitis: splinter hemorrhage, palpable purpura, skin ulceration, and nail fold infarcts
  - Nervous system: nerve entrapment syndromes (sensory and/or motor deficit from synovium thickening) or vasculitis neuropathy (mononeuritis multiplex with asymmetric
sensory and motor finding in at least 2 separate nerve area)

DIFFERENTIAL DIAGNOSIS

- Systemic Lupus erythematosus (SLE), osteoarthritis, Sjögren syndrome, viral disease (hepatitis B, hepatitis C, HIV, parvovirus), tophaceous gout, calcium pyrophosphate dihydrate deposition (CPPD), arthropathy (pseudo RA presentation), polymyalgia rheumatica (PMR), remitting seronegative symmetric synovitis, postinfectious reactive arthritis, Lyme arthritis

- **Differential diagnosis of Rheumatoid nodule**
  - Rheumatic fever, granuloma annulare, xanthomatosis, gouty tophi, multicentric reticulohistiocytosis, and SLE

DIAGNOSTIC TESTS & INTERPRETATION

- **Acute phase reactant**: elevated erythrocyte sedimentation rate (ESR), elevated C-reactive protein (CRP)
- **Serology**: Rheumatoid factor and anticyclic citrullinated peptide (anti-CCP) antibodies
  - Anti-CCP antibodies are present in 60–70% patient with RA but are 90–98% specific for RA. They are often present years before clinical arthritis. It correlates with erosive disease.
  - Rheumatoid factor is positive in 50% of patients at the time of diagnosis and an additional 20–35% become positive in 6 months.
  - RA has many other autoantibodies but are not very specific. It also includes antinuclear antibody (ANA), approximately 30% of patients with RA, and antineutrophil cytoplasmic antibodies (ANCA), approximately 30% of patients with RA.
- **Imaging**: X-ray to follow the progression and identify destruction of disease. MRI of hands and wrists (erosions, pannus, synovitis); ultrasound can assess synovial thickening/erosions.
- Increased ferritin and hemosiderin
- **Diagnostic criteria**
  - Clinical synovitis in at least one joint with no other explanation for the synovitis and at least 6 out of possible 10 score using 2010 American College of Rheumatology/European League Against Rheumatism Classification criteria (1).
  - **Target Population**: those with at least one joint with clinical synovitis that cannot be explained by another condition.
  - **Score of ≥6 to classify as RA**
    - Joint involvement
      - 1 large joint (0 points)
      - 2–10 large joints (1)
      - 1–3 small joints (2)
      - 4–10 small joints (3)
      - >10 joints (5)
    - **Serology**
      - Negative RF or Low Positive Anti-CCP antibodies (0)
      - Low positive RF or Low Positive Anti-CCP antibodies (2)
      - High Positive RF or High Positive Anti-CCP antibodies (3)
    - **Acute Phase Reactants**
      - Normal CRP or ESR (0)
      - Abnormal CRP or ESR (1)
    - **Duration of Symptoms**
      - <6 weeks (0)
      - ≥6 weeks (1)
Diagnostic Procedures/Other
- Joint aspiration (if needed) to exclude crystal arthropathy and septic arthritis
- Synovial fluid analysis:
  - Gram stain, cell count, culture, crystal analysis, and overall appearance
  - Yellowish-white, turbid, poor viscosity in RA
  - White blood cell increased (3,500 to 50,000 cells/mm)
  - Protein: ~4.2 g/dL (42 g/L)
  - Serum-synovial glucose difference >30 mg/dL (>1.67 mmol/L)

TREATMENT

GENERAL MEASURES
- Reduce disease activity with the aim to induce remission/decrease disease activity, decrease joint destruction, prevent disability.
- If remission cannot be attained, aim of treatment is keep disease activity as low as possible to improve the quality of life.
- RA activity should be measured in initial encounter and all follow-up visits.
- The validated scoring system used to measure RA
  - Disease Activity Score in 28 joints (DAS28)
  - Simplified Disease Activity Index (SADI)
  - Clinical Disease Activity Index (CDAI)
  - Rheumatoid Arthritis Disease Activity Index (RADAI)
  - Patient Activity Scale (PAS or PASII)
  - Routine Assessment Patient Index Data (RAPID)

MEDICATION
- Available Disease-Modifying Antirheumatic drug
  - Traditional: Azathioprine, cyclosporine, glucocorticoids, gold, intramuscular and oral, hydroxychloroquine, leflunomide, methotrexate (MTX), minocycline, penicillamine, sulfasalazine, tofacitinib
  - Biologic agent: abatacept, adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab, tocilizumab
- Before starting medication
  - Baseline complete blood count (CBC), hepatic function test and basic metabolic panel
    - Screening for hepatitis B and hepatitis C infection
    - Tuberculin skin test (TST) or interferon gamma release assay (IGRA) before biologics.
    - IGRA preferred if patient had received Bacillus Calmette-Guérin vaccine in past
    - If screening test is positive get chest radiograph.
    - If initial screening is negative, no need for repeat.
- Vaccine recommendations
  - Routine immunization with killed and inactivated vaccine in all eligible patients indicated by Centers for Disease Control and Prevention.
  - Administer varicella-zoster to patients age ≥50 years before initiating therapy with biologics or tofacitinib.
- Early disease
  - Treatment recommendations in disease course less than 6 months and symptomatic patients
o Strong recommendations (2)
  ■ Regardless of disease activity level, use a treat-to-target strategy rather
  ■ If the disease activity is low, in patients who have never taken a DMARD, use
    traditional DMARD monotherapy (MTX preferred) over double or triple therapy
  ■ If the disease activity remains moderate or high despite traditional DMARD
    monotherapy (with or without glucocorticoids), use combination traditional DMARDs
    or THF inhibitor or non-TNF biologic rather that continuing traditional DMARD
    monotherapy.

o Conditional recommendation
  ■ If the disease activity is moderate or high, in patient who have never taken a DMARD,
    use traditional DMARD monotherapy over double or triple therapy.
  ■ If disease activity remains moderate or high despite traditional DMARDs use a TNF
    inhibitor monotherapy or a TNF inhibitor + MTX over tofacitinib monotherapy
  ■ If disease activity remains moderate or high despite traditional DMARD or biologic
    therapies, add low-dose glucocorticoids
  ■ If disease flares, short-term glucocorticoids at lowest dose for shortest duration

• Established disease
  – Strong recommendations
    o Regardless of disease activity, use a treat-to-target strategy rather than non targeted
      approach
    o If the disease activity is low, in patients who have never taken a DMARD, use traditional
      DMARD monotherapy (MTX preferred) over TNF inhibitors
    o If the disease activity remains moderate or high despite traditional DMARD monotherapy,
      use combination traditional DMARDs or add THF inhibitor or non-TNF biologic or
      tofacitinib (all choices with or without MTX) rather that continuing traditional DMARD
      monotherapy.
    o If disease activity is low continue DMARD therapy, TNF inhibitor, non-TNF biologics, or
      tofacitinib rather than discontinuing respective medications
    o If the patient’s disease is in remission, do not discontinue all RA therapies.
  – Conditional recommendation
    o If the disease activity is moderate or high, in patients who have never taken a DMARD, use traditional
      DMARD monotherapy (MTX preferred) over tofacitinib or combination
      DMARD therapy.
    o If the disease activity remains moderate or high despite use of single TNF inhibitor, use a
      non-TNF biologic with or without MXT over another TNF inhibitor or tofacitinib.
    o If the disease activity remains moderate or high despite use of single non-TNF biologics
      use another non-TNF biologic with or without MXT over tofacitinib with or without
      MTX
    o If disease activity remains moderate or high despite use of multiple (2+) sequential TNF
      inhibitor therapies first use a non-TNF biologics with or without MTX over another TNF
      inhibitor or tofacitinib (with or without methotrexate).
    o If disease activity still remains moderate to high despite the use of multiple TNF inhibitor
      therapies and non-TNF biologics cannot be started, use tofacitinib with or without
      methotrexate over another TNF inhibitor with or without methotrexate.
    o If disease activity remains moderate or high despite use of at least one TNF inhibitor and
      at least one non-TNF biologics:
First use another non-TNF biologic, with or without methotrexate, over tofacitinib.

- If disease activity remains moderate to high, use tofacitinib, with or without methotrexate, over another TNF inhibitor.
  - If disease activity remains moderate or high, use a traditional DMARD, TNF inhibitor, or non-TNF biologic therapy; add short-term, low-dose glucocorticoid therapy.
  - If disease flares in patient on traditional DMARD, TNF inhibitor, or non-TNF biologics therapy, add a short-term glucocorticoid at the lowest possible dose and for the shortest possible duration.
  - If the patient is at remission, taper medication off.

- RA in high risk patients
- Congestive heart failure
  - Use combination traditional DMARDs or non-TNF biologic or tofacitinib over TNF inhibitors.
  - If patient is on TNF inhibitor therapy and has CHF worsening: use combination traditional DMARDs or non-TNF biologics or tofacitinib.

- Hepatitis B
  - In active hepatitis B infection and receiving/received effective antiviral treatment, recommendation is same as the patient without this condition.

- Hepatitis C
  - In patient with hepatitis C infection and receiving/received effective antiviral treatment, recommendation is same as the patient without this condition.
  - In patients with hepatitis C infection and not receiving or requiring effective antiviral treatment, use DMARDs over TNF inhibitors.

- Pregnancy
  - Use contraceptives while on DMARDs
  - Methotrexate, leflunomide, cyclophosphamide, and cyclosporin are teratogenic, whereas sulfasalazine and hydroxychloroquine are safe to use during pregnancy and breastfeeding.

- Malignancy
  - Use DMARDs over biologics/tofacitinib in melanoma and non melanoma.
  - In previously treated lymphoproliferative disorder use rituximab over TNF inhibitor.
  - In previously treated lymphoproliferative disorder, use combination DMARD or abatacept or tocilizumab over TNF inhibitor.
  - For solid organ malignancy, treatment is same as without this condition.

- Serious infection
  - In previous serious infection, use combination DMARDs or abatacept over TNF inhibitor.

**ISSUES FOR REFERRAL**

- Refer to Rheumatology and Physical Therapy
- Patients on hydroxychloroquine annual eye exam.

**ADDITIONAL THERAPIES**

- Nutrition and regular physical activity
- Counseling; stress reduction
- Additional analgesics like nonsteroidal anti-inflammatory drug or capsaicin cream

**SURGERY/OTHER PROCEDURES**

- Synovectomy
• Tenosynovectomy
• Tendon alignment
• Reconstructive surgery or arthroplasty
• Arthrodesis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Laboratory monitoring for DMARDs (2)
• Follow CBC, liver transaminases, serum creatinine
• More frequent follow-up is required within first 3 months at initiation of medication or after increase in the dose.

**Patient Monitoring**

DAS28 questionnaire monitor activity; Health Assessment Questionnaire (HAQ) helps evaluate functional status.

**PROGNOSIS**

• Factors related to poor outcome are:
  – Autoantibody (rheumatoid factor and anti-citrullinated protein antibody) positivity
  – Indicative of greater disease activity at baseline
  – Extra-articular disease
• Longer disease duration
  – Diagnostic and treatment delays
  – HLA-DRB1 shared epitope status
  – Cigarette smoking and heavy alcohol use
  – Occupational factors and socioeconomic status
  – Erosive disease
  – Comorbid illnesses, including depression, post-traumatic stress disorder, and others

**REFERENCES**

**CODES**

**ICD10**

• M06.9 Rheumatoid arthritis, unspecified
• M05.60 Rheu arthritis of unsp site w involv of organs and systems
• M05.30 Rheumatoid heart disease w rheumatoid arthritis of unsp site
CLINICAL PEARLS

- Early treatment with DMARDs is essential.
- Methotrexate is the first-line treatment for active disease and glucocorticoids are used for flares if patients are already on DMARD therapy.
BASICS

DESCRIPTION
- Infection due to bacterial invasion of the joint space
- Systems affected: musculoskeletal
- Synonyms: suppurative arthritis; infectious arthritis; pyarthrosis; pyogenic arthritis; bacterial arthritis

EPIDEMIOLOGY

Gender differences:
- Gonococcal: female > male
- Nongonococcal: male > female

Incidence
- May occur at any age; incidence is higher in very young and in the elderly.
- ~20,000 cases/year in U.S. (~8 cases per 100,000 person-years).
- Disseminated gonococcal infection is ~3/100,000 person-years

Prevalence
- 27% of patients presenting with monoarticular arthritis have nongonococcal septic arthritis (1).
- With increasing prevalence of prosthetic joints, infected hardware is now most common form of septic arthritis (ranging from ~2–10% of all joint recipients)

ETIOLOGY AND PATHOPHYSIOLOGY

- Multiple pathogens
- Nongonococcal:
  - Staphylococcus aureus (most common in adults)
    - Methicillin-resistant S. aureus risk increased in elderly, intravenous drug users (IVDU), postsurgical
  - Streptococcus spp. (second most common in adults)
  - Gram-negative rods (GNR): IVDU, trauma, extremes of age, immunosuppressed
- Neisseria gonorrhoeae (most common in young, sexually active adults)
- Other: rickettsial (e.g., Lyme), fungal, mycobacterial
- Risk by specific age (2):
  - <1 month: S. aureus, group B streptococcus (GBS), GNR
  - 1 month to 4 years: S. aureus, Streptococcus pneumoniae, Neisseria meningitidis
  - 16 to 40 years: N. meningitidis, S. aureus
  - >40 years: S. aureus
- Patients with native joint infection are at increased risk for infection of prosthesis (of same joint should it require replacement)
- Specific high-risk groups:
  - Rheumatoid arthritis (RA): S. aureus
  - IVDU: S. aureus, GNR, opportunistic pathogens
– Neonates: GBS
– Immunosuppressed: gram-negative bacilli, fungi
– Trauma patients with open injuries: mixed flora

Pathogenesis:
– Hematogenous spread (most common)
– Direct inoculation by microorganisms secondary to trauma or iatrogenesis (e.g., joint surgery)
– Adjacent spread (e.g., osteomyelitis)

Pathophysiology:
– Microorganisms initially enter through synovial membrane and spread to the synovial fluid.
– Resulting inflammatory response releases cytokines and destructive proteases leading to systemic symptoms and joint damage.

RISK FACTORS
– Age >80 years
– Low socioeconomic status, alcoholism
– Cellulitis and skin ulcers
– Violation of joint capsule
  – Prior orthopedic surgery
  – Intra-articular steroid injection
  – Trauma
– History of previous joint disease
  – Inflammatory arthritis (RA: 10-fold increased risk)
  – Osteoarthritis
  – Crystal arthritides
– Systemic illness
  – Diabetes mellitus, liver disease, HIV, malignancy, end-stage renal disease/hemodialysis, immunosuppression, sickle cell anemia
– Risks for hematogenous spread
  – IVDU, severe sepsis/systemic infection

GENERAL PREVENTION
– Prompt treatment of skin and soft tissue infections.
– Control risk factors.
– Immunization (S. pneumoniae, N. meningitidis)

COMMONLY ASSOCIATED CONDITIONS
Pre-existing joint conditions, previous joint trauma or surgery, prosthetic joint

DIAGNOSIS

HISTORY
– Typically presents with a combination of joint pain, swelling, warmth, and decreased range of motion.
– Nongonococcal arthritis: mostly monoarticular (80%)
  – Typically large joints (knee in 50% of cases); followed by hip (20%); shoulder (8%); ankle (7%).
- Most patients report fever.
- IV drug users may develop infection in axial joints (e.g., sternoclavicular joint).
- Prosthetic joints may show minimal findings and present with draining sinus over the joint.
- Patients on chronic immunosuppressive drugs and those receiving steroid joint injections may have atypical presentations (no fever or joint pain).

- Pediatric considerations
  - Infants may refuse to move limb (can be mistaken as neurologic problem).
  - Hip pain may be referred to knee and/or thigh.

- Gonococcal arthritis
  - Bacteremic phase: migratory polyarthritis, tenosynovitis, high fever, chills, pustules (dermatitis–arthritis syndrome)
  - Localized phase: monoarticular, low-grade fever

**PHYSICAL EXAM**
- Physical exam has poor sensitivity and specificity for septic arthritis. Common findings include:
  - Fever
  - Limited range of motion
  - Joint effusion and tenderness
  - Erythema and warmth over affected joint
  - Pain with passive range of motion
- Hip and shoulder involvement may reveal severe pain with range of motion and less obvious swelling.
- Infants with septic hip arthritis maintain the joint in flexion external rotation.
- Purpura associated with disseminated gonococcal infection

**DIFFERENTIAL DIAGNOSIS**
- Crystal arthritis: gout, pseudogout, calcium oxalate, cholesterol
- Infectious arthritis: fungi, spirochetes, rheumatic fever, HIV, viral
- Inflammatory arthritis: rheumatoid arthritis, spondyloarthropathy, systemic lupus erythematosus, sarcoidosis
- Osteoarthritis
- Trauma: meniscal tear, fracture, hemarthrosis
- Other: bursitis, cellulitis, tendinitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Synovial fluid analysis is the gold standard:
  - Obtain prior to antibiotic therapy when possible.
  - Include Gram stain, culture, cell count/differential, and crystal analysis.
  - Use blood culture bottles to increase yield.
  - Gram stain (positive in 50%); culture (positive in 50–70%)
  - >50,000 white blood cells (WBCs)/high-power field (HPF) with >90% polymorphonuclear leukocytes is suggestive; synovial WBC (sWBC) count alone is insufficient to rule in or rule out septic arthritis (2).
  - Crystals (e.g., urate or calcium pyrophosphate) do not exclude concurrent infectious arthritis.
Prosthetic joint: WBC count is unreliable; a lower number of sWBCs may indicate infection.

Serum tests:
- WBC count alone is neither sensitive nor specific.
  - ESR >15 mm/hr has sensitivity up to 94% but poor specificity (3)[B].
  - C-reactive protein (CRP) >20 mg/L has sensitivity of 92% (3)[B].
  - Synovial lactate is a potential biomarker (4)[A].
- Blood cultures are positive in 50% of cases.

Other tests:
- Disseminated gonococcus: culture blood, cervix, urine, urethra, pharynx in addition to joint fluid
- Suspected Lyme arthritis: PCR and serum titers for Borrelia IgM and IgG—indicate exposure

Pediatrics: No single lab test distinguishes septic arthritis from transient synovitis.
- The combination of fever, non–weight-bearing, and elevated ESR and CRP is suspicious; obtain synovial fluid.

Imaging helps to identify effusion but does not differentiate septic from other forms of arthritis.
- Plain films:
  - Nondiagnostic for septic arthritis; useful for trauma, soft tissue swelling, osteoarthritis, or osteopenia
  - May show nonspecific inflammatory arthritic changes (i.e., erosions, joint destruction, or joint space loss)
- Ultrasound:
  - Guides arthrocentesis
  - Recommended for aspiration of the hip
- MRI:
  - Highly sensitive for effusion; may help distinguish between transient synovitis and septic arthritis in children
- Other imaging techniques:
  - CT is not routinely indicated.
  - Bone scans are not performed unless there is suspicion for osteomyelitis.

Diagnostic Procedures/Other
Arthrocentesis in all suspected cases (prior to starting antibiotics). Avoid contaminated tissue (e.g., overlying cellulitis) when performing arthrocentesis.

Test Interpretation
Synovial biopsy shows polymorphonuclear leukocytes and (possibly) the causative organism.

TREATMENT

GENERAL MEASURES
- Admit for parenteral antibiotics and monitoring. Begin antibiotics immediately after arthrocentesis.
- Drainage of purulent material is required if:
- Pediatric: Surgical drainage and irrigation is recommended if hip is involved due to high risk of avascular necrosis.
- Prosthetic joint: antibiotics and consult with orthopedics for consideration of revision arthroplasty, resection arthroplasty, or débridement
- Antibiotic therapy for total of 4 to 6 weeks in most cases. Native joint infections require at least 2 weeks; prosthetic joint infections longer. Each case should be evaluated individually and contextually.
  - Exception: gonococcal arthritis (2 to 3 weeks)
- Intra-articular antibiotics are not recommended.

MEDICATION

First Line
- Initial antibiotic choice is guided by Gram stain or the most likely organism based on age, clinical history, and risk factors.
- Nongonococcal (5)[C]:
  - Gram-positive cocci:
    - Vancomycin 15 to 20 mg/kg 2 to 3 times daily or linezolid 600 mg twice daily
  - Gram-negative bacilli:
    - Cefepime 2 g twice daily or ceftriaxone 2 g daily or ceftazidime 2 g 3 times daily or cefotaxime 2 g 3 times daily
    - For cephalosporin allergy: Consider treatment with ciprofloxacin 400 mg 3 times daily.
  - Negative Gram stain:
    - Vancomycin 15 to 20 mg/kg 2 to 3 times daily plus 3rd-generation cephalosporin until cultures and susceptibilities return
  - Duration of therapy: typically 2 weeks of IV and an additional 2 to 4 weeks PO while monitoring therapeutic response
- Gonococcal:
  - Ceftriaxone 1 g IV/IM daily for 7 to 14 days (and at least 24 to 48 hours after symptoms resolve)
  - May require concurrent drainage of affected joint
  - Concomitant treatment for Chlamydia (doxycycline 100 mg twice daily or azithromycin 1 g daily)
- Other considerations:
  - Narrow antibiotic therapy based on culture results.
  - Consider Salmonella in pediatric patients with a history of sickle cell disease: 3rd-generation cephalosporin helpful in this instance.
  - Lyme arthritis: doxycycline 100 mg PO twice daily or amoxicillin 500 mg PO 3 times daily for 28 days if no neurologic involvement, otherwise ceftriaxone 2 g IV daily

ISSUES FOR REFERRAL
- Infectious disease and orthopedic consultations.
- Consult ID specialist for IVDU and immunosuppression; prosthetic joint infection best managed with orthopedic consultation.

SURGERY/OTHER PROCEDURES
- Consider drainage in all cases—particularly shoulder, hip, and prosthetic joints.
- Other treatment options include repeat needle aspiration, arthroscopy, or arthrotomy.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Mean duration of hospitalization is 12 days

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Can monitor synovial fluid to verify decreasing WBC and sterile fluid after initial treatment
- If no improvement within 24 hours, reevaluate and consider arthroscopy.
- Follow up at 1 week and 1 month after stopping antibiotics to exclude relapse.

PROGNOSIS
- Early treatment improves functional outcome.
- Delayed recognition/treatment is associated with higher morbidity and mortality.
- Elderly, concurrent RA, S. aureus infections, and infection of hip and shoulder also increase risk of poor outcome.

COMPLICATIONS
- Mortality estimated at 11% (1)
- Limited joint range of motion, ankylosis
- Secondary osteoarthritis
- Flail, fused, or dislocated joint
- Sepsis, septic necrosis
- Sinus formation
- Osteomyelitis, postinfectious synovitis
- Limb length discrepancy (in children)

REFERENCES

ADDITIONAL READING
CODES

ICD10
- M00.079 Staphylococcal arthritis, unspecified ankle and foot
- M00.829 Arthritis due to other bacteria, unspecified elbow
- M00.011 Staphylococcal arthritis, right shoulder

CLINICAL PEARLS
- Arthrocentesis and synovial fluid analysis are mandatory in cases of suspected septic arthritis.
- Gram stain has variable sensitivity in septic arthritis. sWBC count is generally >50,000/HPF but is unreliable as a sole diagnostic feature.
- Early IV antibiotics and (if necessary) drainage of infected joints are critical to successful management.
- Crystalline disease may coexist with septic arthritis.
- Initial antibiotic therapy is guided by arthrocentesis results (Gram stain), age, and patient-specific risk factors.
ARTHROPOD BITES AND STINGS
James E. Powers, DO, FACEP, FAAEM

BASICS
DESCRIPTION

- Arthropods are the largest division of the animal kingdom. Two classes, insects and arachnids, have the greatest impact on human health.
- Arthropods affect humans by inoculating poison, microorganisms, or irritative substances through a bite or sting; by invading tissue, or by contact allergy to their skin, hairs, or secretions.
- Transmission of infectious microorganisms during feeding is of the greatest concern.
- Sequelae of bites, stings, or contact include:
  - Local redness with itch, pain, and swelling: common, usually immediate and transient
  - Large local reactions that increase over 24 to 48 hours
  - Systemic reactions with anaphylaxis, neurotoxicity, organ damage, or other systemic toxin effects
  - Tissue necrosis or secondary infection
  - Infectious disease transmission: Presentation may be delayed weeks to years.

EPIDEMIOLOGY
Incidence
28,087 cases of arthropod exposures were reported in 2015. This is a small fraction of arthropod encounters.

Prevalence
Widespread, with regional and seasonal variations

ETIOLOGY AND PATHOPHYSIOLOGY

- Arthropods: four medically important classes
  - Insects: Hymenoptera (bees, wasps, hornets, fire ants), mosquitoes, bed bugs, flies, lice, fleas, beetles, caterpillars, and moths
  - Arachnids: spiders, scorpions, mites, and ticks
  - Chilopods: centipedes
  - Diplopods: millipedes
- Four general categories of pathophysiologic effects: toxic, allergic, infectious, and traumatic
  - Toxic effects of venom: local (tissue inflammation or destruction) versus systemic (neurotoxic or organ damage)
  - Allergic: Antigens in saliva or venom may cause local inflammation. Exaggerated immune responses may result in anaphylaxis or serum sickness.
  - Trauma: Mechanical injury from biting or stinging causes pain, swelling, and portal of entry for bacteria and secondary infection. Retention of arthropod parts can cause a granulomatous reaction.
  - Infection: Arthropods transmit bacterial, viral, and protozoal diseases.

Genetics
Family history of atopy may be a factor in the development of more severe allergic reactions.

**RISK FACTORS**
- Previous sensitization
- Although most arthropod contact is inadvertent, certain activities, occupations, and travel exposures increase risk.
- Greater risk for adverse outcome in young, elderly, immunocompromised, and those with chronic or poorly controlled cardiac or respiratory disease
- Increased risk of anaphylaxis in patients with mastocytosis

**GENERAL PREVENTION**
- Avoid common arthropod habitats.
- Insect repellents (not effective for bees, spiders, scorpions, caterpillars, bed bugs, fleas, ants)
  - N,N-diethyl-meta-toluamide (DEET)
    - Most effective broad-spectrum repellent against biting arthropods (1,2)[A]
    - Formulations with higher concentrations (20–50%) are first-line choice in areas of endemic arthropod-borne diseases (2)[A].
    - Concentrations >30% have longer duration of action.
    - Safe for children >6 months of age and pregnant and lactating women (2)[B]
  - Icaridin (formerly known as picaridin)
    - 20% spray comparable to 20% DEET for mosquito protection (2)[A]
  - P-menthane-3,8-diol (PMD; lemon eucalyptus extract)
    - 30% concentrations give 4 to 5 hours of protection against mosquitoes and ticks (1)[A]
    - IR3535: less effective in most studies; not appropriate for malaria-endemic regions (1)[B]
  - Barrier methods: clothing, bed nets
    - Use of light-colored pants, long-sleeved shirts, and hats may reduce arthropod impact.
    - Permethrin: synthetic insecticide derived from chrysanthemum plant. Do not apply directly to skin. Permethrin-impregnated clothing provides good protection against arthropods.
  - Mosquito nets: advised for all travelers to disease-endemic areas at risk from biting arthropods. Permethrin-treated nets may offer additional protection (2)[B].
- Desensitization 75–95% effective for Hymenoptera-specific venom
  - Skin tests to determine sensitivity
  - Refer to allergist/immunologist.
- Fire ant control (but not elimination) possible
  - Baits; sprays, dusts, aerosols; biologic agents
- Risk of tick-borne diseases may be decreased by prompt removal of ticks within 24 hours of attachment.

**DIAGNOSIS**

**HISTORY**
- Sudden onset of pain or itching with visualization of arthropod
- Many cases unknown to patient or asymptomatic initially (bed bugs, lice, scabies, ticks).
  - Consider in patients presenting with localized erythema, urticaria, wheals, papules, pruritus, or bullae.
- May identify insect by its habitat or by remnants brought by patient
● History of prior exposure useful but not always available or reliable
● Travel, occupational, social, and recreational history

PHYSICAL EXAM
● If stinger is still present in skin, remove by flicking or scraping away from skin.
● Anaphylaxis is a clinical diagnosis. Signs and symptoms include (3)[A]:
  – Erythema, urticaria, angioedema
  – Itching/edema of lips, tongue, uvula; drooling
  – Respiratory distress, wheeze, repetitive cough, stridor, dysphonia
  – Hypotension, dysrhythmia, syncope, chest pain
● If anaphylaxis not present, exam focuses on the sting or bite itself. Common findings include local erythema, swelling, wheals, urticaria, papules, or bullae; excoriations from scratching
● Thorough exam to look for arthropod infestation (lice, scabies) or attached ticks. Body lice usually found in seams of clothing; skin scraping to identify scabies
● Signs of secondary bacterial infection after 24 to 48 hours: increasing erythema, pain, fever, lymphangitis, or abscess

DIFFERENTIAL DIAGNOSIS
● Urticaria and localized dermatologic reactions:
  – Contact dermatitis, drug eruption, mastocytosis, bullous diseases, dermatitis herpetiformis, tinea, eczema, vasculitis, pityriasis, erythema multiforme, viral exanthem, cellulitis, abscess, impetigo, folliculitis, erysipelas, necrotizing fasciitis
● Anaphylactoid-type reactions
  – Cardiac, hemorrhagic, or septic shock; acute respiratory failure, asthma; angioedema, urticarial vasculitis; flushing syndromes (catecholamines, vasoactive peptides); syncope
  – Differential diagnosis of the acute abdomen should include black widow spider bite.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Seldom needed; basic lab parameters usually normal

Follow-Up Tests & Special Considerations
● Severe envenomations may affect organ function and require monitoring of lab values (CBC, comprehensive metabolic panel, prothrombin time/international normalized ratio).
● Potential arthropod-borne diseases:
  – Ticks: Lyme disease, Rocky Mountain spotted fever, relapsing fever, anaplasmosis, babesiosis, tularemia; ehrlichiosis, Powassan disease; Heartland virus (HRTV); Bourbon virus
  – Flies: tularemia, leishmaniasis, African trypanosomiasis, bartonellosis, loiasis
  – Fleas: plague, tularemia, murine typhus
  – Chigger mites: scrub typhus
  – Body lice: epidemic typhus, relapsing fever
  – Kissing bugs: Chagas disease
  – Mosquitoes: malaria, yellow fever, dengue fever, West Nile virus, equine encephalitis, chikungunya, Zika virus
● With history of anaphylaxis, significant systemic symptoms, progressively severe reactions, refer to allergist for formal testing (3)[B].
**Diagnostic Procedures/Other**
Skin and immunologic tests available to identify specific allergens

---

**TREATMENT**
Most studies are retrospective or based on clinical observations.

**ALERT**
- Rapid anaphylaxis is severe and potentially life-threatening. Most deaths due to anaphylaxis occur within 30 to 60 minutes of sting.
- Give epinephrine as soon as diagnosis of anaphylaxis is suspected. Delay is associated with increasing rates of fatality (3,4)[A].
- Antihistamines and steroids do not replace epinephrine and are never initial therapy in anaphylaxis; no direct outcome data regarding their effectiveness in anaphylaxis available (3) [A]
- Airway management critical for angioedema

**GENERAL MEASURES**
Management directed at relieving itching, pain, and swelling; local wound care, ice compress, analgesics

**MEDICATION**

**First Line**
- For arthropod bites/stings with anaphylaxis
  - Expert opinion consensus (3)[C]
  - Epinephrine: most important: IM injection in midanterolateral thigh
    - IM injection: epinephrine 1:1,000 (1 mg/mL): adult: 0.3 to 0.5 mg per dose; pediatric: Give 0.01 mg/kg to a maximum dose of 0.3 mg per dose, can repeat every 5 to 15 minutes to total of three injections (3,4)[A].
  - Oxygen up to 100%, as needed
  - IV fluids: Establish 1 to 2 large-bore IV lines. Normal saline bolus 1 to 2 L IV; repeat as needed (pediatrics 20 to 30 mL/kg) (4)[A].
  - H<sub>1</sub> antagonists: diphenhydramine 25 to 50 mg IV (pediatrics 1 to 2 mg/kg) (3)[A]
  - H<sub>2</sub> antihistamines: ranitidine 50 mg IV (4)[A]
  - β<sub>2</sub> Agonists: albuterol for bronchospasm nebulized 2.5 to 5.0 mg in 3 mL (4)[A]
  - Corticosteroids: 2012 Cochrane review showed no benefit in acute anaphylaxis (4)[A]. May be of benefit in preventing biphasic allergic reactions (4)[C]; prednisone, methylprednisolone frequently used
- Arthropod bites/stings without anaphylaxis
  - Tetanus booster, as indicated
  - Oral antihistamines may be helpful.
    - Diphenhydramine adults: 25 to 50 mg PO/IV/IM every 4 to 6 hours. Pediatrics: 1 to 2 mg/kg to a max dose of 50 mg PO/IV/IM; daily maximum dose of 300 mg for adults and pediatrics
    - Cetirizine adults: 5 to 10 mg PO daily; pediatrics: 6 to 23 months—2.5 mg PO daily; 2 to 5 years—5 mg PO daily; 6 years and older—5 to 10 mg PO daily
- H₂ blockers: ranitidine adults: 150 mg PO 1 to 2 times daily as needed; pediatrics: 2 to 4 mg PO 1 to 2 times daily as needed
  - Oral steroids: Consider short course for severe pruritus or local reactions; prednisone or prednisolone 1 to 2 mg/kg once daily
  - Consider topical steroid cream or ointment for 3 to 5 days.
    - OTC 1% hydrocortisone
    - May consider higher potency such as triamcinolone 0.1%, fluocinolone 0.025%
  - Wound care: antibiotics only if infection
  - Other specific therapies:
    - Scorpion stings: Treat excess catecholamine release (nitroprusside, prazosin, β-blockers). Atropine for hypersalivation (4). Only one FDA-approved scorpion antivenom in United States. Use only in consultation with toxicologist. Black widow bites: Treat muscle spasms with benzodiazepines and opioid analgesics (4). Antivenom: for severe symptoms only (5)[B]; available but should be administered in conjunction with toxicologist
    - Consult poison control hotline for questions regarding management: 1-800-222-1222.
  - Fire ants: characteristically cause sterile pustules; leave intact—do not open or drain.
  - Brown recluse spider: pain control, supportive treatment; surgical consult if débridement needed
  - Ticks: early removal
  - Pediculosis: head, pubic, and body lice
    - First line: permethrin 1% topical lotion
    - Alternatives: Pyrethrins, ivermectin orally shown to be effective but not FDA-approved for pediculosis.
    - Repeat treatment in 7 to 10 days.
  - Sarcoptes scabiei scabies
    - Permethrin 5% cream is drug of choice: Apply to entire body. Wash off after 8 to 14 hours. Repeat in 1 week.
    - Ivermectin: 200 μg/kg PO once; repeat in 2 weeks shown to be effective but not FDA-approved for scabies.

**ISSUES FOR REFERRAL**
Patients with history of anaphylaxis, severe systemic symptoms, or progressively severe reactions benefit from consultation with allergy/immunology.

**SURGERY/OTHER PROCEDURES**
Débridement and delayed skin grafting may be needed for severe brown recluse spider and other bites.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Cool compresses
- Calamine lotion not shown to have benefit.
- A paste of 3 tsp of baking soda and 1 tsp water may help salve bites.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Anaphylaxis, vascular instability, neuromuscular events, pain, GI symptoms, renal damage/failure
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Venom immunotherapy is the cornerstone of treatment for Hymenoptera; 80–98% effective (3)[A].
- Provide epinephrine for patient self-administration if history of anaphylaxis (3)[A]. Consider “med-alert” identifiers.

Patient Monitoring

- Monitor for delayed effects, including infectious diseases from arthropod bites.
- Serum sickness reactions, vasculitis (rare)

PATIENT EDUCATION

Arthropod avoidance and preventive measures

PROGNOSIS

- Excellent for local reactions
- For systemic reactions, best response with early intervention to prevent cardiorespiratory collapse

COMPLICATIONS

- Scarring
- Secondary bacterial infection
- Arthropod-associated infectious diseases
- Psychological effects, phobias

REFERENCES

ADDITIONAL READING

22, 2018.

**CODES**

**ICD10**
- T63.481A Toxic effect of venom of arthropod, accidental, init
- T63.301A Toxic effect of unsp spider venom, accidental, init
- T63.484A Toxic effect of venom of oth arthropod, undetermined, init

**CLINICAL PEARLS**
- Urgent administration of epinephrine is the key to successful treatment of anaphylaxis.
- Local treatment and symptom management are sufficient in most insect bites and stings.
- Tick-borne illness is on the rise in the United States.
ASCITES
Sara Elsayed, MD  ● Ahmed Aldabdob, MD

BASICS

DESCRIPTION
- Accumulation of fluid in the peritoneal cavity; may occur in conditions that cause generalized edema
- Refractory ascites; ascitic fluid that recurs after paracentesis or cannot be prevented by treatment
- Men generally have no fluid in peritoneal cavity; women may have up to 20 mL depending on menstrual phase.

EPIDEMIOLOGY
- Children: most commonly associated with nephrotic syndrome and malignancy
- Adults: cirrhosis (81%), cancer (10%), heart failure (3%), other (6%)

Incidence
~50–60% of cirrhotic patients develop ascites within 10 years (1). The presence of ascites in cirrhotic patients is a poor prognostic indicator with a survival rate of 50% at 2 years.

Prevalence
10% of patients with cirrhosis have ascites.

ETIOLOGY AND PATHOPHYSIOLOGY
- Portal hypertension versus nonportal hypertension causes
  - Cannot reliably establish/confirm etiology without paracentesis
  - Serum-ascites albumin gradient (SAAG): (serum albumin level: ascites albumin level) helps to differentiate causes
- High portal pressure (SAAG ≥1.1)
  - Cirrhosis is the most common cause of ascites in the U.S.
  - Hepatitis (alcoholic, viral, autoimmune, medications)
  - Acute liver failure
  - Liver malignancy (primary or metastatic)
  - Elevated right-sided filling pressures from heart failure or constrictive pericarditis
  - Hepatic venous thrombosis (Budd-Chiari syndrome)
  - Portal vein thrombosis
- Normal portal pressure (SAAG <1.1)
  - Peritoneal carcinomatosis
  - Tuberculosis
  - Severe hypoalbuminemia (nephrotic syndrome; severe enteropathy with protein loss)
  - Meigs syndrome (ovarian cancer)
  - Lymphatic leak (chylous ascites)
  - Pancreatitis
  - Inflammatory (vasculitis, lupus serositis, sarcoidosis)
  - Other infections (parasitic, fungal)
Pathogenesis of ascites in the setting of portal hypertension (cirrhotic ascites).

Most ascites is due to portal hypertension leading to backward transmission of increased pressure to the visceral capillaries with subsequent dilation and shift of fluid to the peritoneal cavity. This dilation further increases portal pressures and decreases systemic blood volume with resultant hypotension. Systemic hypovolemia stimulates neurohormonal mechanisms (renin angiotensin system and antidiuretic hormone) for sodium retention as an attempt to compensate for decreased systemic volume and pressure.

RISK FACTORS
- Cirrhosis—Hepatitis B & C; alcohol abuse;
- Congestive heart failure (CHF); advanced kidney disease; malignancy
- Tuberculosis

DIAGNOSIS

HISTORY
- Address risk factors (e.g., EtOH use, tuberculosis (TB) exposure, prior malignancies, sexual partners, transfusion history, metabolic syndrome, increased risk of nonalcoholic steatohepatitis progressing to cirrhosis, previous history of cardiac illness).
- Assess for symptoms of underlying disease (chest pain, dyspnea, orthopnea, peripheral edema, asterixis, weight loss, night sweats, chronic cough)
- Assess for complications (fever/abdominal pain might indicate spontaneous bacterial peritonitis (SBP), progressive dyspnea due to increased abdominal girth)
- Progressive abdominal distention may be painful.

PHYSICAL EXAM
- Abdominal distention with flank/shifting dullness is the most sensitive (83%) and specific (56%) exam finding; requires >1,500 mL of fluid to detect.
- Signs of right-sided heart failure suggesting cardiac cirrhosis
- Edema (penile/scrotal, pedal), increased jugular venous pressure.
- Stigmata of chronic liver cirrhosis (palmar erythema, spider angiomata, dilated abdominal wall collateral veins)
- Other signs of advanced liver disease: jaundice, muscle wasting, gynecomastia, leukonychia, asterixis.
- Signs of underlying malignancy: cachexia; supraclavicular (Virchow) node suggests upper abdominal malignancy.

DIFFERENTIAL DIAGNOSIS
- Obesity
- Large ovarian tumors
- Bowel obstruction
- Massive splenomegaly

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Ultrasound (can detect small volumes of ascitic fluid ~100 mL)
Diagnostic paracentesis for fluid analysis to determine etiology and rule out infection in all inpatients and outpatients with clinically new-onset ascites

- Paracentesis complication rate is 1%. The presence of coagulation abnormalities does not preclude paracentesis, unless there is evidence of disseminated intravascular coagulopathy or primary fibrinolysis (1).
- Routine attempts to correct platelet or coagulation defects not needed prior to paracentesis
- Ascitic fluid analysis (1)[C]:
  - Cell count and differential:
    - Polymorphonuclear (PMN) leukocytes ≥250 cells/mm³ is diagnostic of SBP.
    - Albumin to calculate SAAG (Obtained by subtracting ascitic fluid albumin from serum albumin obtained on the SAME day):
      - <1.1 g indicates a low portal pressure exudative process (i.e., inflammatory, biliary/pancreatic, carcinomatosis, TB).
      - ≥1.1 g indicates portal hypertensive/transudative process (cirrhosis, CHF, constrictive pericarditis, thrombosis).
  - Total protein (low in cirrhosis, nephrotic disease and high in cardiac ascites) Levels less than 10 gm/dl in cirrhotic patients without SBP indicate increased risk and warrant antibiotic prophylaxis.
- Other tests (based on clinical scenario to rule out etiologies other than cirrhosis) (1)[C]:
  - Bacterial Gram stain/culture if infection suspected (Cirrhotic patients with ascites can fail to mount fever or leukocytosis.)
  - Fluid cultures are traditionally positive in 50–90% of cases of SBP.
  - Yield is improved if inoculated to blood culture bottles at bedside and if fluid is obtained before first dose of antibiotics.
  - Amylase (suspicion for bowel perforation, choledocholithiasis, or pancreatitis)
  - Triglyceride if fluid appears milky
  - Cytology if concern for malignancy (less sensitive in the absence of carcinomatosis)
  - Lactate dehydrogenase (LDH): An ascitic fluid–to–serum LDH ratio >1.0 can indicate infection, perforation, or tumor.
    - Carcinoembryonic antigen and alkaline phosphatase (elevated in viscous perforation)
- Mycobacterial culture/polymerase chain reaction for suspicion of TB
- Blood urea nitrogen/creatinine, electrolytes (renal function)
  - Brain natriuretic peptide (heart failure)
  - Liver function tests and hepatitis serologies (hepatitis)
- Abdominal ultrasound (US) can confirm ascites; highly sensitive, cost-effective, involves no radiation
- Portal US Doppler can detect thrombosis or cirrhosis.
- CT scan for intra-abdominal pathology (malignancy)
- MRI preferred for evaluation of liver disease or confirmation of portal vein thrombosis

Diagnostic Procedures/Other
Laparoscopy: if imaging and paracentesis are nondiagnostic
- Allows for direct visualization and biopsy of peritoneum, liver, and intra-abdominal lymph nodes
- Preferred for evaluating suspected peritoneal TB or malignancies

Test Interpretation
Cytology may reveal malignant cells: adenocarcinoma (ovary, breast, GI tract) or primary peritoneal carcinoma (most commonly associated with ascites).

**TREATMENT**

For all patients, first-line treatment consists of:

- Daily weight
- Restrict dietary sodium to ≤2 g/day if the cause is due to portal hypertension (high SAAG).
- Water restriction (1.0 to 1.5 L/day) only necessary if serum sodium <120 to 125 mEq/L
- Avoid alcohol and ensure adequate nutrition if liver disease.
- Baclofen may be used to reduce alcohol craving/consumption in EtOH cirrhosis.

**MEDICATION**

**ALERT**

- Care with diuresis; aggressive diuresis can induce prerenal acute kidney injury (AKI), encephalopathy, and hyponatremia. Monitor creatinine and electrolytes closely. Serum creatinine >2 mg/dL or serum sodium <120 mmol/L warrants withdrawal of diuretics.
- Avoid nonsteroidal anti-inflammatory drugs (can exacerbate oliguria/azotemia).
- Angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) may be harmful in patients with cirrhosis/ascites due to an increased risk of hypotension and renal failure. Avoid in refractory ascites.
- Consider discontinuing β-blockers in patients with refractory ascites, SBP, worsening hypotension (SBP <90 mm hg), AKI, hyponatremia <130 mEq/L, or azotemia.

**First Line**

- Sodium restriction and diuretics are the mainstay of treatment for patients with elevated portal pressures; other causes (e.g., carcinomatosis) are less likely to respond to medical therapy.
  - Spironolactone 100 to 400 mg daily PO; typical initial dose is 100 to 200 mg given in am.
    - Diuretic of choice due to antialdosterone effects; can be used as single agent in minimal ascites. Monitor for hyperkalemia.
  - Furosemide 40 to 160 mg daily PO; typical initial dose is 40 mg given in am.
    - Antinatriuretic effect helps achieve negative sodium balance.
    - Preferred in combination with spironolactone rather than as monotherapy
  - Most common (and preferred) regimen is spironolactone and furosemide together (maintaining a 100:40 ratio) for maximum efficacy and to maintain potassium homeostasis.
    - Titrate dose to desired result (1–Daily weight loss no more than 0.5 kg/day in patients without peripheral edema and 1 kg/day in patients with peripheral edema. 2–Urinary sodium output more than the sodium intake.), and monitor renal function regularly.
    - Follow daily weight.
    - Adjust ratio to maintain normal potassium.
  - Diuretic-intractable/refractory ascites (RA) (10% of patients—50% mortality in 6 months) defined as:
    - 1) Persistent or worsening ascites despite maximum doses of spironolactone (400 mg/day) and furosemide (160 mg/day) for at least 1 week
    - 2) Recurrence of grade 2 or 3 ascites within 4 weeks of achieving minimal ascites
    - 3) Diuretic induced complications like hepatic encephalopathy, hyponatremia to <125
mEq/L, renal impairment with creatinine rise of 100% to more than 2.0

- **Treatment:**
  - Ensure compliance with dietary sodium restriction using 24-hour urine sodium excretion:
    - Discontinue diuretics if urinary sodium excretion under diuretic therapy is less than 30 mmol/day.
    - Therapeutic paracentesis or serial large-volume paracentesis (LVP) (see “Surgery/Other Procedures”).
    - IV furosemide reduces eGFR dramatically in ascitic patients and is better avoided.

**Second Line**
- Midodrine 7.5 mg TID can be used for refractory ascites or hypotensive patients, it was found to improve response to diuretics, improve hyponatremia, mean arterial pressure, and may improve survival [1][B]. Titrate to blood pressure response.
- Alternatives to spironolactone: amiloride up to 40 mg/day; triamterene up to 200 mg/day in divided doses [1][C]
- Alternatives to furosemide: torsemide up to 100 mg/day; bumetanide up to 4 mg/day [1][C]
- Vaptans may have a beneficial effect on hyponatremia and ascites, but routine use in ascites is not yet supported. FDA has recommended to avoid use in chronic liver disease due to potential to induce serious liver injury [2][A].

**ISSUES FOR REFERRAL**
Liver transplant is the definitive treatment for portal hypertension. Consider referral for transplant in patients with decompensated liver disease, whether or not ascites is present/controlled [1][B].

**SURGERY/OTHER PROCEDURES**
- Therapeutic paracentesis
  - Initial therapy if tense ascites is present [1][C]
  - Serial (generally every 2 weeks) paracenteses can be used as second line after diuretics in patients with elevated portal pressures.
  - Complications: infection, hemodynamic collapse, acute renal failure
  - Similar complication rate as diuretics
  - Replace albumin when removing >5 L of ascites: 5.5 to 8.0 g albumin for each liter removed. Albumin replacement decreases renal dysfunction, postparacentesis hyponatremia, and overall morbidity; likely not needed for malignant ascites
  - Continue diuretics at 50% of the previous dose if transitioning to serial paracentesis in patients failing diuretic monotherapy.
- Transjugular intrahepatic portosystemic shunt (TIPS)
  - Only for patients with elevated portal pressures with refractory ascites
  - Fluoroscopically placed conduit from portal to hepatic vein for intractable ascites
    - At time of placement, portal pressure should drop ≥20 mm Hg (or to <12 mm Hg), and ascites should be controllable with diuretics.
    - Yearly US to confirm shunt function
    - 4 weeks after TIPS, urinary sodium and serum creatinine improve significantly and can normalize after 6 to 12 months in combination with diuretics. Shunt dilation and/or replacement may be required after 2 years.
    - TIPS is superior to paracentesis for controlling ascites; no difference in mortality
Automated low-flow ascites pump drains ascitic fluid from peritoneal cavity to urinary bladder for elimination. Mainly used in patients with contraindication to TIPS placement or liver transplant.

- Cell free and concentrated ascites reinfusion:
  - Used for management of malignant ascites. Protein collected from filtration and concentration of ascitic fluid is reinfused intravenously

- Peritoneovenous shunt (LeVeen or Denver shunt): drains ascites directly into the inferior vena cava
  - Trials show poor long-term shunt patency, no survival advantage.
  - Complications include bacteremia, bowel obstruction, and variceal bleed.
  - Reserved for patients with refractory ascites who are not candidates for TIPS or liver transplant and who can't tolerate repeat paracentesis (1)[C]

- Indwelling catheters with external drainage
  - Most useful in malignant ascites as a palliative measure (can be drained at home)
  - Overall low rate of infection

- Avoid percutaneous endoscopic gastrostomy (PEG) tube placement in patients with ascites due to high postprocedure mortality rate (1)[B].

**ONGOING CARE**

**PROGNOSIS**

- Prognosis varies depending on underlying cause.
- Ascites in itself is rarely life-threatening but can signify life-threatening underlying disease (e.g., cancer, end-stage liver disease).

**COMPLICATIONS**

- **SBP**
  - Ascitic fluid PMN leukocyte count ≥250 cells/mm$^3$ or positive culture
    - Broad-spectrum antibiotics are as follows: Cefotaxime 2 g q8h or similar 3rd-generation cephalosporin is the treatment of choice for suspected SBP; covers 95% of flora (including Escherichia coli, Klebsiella, pneumococci) (1)[A]; broader coverage often required for hospital-acquired infections
    - Levofloxacin is an alternative for patients who are not on long-term fluoroquinolones or who are allergic to penicillins or β-lactams.
    - Consider SBP prophylaxis in: GI bleeding, previous SBP episode, or ascitic fluid protein less than 10 g hospitalized for reasons other than SBP.
    - Suspect primary bacterial peritonitis (PBP) due to bowel perforations when ascitic fluid >250 cells/mm$^3$ (often >5,000 cells/mm$^3$) and any two of the following:
      - Ascitic fluid total protein >1 g/dL (often >3 g/dL)
      - Ascitic fluid glucose <50 mg/dL (or 2.8 mmol/L)
      - Ascitic fluid LDH that is 3-fold greater than serum LDH

- Hepatorenal syndrome: Type 1: rapid acute worsening of renal function evolving in the setting of a known precipitating factor. Type 2 is more slowly progressive in the setting of refractory ascites.

- Cellulitis is common in obese patients with brawny edema. Treat with diuretics and antibiotics
REFERENCES

SEE ALSO
• Cirrhosis of the Liver; Hepatorenal Syndrome
• Algorithms: Congestive Heart Failure: Differential Diagnosis; Nephrotic Syndrome

CODES

ICD10
• R18.8 Other ascites
• R18.0 Malignant ascites
• K70.31 Alcoholic cirrhosis of liver with ascites

CLINICAL PEARLS
• Cirrhosis is the most common cause of ascites.
• Patients with new-onset ascites or hospitalized patients with ascites should undergo diagnostic paracentesis.
• Avoid ACE inhibitors, ARBs, and β-blockers in patients with ascites.
• Most common cause of “diuretic-intractable ascites” is nonadherence with dietary sodium restriction.
• Diuretics are first-line agents in the treatment of ascites. Serial paracentesis or TIPS are second line.
ASTHMA
Stacy Potts, MD, MEd

BASICS

DESCRIPTION

- A heterogeneous disease characterized as chronic inflammation of the airway; patients present with history of wheeze, shortness of breath (SOB), chest tightness, and cough which varies in time and intensity along with variable expiratory flow (1).
- Common triggers: exercise, allergen-irritant exposure, change in weather, laughter, or viral respiratory infections
- Patient may experience symptoms-free periods alternating with sporadic flare-up (exacerbations).
- Most common asthma phenotypes:
  - Allergic asthma: usually present since childhood and has strong family history of allergic diseases
  - Nonallergic asthma
  - Late-onset asthma: more common in females
  - Asthma with fixed airflow limitation: due to airway remodeling
  - Asthma with obesity
- Four major classifications of asthma severity used primarily to initiate therapy (2):
  - Intermittent: symptoms ≤2 days/week, nighttime awakenings ≤2 times per month, short-acting β-agonist (SABA) use ≤2 days/week, no interference with normal activity, and normal forced expiratory volume in 1 second (FEV₁) between exacerbations with FEV₁ (predicted) >80% and FEV₁/FVC normal for age
  - Mild persistent: symptoms >2 days/week but not daily, nighttime awakenings 3 to 4 times per month, SABA use >2 days/week but not daily, minor limitations in normal activity, and FEV₁ (predicted) >80% and FEV₁/FVC normal for age
  - Moderate persistent: daily symptoms, nighttime awakenings >1 times per week but not nightly, daily use of SABA, some limitation in normal activity, and FEV₁ (predicted) 60–80% and FEV₁/FVC reduced 5% for age
  - Severe persistent: symptoms throughout the day, nighttime awakenings often 7 times per week, SABA use several times a day, extremely limited normal activity, and FEV₁ (predicted) <60% and FEV₁/FVC reduced >5% for age

EPIDEMIOLOGY

Prevalence
Asthma affects 235 million individuals worldwide.
- 383,000 deaths worldwide reported in 2015
- Asthma affects about 10% of children ages 5 to 18 years in the United States.
- Asthma prevalence is greater in boys than girls; however, in adults, women are more affected.
- Obesity is associated with increased prevalence and incidence of asthma, especially in women with abdominal obesity.
ETIOLOGY AND PATHOPHYSIOLOGY
Airway hyperreaction begins with inflammatory cell infiltration and degranulation, subbasement fibrosis, mucus hypersecretion, epithelial injury, significant smooth muscle hypertrophy and hyperreactivity, angiogenesis that then leads to intermittent airflow obstruction due to reversible bronchospasm (3).

Genetics
- Genetic association with increased interleukin (IL) production and airway hyperresponsiveness leading to asthma; genome-wide association studies (GWAS) show genetic predisposition leading to increased production of IgE, which increased chances of developing the disease.
- Variations in genetic coding have been linked to different levels of response to treatment, which is a key factor for controlling the disease and decreasing rates of exacerbation.

RISK FACTORS
- Host factors: genetic predisposition, sex, race, obesity, preterm or small for gestational age (SGA)
- Environmental: viral infections, animal and airborne allergens, tobacco smoke exposure, pollution, stress
- Aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs) hypersensitivity or β-blockers
- Persons with food allergies and asthma are at increased risk for fatal anaphylaxis from those foods (2).

COMMONLY ASSOCIATED CONDITIONS
- Atopy: eczema, allergic conjunctivitis, allergic rhinitis
- Obesity (associated with higher asthma rates)
- Sinusitis
- Gastroesophageal reflux disease (GERD)
- Obstructive sleep apnea (OSA)
- Depression

DIAGNOSIS

HISTORY
History of variable respiratory symptoms:
- More than one symptom such as wheeze, SOB, cough, chest tightness
- Symptoms worse at night, vary in time and intensity, worse with common triggers

PHYSICAL EXAM
- May be normal
- Focus on
  - General appearance: signs of respiratory distress such as use of accessory muscles
  - Upper respiratory tract: rhinitis, nasal polyps, swollen nasal turbinates
  - Lower respiratory tract: expiratory wheezing, prolonged expiratory phase. Note: Wheezing may be absent in severe exacerbation due to severely reduced airflow.
  - Skin: eczema

DIFFERENTIAL DIAGNOSIS
In children
- Upper airway diseases (allergic rhinitis or sinusitis)
- Large airway obstruction (foreign body aspiration, vocal cord dysfunction, vascular ring or laryngeal web, laryngotracheomalacia, enlarged lymph nodes, or tumor)
- Small airway obstruction (viral bronchiolitis, cystic fibrosis, bronchopulmonary dysplasia, heart disease, primary ciliary dyskinesia, bronchiectasis)
- Other causes (recurrent cough not due to asthma, chronic upper airway cough syndrome, aspiration/GERD)

In adults
- Chronic obstructive pulmonary disease, bronchiectasis, heart failure, pulmonary embolism, benign or malignant tumor, pulmonary infiltration with eosinophilia, Churg-Strauss syndrome, medication-induced cough (ACE inhibitors), vocal cord dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Blood tests are not required but may find eosinophilia or elevated serum IgE levels (allergic asthma).
- Documented variable expiratory airflow limitation:
  - Spirometry: Normal test does not rule out asthma; measures the FVC and the FEV₁; a reduced predicted ratio of FEV₁/FVC with reversibility (increase of 200 mL and 12% of FEV₁/FVC from baseline) after using a short-acting bronchodilator (SABA)
  - Excessive variability in twice daily; peak expiratory flow (PEF) in 2 weeks (daily diurnal PEF variability >10%)
  - Bronchial challenge test: used mainly in adults, positive when there is a fall in FEV₁ >20% with methacholine or histamine; or >15% with hypertonic saline or mannitol challenge
  - Exercise challenge test: fall in FEV₁ >10% and 200 mL from baseline
  - Significant increase in lung function after 4 weeks of anti-inflammatory treatment
- Chest x-ray is used to exclude alternative diagnoses and to evaluate patients for complicating cardiopulmonary processes.

Follow-Up Tests & Special Considerations
- Asthma action plan: Patients monitor their own symptoms and/or peak flow measurements. Reassess action plan every 3 to 6 months.
- Assess asthma symptoms control with simple screening tools, such as consensus-based GINA symptom control tool or Primary Care Asthma Control Screening Tool (PACS).

Diagnostic Procedures/Other
- Allergy skin testing is not useful for diagnosis of asthma but may be to evaluate atopic triggers.
- Measurement of fractional concentration of exhaled nitric oxide (FENO), widely available although not useful for ruling in or ruling out diagnosis of asthma. FENO suggests eosinophilic airway inflammation which can be elevated in other conditions than asthma, such as eosinophilic bronchitis.

TREATMENT
GENERAL MEASURES

- Focus on symptom control and prevention of exacerbations.
- Use Asthma Management Cycle: Assess, Adjust, Review Response
- Use of holding chambers (“spacers”) with inhaled agents improves clinical outcomes.
- Written asthma self-management action plan
- Encourage physical activity, weight loss, smoking cessation, avoidance of irritants, emotional stress.
- Avoidance of occupational exposure
- Annual influenza vaccine
- Pneumococcal vaccine recommended for high-risk patients
- Patients at risk for anaphylaxis should carry an EpiPen.
- Controller medications: used for regular maintenance, reduce airway inflammation, control symptoms, and reduce risk of exacerbations:
  - Inhaled corticosteroids (ICS)
    - Beclomethasone dipropionate
    - Budesonide
    - Ciclesonide
    - Fluticasone furoate or propionate
    - Mometasone furoate
    - Triamcinolone acetonide
  - Long-acting β-agonist (LABA)
    - Formoterol
    - Salmeterol
- Reliever (rescue medication) provided to all patients for as-needed relief of breakthrough symptoms
  - SABA—albuterol/levalbuterol
- Add-on therapies for patients with severe asthma, when patients persist with symptoms despite optimized treatment with high-dose controller medications (ICS + LABA)
  - Anticholinergic agents, tiotropium (long-acting muscarinic antagonist [LAMA]) or ipratropium (short-acting muscarinic antagonist [SAMA])
  - Anti-immunoglobulin E (anti-IgE) (omalizumab) treatment
  - Leukotriene receptor antagonist (LTRA) (montelukast, pranlukast, zafirlukast)
  - Chromones (nedocromil sodium, sodium cromoglicate)
- Initial recommended controllers by patient’s presenting symptoms:
  - No controller recommended when:
    - Typical symptoms or need for SABA <2 times per month, no waking up from sleep in last month, no risk factor for exacerbations, no exacerbation in the past year
  - Low-dose ICS when:
    - Infrequent asthma symptoms but patient has presence of >1 risk factors for exacerbation
  - Low-dose ICS when:
    - Typical symptoms or need for SABA 2 times per month/week or patient wakes up from sleep
  - Low-dose ICS when:
    - Symptoms recurs or need for SABA >2 times per week; alternative treatment—LTRA or theophylline
  - Medium- to high-dose ICS or low-dose ICS/LABA when:
Symptoms recur most of the day, patient wakes up from sleep >1 a week, presence of risk factors for asthma exacerbation
- Short course of oral corticosteroids (OCS) plus regular controller treatment—high-dose ICS or moderate-dose ICS/LABA (budesonide/formoterol; beclomethasone/formoterol) when:
  - Severe uncontrolled asthma or acute exacerbation
- Stepwise approach for asthma treatment for adolescents (>12 years) and adults:
  o Step 1: symptom driven treatment:
    ■ First: symptom driven low dose ICS, inhaled SABA; alternatives: daily low-dose ICS
  o Step 2: low-dose controller + as needed reliever:
    ■ First: low-dose ICS + SABA; alternatives for controllers: second: LTRA; third: low-dose ICS/LABA
  o Step 3: one or two controllers + as needed reliever:
    ■ First (adults/adolescents): low-dose ICS/LABA + SABA or ICS/formoterol as both controller + reliever; first (ages 6 to 11 years) and second alternative (adults/adolescents): moderate-dose ICS + SABA; third: low-dose ICS + LTRA versus low-dose sustained-release theophylline
  o Step 4: two or more controllers + as needed reliever:
    ■ First (adults/adolescents): low-dose ICS/formoterol as both controller + reliever OR moderate-dose ICS/LABA + SABA; first (ages 6 to 11 years): referral to specialist; alternative: second: LAMA, sustained-release theophylline or LTRA as add-on therapy
  o Step 5: referral to specialist and add-on therapy (i.e., LAMA, anti-IgE, anti-IL5)
  - Combination therapy with a LABA ICS resulted in fewer asthma exacerbations than treatment with ICS alone (3).

Pediatric Considerations
- Theophylline should not be used in children.
- Tiotropium is not indicated in children <12 years.

Pregnancy Considerations
- Do not use bronchial provocation test nor step down controller treatment until after delivery.
- Asthma symptoms tend to worsen in 1/3 of patients, 1/3 improves, and 1/3 remains unchanged.
- Exacerbations are common in 2nd trimester.
- Poorly controlled asthma results in low birth weight, increased prematurity, and perinatal mortality.
- All short-acting agents (SABA) are pregnancy Category C as well as ICS.
- ICS prevents asthma exacerbation during pregnancy.
- Cessation of ICS during pregnancy is a significant risk factor for exacerbation.
- Montelukast and zafirlukast are Category B but are not studied extensively in pregnancy.

Geriatric Considerations
- Underdiagnosed due to comorbidities; electrocardiogram (ECG), echocardiogram, and measurement of plasma brain natriuretic peptide (BNP) may be helpful in diagnosis.
- Management challenges due to comorbidities (like arthritis) and due to polypharmacy

ISSUES FOR REFERRAL
- Specialized testing (e.g., bronchoprovocation)
- Specialized treatments (e.g., immunotherapy, anti-IgE therapy)
- Poorly controlled asthma, frequent exacerbation, or multiple ED visits
Occupational asthma if suspected, refer for consultation due to legal implications.

ADDITIONAL THERAPIES
- Exercise-induced bronchoconstriction (EIB): Pharmacotherapy show to reduce symptoms, SABA prior exercise, or LTRA/chromones.
- Athletes: Limit exertion in extreme cold or pollution.
- Allergen immunotherapy when clear relationship between symptoms and exposure to an unavoidable allergen
- Bronchial thermoplasty involves treatment of the airway.
- Management of acute exacerbation of asthma
  - Outpatient:
    o Mild: speak in full sentence, heart rate (HR) <120 bpm, oxygen saturation 90–95%, and peak flow >50% of predicted can be managed as outpatient in clinic; should start SABA and prednisolone; if symptoms resolve within 1 hour, could be discharge home with close follow-up
    o Severe symptoms: not able to speak in full sentence, HR >120 bpm, oxygen saturation <90%, peak flow <50% predicted, drowsy, confused, or silent chest; transfer to inpatient facility.
  - Treatment for severe:
    o Oxygen: to maintain saturation 93–95%
    o SABA: within 1 hour of arrival, initially around the clock followed by on demand
    o Systemic steroids: Oral is as effective as IV. 50 mg prednisolone (morning dose) or 200 mg hydrocortisone divided in doses. Duration should be 5 to 7 days.
    o Epinephrine: only when asthma is associated with angioedema or anaphylaxis
    o Avoid sedative.
    o Careful respiratory monitoring including vital signs, pulse oximetry, response and duration of response to SABA, and when possible, an objective measure of lung function such as PEF or FEV₁
  - Discharge criteria
    o Minimal or absent asthma symptoms
    o Hypoxia has resolved.
    o FEV₁ or PEF ≥70% predicted or personal best
    o Bronchodilator response sustained ≥60 minutes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Identify triggers and control exposures.
- Consider stepping down treatment once symptoms are controlled for 3 months and patient is at low risk for exacerbation.

PATIENT EDUCATION
- American Academy of Allergy, Asthma & Immunology: 800-822-2762 or http://www.aaaai.org/
- American Lung Association: 800-586-4872 or http://www.lung.org/
PROGNOSIS
Prognosis is good for male patients, nonsmokers, and children with mild disease.

COMPLICATIONS
- Atelectasis
- Pneumonia
- Air leak syndromes: pneumomediastinum, pneumothorax
- Medication-specific side effects/adverse effects/interactions
- Respiratory failure
- Death: ~50% of asthma deaths occur in the elderly (age >65 years), and mortality is increasing in that population.

REFERENCES

CODES

ICD10
- J45.20 Mild intermittent asthma, uncomplicated
- J45.52 Severe persistent asthma with status asthmaticus
- J45.51 Severe persistent asthma with (acute) exacerbation

CLINICAL PEARLS
- SABA is the most effective rescue therapy for acute asthma symptoms.
- Holding chambers should be used by all.
- ICSs are the preferred long-term control therapy for patients of all ages. GINA 2019 recommends symptom driven ICS for early management in adolescents and adults (1).
ATELECTASIS
Keshav Kukreja, MD • Adrian DaSilva-DeAbreu, MD • Raymundo A. Quintana, MD

BASICS

DESCRIPTION

- Atelectasis is defined as the incomplete expansion of lung tissue due to collapse or closure. The loss of lung volume and function leads to impaired airway mucus clearance.
- Broadly categorized as:
  - Obstructive: airway blockage
  - Nonobstructive: loss of contact between the parietal and visceral pleurae, replacement of lung tissue by scarring or infiltrative disease, surfactant dysfunction, and parenchymal compression
- Symptoms depend on the rate of collapse, the amount of lung involved, and whether the patient has underlying lung disease and/or comorbidities.
- Reduced respiratory gas exchange can cause hypoxemia.

EPIDEMIOLOGY

- Mean age is 60 years, but all ages are susceptible.
- Male = female; no racial or socioeconomic predilection

Incidence

- Rounded atelectasis can be seen in up to 65–70% of asbestos workers.
- Lobar atelectasis is variable based on the collateral ventilation and number of lobes involved.

Prevalence

Postoperative atelectasis, especially after major cardiovascular or gastrointestinal (GI) procedures; can be seen in up to 90% of patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Obstructive (resorptive) atelectasis is caused by intrinsic airway blockage and is the most common variety. It can be caused by luminal blockage (i.e., foreign body, mucus plug, asthma, cystic fibrosis, trauma, mass lesion) or airway wall abnormality (i.e., congenital malformation and emphysema).
  - Distal to the obstruction, alveolar air is rapidly reabsorbed into the deoxygenated venous system, causing complete collapse of the alveolar tissue.
  - Fraction of inspired oxygen (FiO₂): Compared to the rapid dissociation of O₂ distal to the obstruction, the 79% atmospheric nitrogen in atmospheric dissociates more slowly from the alveoli. This prevents collapse by maintaining positive pressure inside the alveoli. However, with increased FiO₂, the concentration of nitrogen is decreased, allowing rapid development of atelectasis at the onset of obstruction.
  - The patency and function of the collateral ventilatory systems in each lobe ( pores of Kohn, canals of Lambert, and fenestrations of Boren) depends on multiple patient factors including age, underlying lung disease, and FiO₂.
In patients with emphysema, the fenestra of Boren become enlarged, which acts as a compensatory mechanism and can lead to a delay in atelectasis despite an obstructing lesion or mass.

- Nonobstructive atelectasis
  - Passive atelectasis (i.e., during a pleural effusion or pneumothorax) is due to pleural membrane separation of the visceral and parietal layers.
  - Compression atelectasis occurs with space-occupying lesions, cardiomegaly, abscess, or significant lymphadenopathy.
    - Increased chest wall pressure compresses the alveoli, leading to diminished functional residual capacity (FRC) or resting lung volume.
  - Adhesive atelectasis in the setting of acute respiratory distress syndrome (ARDS), radiation, smoke inhalation, or uremia. The underlying surfactant dysfunction causes increased surface tension and alveoli collapse.
  - Cicatrization represents pleural or parenchymal scarring and is common in granulomatous disease (i.e., sarcoidosis), toxic or radiation exposure, and drug-induced fibrosis (i.e., amiodarone, cyclophosphamide).
  - Replacement atelectasis: diffuse tumor (i.e., bronchioalveolar cell carcinoma) manifestation resulting in complete lobar collapse
- Rounded atelectasis is a distinct form of atelectasis seen in patients with asbestos exposure as a result of their significant pleural disease.
- Others
  - Hypoxemia from a pulmonary embolus.
  - Muscular weakness: due to anesthesia side-effect, or in neuromuscular diseases with respiratory muscle involvement.

**Pediatric Considerations**
Children are at a higher risk of developing atelectasis due to their less developed collateral ventilation and compensatory mechanisms.

**RISK FACTORS**
- Critical care and prolonged immobilization
- General anesthesia (including long-acting muscle relaxants, postoperative epidural anesthesia)
- Positive fluid balance
- Massive blood transfusion (≥4 units)
- Nasogastric tube placement
- Hypothermia
- Mechanical ventilation with high tidal volume (Vt >10 mL/kg) and plateau pressure (>30 cm H₂O)
- Patient risk factors for postoperative atelectasis:
  - Age >60 years and <6 years
  - Chronic obstructive pulmonary disease (COPD)
  - Obstructive sleep apnea
  - Congestive heart failure (CHF)
  - Alcohol abuse, smoking
  - Pulmonary hypertension
  - Albumin <3.5 g/dL
  - Hemoglobin <10 g/dL
– BMI >27 kg/m² (weak evidence)
– ASA class II+ functional dependence in activities of daily living (ADLs)
– Surgical procedures: cardiothoracic, vascular, upper GI, neurosurgical, oromaxillofacial, and ENT.
– Often a precursor to more serious pulmonary complications postoperatively (1)

Right middle lobe syndrome (Brock syndrome): wedge-shaped density extending inferiorly and anteriorly from the hilum. Best seen on lateral chest radiography; no consistent clinical definition

GENERAL PREVENTION
– Early mobilization, deep breathing exercises, coughing, and frequent changes in body position
– Preoperative physical therapy lowered rates of atelectasis, pneumonia, and length of stay (LOS) in patients undergoing elective cardiac surgery. However, there was no change in other postoperative pulmonary complications or mortality (2)[A]. Furthermore, large RCTs are needed before conclusions can be drawn regarding the efficacy of chest physiotherapy and incentive spirometry (IS).
– Mechanical ventilation settings with high Vt (Vt >10 mL/kg) and plateau pressures (>30 cm H₂O) and without positive end-expiratory pressure (PEEP) are associated with postoperative pulmonary complications (i.e., pneumonia, respiratory failure):
  – Minimize ventilator-induced injury by employing low Vt and plateau pressures at sufficient PEEP.
  – Ensure lower FiO₂ during anesthetic induction and intraoperatively to prevent nitrogen washout.
– Continuous positive airway pressure (CPAP) during anesthesia induction and reversal of anesthesia-induced atelectasis after intubation by a recruitment maneuver may decrease postoperative pulmonary complications (3)[C].

COMMONLY ASSOCIATED CONDITIONS
– Obstructive lung diseases (COPD and asthma)
– Trauma
– ARDS, neonatal RDS, pulmonary edema, pulmonary embolism, pneumonia, pleural effusion, pneumothorax
– Respiratory syncytial virus (RSV), bronchiolitis
– Bronchial stenosis, pulmonic valve disease, and pulmonary hypertension
– Neuromuscular disorders (muscular dystrophy, spinal muscular atrophy, spinal cord injury, and Guillain-Barré syndrome) and cystic fibrosis

DIAGNOSIS

HISTORY
– Frequently asymptomatic
– Tachypnea and sudden-onset dyspnea
– Nonproductive cough
– Pleuritic pain on affected side
– History of smoking, COPD, pulmonary insufficiency, exposure to radiation, asbestos, or other air pollutants
PHYSICAL EXAM
- Signs of hypoxia or cyanosis
- Tracheal or precordial impulse displacement toward the affected side; dullness to percussion
- Bronchial breathing in patent airway
- Wheezing or absent breath sounds in occluded airway
- Diminished chest expansion

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology.”

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC and respiratory Gram stain, culture, and viral panel if infection suspected
- ABG: Despite hypoxemia, PaCO₂ level is usually normal or low.
- Chest x-ray (CXR), PA, and lateral
  - Displaced hilum, mediastinal shift toward the side of atelectatic lung, volume loss in ipsilateral hemithorax, raised diaphragm
  - Crowding of the ribs and silhouetting of the diaphragm or heart border
  - Compensatory hyperlucency of remaining lobes of affected lung and compensatory hyperinflation in unaffected lung
  - Lobar collapse
  - Wedge-shaped densities: obstructive atelectasis
  - Small, linear bands (Fleischner lines) often at lung bases: discoid (subsegmental or plate) atelectasis
  - Direct signs: displacement of fissures and opacification of the collapsed lobe. Right upper lobe collapse may display the inverted “S sign of Golden,” representing neoplastic shift of the minor fissure.
  - Air bronchograms: Pleural fluid or air may indicate compressive atelectasis.
  - Adhesive atelectasis may present as a diffuse reticular granular pattern, which can progress to a pulmonary edema pattern and to bilateral opacification in severe cases.
  - Pleural-based round density: round atelectasis
  - Complete atelectasis of entire lung: opacification of the entire hemithorax and a shift of the mediastinum to atelectatic lung.

Follow-Up Tests & Special Considerations
- Chest CT or MRI may be indicated to visualize airway and mediastinal structures and identify cause of atelectasis in unclear cases.
- Pulmonary function tests (PFTs) can help identify obstructive or restrictive disease and decreased respiratory muscle pressures.
- Hypoalbuminemia (albumin <3.5 g/L) is a powerful marker of increased risk for postoperative pulmonary complications, including atelectasis.

Diagnostic Procedures/Other
Flexible fiber-optic bronchoscopy can be considered in unexplained or refractory cases.
TREATMENT

GENERAL MEASURES
- Identify and treat the underlying etiology.
- PEEP for prevention following surgery or general anesthesia (3)[C]
- Lay on unaffected side, encourage frequent coughing, deep breathing exercises, and early mobility.
- IS every hour while awake
  - Frequently used despite lack of evidence for IS preventing postoperative pulmonary complications after coronary artery bypass grafting (CABG) (4)[A]
- Mechanical ventilate with PEEP in severe respiratory distress or hypoxemia:
  - Lower Vt (6 mL/kg) and lower plateau pressures (<30 mm Hg) associated with reduced mortality
  - PEEP 15 to 20 mL may be necessary to maintain arterial O₂ saturation in surfactant-impaired lung regions.

MEDICATION

First Line
Pharmacotherapy should address underlying etiology:
- Antibiotics for infection
- Chemotherapy or radiation for malignancy
- Inhalers and steroids for asthma
- Effective analgesia to permit deep inspiration and coughing
- Mucolytics can be considered to promote airway clearance (i.e., N-acetylcysteine and saline).

Pediatric Considerations
- Dornase alfa may be effective clearing mucinous secretions in refractory mucous plugging in children (used in cystic fibrosis).
- Chest physiotherapy (i.e., percussion, drainage, deep insufflation, and saline lavage) is the most commonly utilized therapy in the inpatient setting.
- Other physically stimulating modalities (mechanical insufflation-exsufflation, intrapulmonary percussive ventilation, intermittent positive pressure breathing) may have utility in patients with neuromuscular disease and cystic fibrosis to enhance mucus clearance.
- Applying continuous distending pressure has shown some benefit in the treatment of preterm infants with RDS and has the potential to reduce lung damage particularly if used early (5)[A].
- In obstructive atelectasis, bronchoscopy remains controversial. However, in the presence of a mucus plug or cast, bronchoscopy may be beneficial.

Second Line
Fiber-optic bronchoscopy to improve airway clearance has been efficacious in several studies; however, there is debate regarding its efficacy in the treatment of atelectasis. It may be beneficial in those with unsuccessful attempts or contraindications to chest physiotherapy (i.e., chest wall trauma).

SURGERY/OTHER PROCEDURES
Appropriate surgical resection for underlying disease (i.e., tumor, severe lymphadenopathy)
ALERT
The association between postoperative atelectasis and fever is likely coincidental rather than causal.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Ensure adequate oxygenation (may start with 100% FiO\textsubscript{2} then taper) and humidification. Note: if obstructive atelectasis is suspected, then judiciously increase FiO\textsubscript{2} to prevent nitrogen washout, which can hasten atelectasis.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Frequency/adequacy of monitoring will vary by underlying cause and concurrent comorbidities.
- For uncomplicated cases of atelectasis associated (i.e., those associated with asthma or infection), outpatient monitoring may be appropriate.

PATIENT EDUCATION
Maximize mobility as tolerated and encourage frequent coughing and deep breathing exercises. Seek further treatment or return to ED for worsening symptoms or shortness of breath.

PROGNOSIS
- Postoperative atelectasis usually spontaneous resolves within 24 hours but can persist for days.
- Resolution of lobar atelectasis due to endobronchial obstruction depends on treatment of underlying disease or malignancy.
- Surgical intervention is indicated only for resectable etiologies (i.e., tumor) or if atelectasis is severe and causes chronic infections and bronchiectasis.

COMPLICATIONS
- Pneumonia or other pulmonary infections
- Acute atelectasis: hypoxemia, respiratory failure, postobstructive drowning of the lung
- Chronic atelectasis: bronchiectasis, pleural effusion, empyema

REFERENCES

**ADDITIONAL READING**

**CODES**

ICD10
J98.11 Atelectasis

**CLINICAL PEARLS**

- Low serum albumin (<3.5 g/L) is a strong predictor of postoperative pulmonary complications, including atelectasis.
- Anesthesia-induced atelectasis occurs in almost all anesthetized patients but can be reduced by employing PEEP intraoperatively or when reversing anesthesia.
- Early mobilization, coughing, deep breathing exercises, and treating the underlying cause are the mainstays of therapy.
- Bronchogenic carcinoma can present as atelectasis and must be excluded in all patients >35 years.
- In complete atelectasis of an entire lung, the mediastinal ipsilateral shift separates atelectasis from massive pleural effusion.
- No strong clinical evidence supports atelectasis as an early cause of postoperative fever.
ATRIAL FIBRILLATION AND ATRIAL FLUTTER
Bianca Lee, DO, MS • Youhua Zhang, MD, PhD

BASICS
This topic covers both atrial fibrillation (AFib) and atrial flutter (AFlut).

DESCRIPTION
- **AFib:** paroxysmal or continuous supraventricular tachyarrhythmia characterized by rapid, uncoordinated atrial electrical activity and an irregularly irregular ventricular response. In most patients, the ventricular rate is rapid because the atrioventricular (AV) node is bombarded with very frequent atrial electrical impulses (400 to 600 bpm).
- **AFlut:** paroxysmal or continuous supraventricular tachyarrhythmia with rapid but organized atrial electrical activity. The atrial rate is typically between 250 and 350 bpm and is often manifested as “saw-tooth” flutter (F) waves on the ECG, particularly in the inferior leads and V1. AFlut commonly occurs with 2:1 or 3:1 AV block, so the ventricular response may be regular and typically at a rate of 150 bpm.
- AFib and AFlut are related arrhythmias, sometimes seen in the same patient. Distinguishing the two is important because there may be implications for management.
- Clinical classifications:
  - Paroxysmal: self-terminating episodes, usually <7 days
  - Persistent: sustained >7 days, usually requiring pharmacologic or DC cardioversion to restore sinus rhythm.
  - Permanent: Sinus rhythm cannot be restored or maintained.
  - Nonvalvular AFib: absence of moderate-to-severe mitral stenosis or a mechanical heart valve.
- Lone AFib occurs in patients <60 years (with possible genetic predisposition) who have no clinical or echocardiographic evidence of cardiovascular disease, including hypertension (HTN).

EPIDEMIOLOGY
- Incidence/prevalence increases significantly with age.
- Young patients with AFib, particularly lone AFib, are most commonly males.

Incidence
- AFib: from <0.1%/year <40 years to >1.5%/year >80 years
- Lifetime risk: 25% for those ≥40 years
- AFlut is less common.

Prevalence
- Estimated at 0.4–1% in general population, with 2.7 million patients in America
- Increases with age, up to 8% in those ≥80 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Cardiac: HTN, ischemic heart disease, heart failure, valvular heart disease, cardiomyopathy, pericarditis, and infiltrative heart disease
- Pulmonary: pulmonary embolism (PE), chronic obstructive pulmonary disease (COPD),
obstructive sleep apnea, pneumonia
- Ingestion: ethanol, caffeine
- Endocrine: hyperthyroidism, diabetes
- Obesity
- Postoperative: cardiac, pulmonary, or esophageal
- Idiopathic: lone AFib
- Patients with paroxysmal episodes are usually associated with premature atrial beats and/or bursts of tachycardia, originating in pulmonary vein ostia or other sites.
- Many patients with AFib are thought to have some degree of atrial fibrosis or scarring. This is often subclinical and usually not detectable with current cardiac imaging techniques but plays an important role in the pathogenesis of the arrhythmia.
- Autonomic (vagal and sympathetic) tone may play a role in triggering the arrhythmia.
- The presence of AFib is associated with electrical and structural remodeling processes that promote arrhythmia maintenance in the atria, termed “AFib begets AFib.”

**Genetics**
Familial forms are rare but do exist. There are ongoing efforts to identify the genetic underpinnings of such cases.

**RISK FACTORS**
Age, HTN, and obesity are the most important risk factors for both AFib and AFlut.

**GENERAL PREVENTION**
Adequate control of HTN may prevent development of AFib due to hypertensive heart disease and is the most significant modifiable risk factor for AFib. Weight reduction may decrease the risk of AFib in obese patients. Ethanol consumption may trigger AFib in some.

**COMMONLY ASSOCIATED CONDITIONS**
HTN and other cardiac diseases

**DIAGNOSIS**

**HISTORY**
Symptoms vary from none to mild (palpitations, light-headedness, fatigue, poor exercise capacity) to severe (angina, dyspnea, syncope).

**PHYSICAL EXAM**
- AFib: irregularly irregular heart rate and pulse, frequently tachycardiac, pulse deficit
- AFlut: similar to AFib but may have regular pulse

**DIFFERENTIAL DIAGNOSIS**
- Multifocal atrial tachycardia
- Sinus tachycardia with frequent atrial premature beats
- Paroxysmal supraventricular tachycardia (Wolff-Parkinson-White [WPW], atrioventricular nodal reentry tachycardia [AVNRT])

**DIAGNOSTIC TESTS & INTERPRETATION**
- Although screening with ECG can detect asymptomatic cases of AFib, the U.S. Preventive
Services Task Force notes that it has not been shown to detect more cases than screening focused on pulse palpation. Also, treatments for AFib reduce the risk of stroke and all-cause mortality and increase the risk of bleeding, but trials have not assessed whether treatment of screen-detected asymptomatic older adults results in better health outcomes than treatment after detection by usual care or after symptoms develop (1)[A].

- The ECG is diagnostic, with findings of low-amplitude fibrillatory waves without discrete P waves and an irregularly irregular pattern of QRS complexes. There is often tachycardia in the absence of heart rate–controlling medications.
- AFib: The ECG is diagnostic. Saw-tooth F waves are the classic sign, generally best seen in the inferior leads, although ventricular rate may need to be slowed to see the waves. QRS complexes may be regular or irregular; there is usually tachycardia.
- Ambulatory rhythm monitoring (e.g., telemetry, Holter monitoring, event recorders) is helpful in diagnosing suspected paroxysmal AFib or AFib and monitoring for recurrence.

**Initial Tests (lab, imaging)**

Thyroid-stimulating hormone, electrolytes, complete blood count, 2D transthoracic echocardiogram, prothrombin time/international normalized ratio (if anticoagulation is contemplated); digoxin level (if appropriate)

**Follow-Up Tests & Special Considerations**

- Occasional Holter monitoring and/or exercise stress testing to assess for adequacy of rate and/or rhythm control
- Chest x-ray (CXR) for cardiopulmonary disease
- ECG for signs of cardiac hypertrophy, ischemia, and/or other arrhythmias
- Transesophageal echocardiogram to detect left atrial appendage thrombus if cardioversion is planned
- Sleep study may be useful if sleep apnea is suspected.

**Test Interpretation**

Evaluate for presence of atrial dilatation and fibrosis, atrial thrombus (especially in atrial appendage), valvular/rheumatic disease, cardiomyopathy.

---

**TREATMENT**

**MEDICATION**

- Two primary issues in the management of AFib and/or AFib: decisions on heart rate control (control ventricular rate while allowing AFib to continue) or rhythm control (terminate AFib and restore normal sinus rhythm) and decision to anticoagulate or not.
- Anticoagulation therapy to prevent thromboembolism (primarily stroke) reduces risk of stroke by about 2/3. Several calculators exist for estimating yearly risk of thromboembolic event (ATRIA, CHA\textsubscript{2}DS\textsubscript{2}VASc). If risk is sufficiently low, or risk of bleeding is high, no anticoagulation may be indicated. Clinical judgment and patient preference remain important.
- American Heart Association/American College of Cardiology anticoagulation guidelines (the same for AFib and AFlut):
  - CHA\textsubscript{2}DS\textsubscript{2}VASc scoring (CHF [1 point], HTN [1 point], Age $\geq$75 years [2 points], DM [1 point], prior Stroke or transient ischemic attack [TIA] [2 points], Vascular disease [1 point],...
Age 65 to 74 years [1 point], female Sex category [1 point]). CHA\textsubscript{2}DS\textsubscript{2}VASc is the recommended stroke risk assessment for patients with nonvalvular AFib.

- In patients with nonvalvular AFib and a CHA\textsubscript{2}DS\textsubscript{2}VASc score of 0 in men or 1 in women, anticoagulant therapy may be omitted (2)[B].
- In patients with nonvalvular AFib and a CHA\textsubscript{2}DS\textsubscript{2}VASc score $\geq 1$ nonsex risk factors, oral anticoagulant therapy may be considered (2)[C]. Aspirin is no longer recommended for antithrombotic therapy in atrial fibrillation.

- Unless contraindicated, patients with nonvalvular AFib with any high-risk factors for stroke (prior TIA/cerebrovascular accident [CVA]/thromboembolism) or a CHA\textsubscript{2}DS\textsubscript{2}VASc score $\geq 2$ in men or $\geq 3$ in women should receive oral anticoagulants (2). DOAC (direct-acting oral anticoagulant)/NOAC (novel oral anticoagulant) agents are preferred for most patients with nonvalvular atrial fibrillation who should receive anticoagulant therapy. Oral anticoagulants include warfarin with maintenance of an international normalized ratio (INR) of 2.0 to 3.0, dabigatran, rivaroxaban, apixaban, or edoxaban (2)[B]. Patients with mechanical valves should be treated with warfarin to maintain an INR of 2.0 to 3.0 or 2.5 to 3.5 dependent on the type and location of the prosthesis.

- Recommendation to anticoagulate is independent of AFib pattern (paroxysmal, persistent, and permanent), although ongoing efforts to better understand who may be at greater and lesser risk of thromboembolism continue.

- Dabigatran (Pradaxa), apixaban (Eliquis), rivaroxaban (Xarelto), and edoxaban (Savaysa), a new factor Xa inhibitor are available DOAC/NOAC medications (2)[A]. The selection of an antithrombotic should be individualized; consider the risks of each agent, cost, patient preference, and tolerability.

**ALERT**
Renal and hepatic functions should be evaluated prior to initiation of direct thrombin or factor Xa inhibitors (2)[B]. Limited information is available about safety in patients on renal dialysis. Dosing of such agents may in fact need individualized adjustment. Specific reversal agents for life-threatening bleeding are available:

- Reversal agents are available for some DOAC/NOAC medications:
  - Idarucizumab (Praxbind) for dabigatran (2)[B]
  - Coagulation factor Xa (recombinant), inactivated-zhzo (Andexxa) for apixaban and rivaroxaban (2)[B]

In addition to anticoagulation, initial rate control must be achieved followed by a decision regarding long-term strategy: rate-control alone, or rhythm control. Four classes of medications are available to achieve ventricular rate control: β-blockers (i.e., metoprolol), nondihydropyridine calcium channel blockers (i.e., verapamil, diltiazem), digoxin, and amiodarone. Optimal target for ventricular rate has not been firmly established, but there is evidence that aggressive control of the ventricular rate ($< 80$ bpm) offers no benefit beyond more modest rate control (i.e., resting heart rate $< 110$ bpm).

- Preventing rapid ventricular response (RVR) rates using AV nodal blocking medications is also often effective at controlling a patient’s symptoms associated with AFib or AFib. Patients in whom rate control cannot be achieved or who continue to have persistent symptoms despite reasonable heart rate control may require attempts at restoration of sinus rhythm.

- Ventricular rate control can often be difficult to achieve in AFib due to the more organized
nature of the atrial electrical activity. For this reason, conversion to sinus rhythm is often the preferred strategy for symptomatic patients, and catheter ablation is also considered as a first-line treatment in recurrent AFLut.

- Restoration of sinus rhythm using electrical or pharmacologic cardioversion may significantly reduce the symptom burden of AFib or AFLut in many patients and may also be useful for controlling ventricular rate. Cardioversion does not impact the long-term risk/benefit ratio of anticoagulation:
  - Cardioversion is most often performed electrically, but may also be achieved using antiarrhythmic drug therapy in some instances, by experienced clinicians.
  - If duration of AFib/AFLut is ≥48 hours or unknown, anticoagulate for ≥3 weeks before cardioversion to reduce the risk of stroke. Alternatively, once anticoagulation is established, a transesophageal echo may be performed to exclude the presence of left atrial thrombus, allowing cardioversion to proceed. After cardioversion, anticoagulation should be continued for ≥4 weeks in all patients in whom duration of AFib/AFLut is >48 hours, as the postcardioversion period is a time of increased stroke risk regardless of the CHA2DS2-VASc score or the method used to restore sinus rhythm (2)[B].
- Randomized clinical trials (AFFIRM and RACE) comparing the outcomes of rate versus rhythm control found no difference in morbidity, mortality, and stroke rates in patients assigned to one therapy or the other.

 ISSUES FOR REFERRAL
Management of AFib or AFLut refractory to standard medical therapy (i.e., unable to achieve adequate rate control with medication or development of significant bradycardia with treatment) may require the use of more aggressive treatments. These may include pacemaker implantation (to allow for more intensive pharmacologic blocking of the AV node) or an ablation procedure. AFLut in particular is often very amenable to ablation; thus, consideration should be given to early expert referral in appropriate patients. Antiarrhythmic drug therapy can often be very effective but should be prescribed by experienced practitioners.

 SURGERY/OTHER PROCEDURES
- Electrophysiologic study and ablation may be considered for patients with either AFib or AFLut. In the case of AFLut, ablation is a procedure viewed as a first-line therapy due ablation of AFib may be reasonable in symptomatic patients with heart failure with reduced ejection fraction (HFrEF) to lower mortality and reduce hospitalization (2)[B].
- Cardiac surgery (e.g., the maze procedure, ligation of the left atrial appendage) may be considered in patients planning to undergo cardiac surgery for other reasons.
- A left atrial appendage closure device WATCHMAN may be useful in those at increased risk of stroke and systemic embolism who have contraindications to long-term anticoagulation (2)[B].

 ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Patients with significant symptoms, RVR, AFib/AFLut triggered by an acute process (e.g., MI, CHF, PE), or in whom antiarrhythmic therapy is being started likely require admission to the hospital for a period of stabilization.
- Outpatient management is reasonable for low-risk patients with controlled ventricular rates.
- Acute therapy for symptomatic patients with AFib or AFLut:
  - IV β- or nondihydropyridine calcium channel blockers for control of ventricular rate in
patients without preexcitation

- Commonly used therapies in the acute setting include:
  - Metoprolol tartrate: 2.5 to 5.0 mg IV bolus over 2 minutes; up to 3 doses
  - Diltiazem: 0.25 mg/kg IV bolus over 2 minutes and then 5 to 15 mg/hr
  - Some patients will be far more responsive to one class of agents than another. For this reason, if rate control is difficult to achieve, switching drug classes may be useful.

- Urgent cardioversion should be performed in hemodynamically unstable patients. It is somewhat unusual for AFib or AFlut alone to cause marked hemodynamic insult; thus, the possibility of a concurrent process should be considered in this setting.

- Consider the initiation of PO anticoagulation therapy.

**ONGOING CARE**

Consider elective expert consultation

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Adequate anticoagulation levels with warfarin should be determined weekly during initiation and monthly when stable. If NOACs are employed, hepatic and renal functions should be reevaluated annually (2)[B].

**DIET**

Patients on warfarin should attempt to consume a stable amount of vitamin K.

**PATIENT EDUCATION**

For overweight and obese patients, weight loss combined with risk factor modification have demonstrated beneficial effects on controlling AFib (2)[B].

**PROGNOSIS**

Yearly risk of stroke in untreated nonvalvular AFib has declined and now lies between 4% and 5% per year.

- Anticoagulation reduces the annual embolic stroke rate by about 2/3 for most patients. AFib and AFlut may increase morbidity and mortality, but the overall prognosis is a function of underlying heart disease and adherence with therapy. Reported risk of anticoagulation varies but lies between 1% and 4% per year for major hemorrhage.

**COMPLICATIONS**

- Embolic stroke
- Peripheral arterial embolization
- Bleeding with anticoagulation
- Tachycardia-induced cardiomyopathy with prolonged periods of inadequate rate control

**REFERENCES**

CODES

ICD10
- I48.91 Unspecified atrial fibrillation
- I48.92 Unspecified atrial flutter
- I48.0 Paroxysmal atrial fibrillation

CLINICAL PEARLS
- Younger patients do better with a rhythm control strategy, older patients often do well with rate control.
- Whether to anticoagulate or not is based on risk of thromboembolism regardless of AFib pattern.
- Reevaluation of the need for and choice of anticoagulation therapy at periodic intervals is recommended to reassess stroke and bleeding risks.
BASICS

DESCRIPTION

- **Anatomy**
  - Opening in the atrial septum allowing flow of blood between the two atria
  - Patent foramen ovale is also an open communication between the atria, but it is not considered an atrial septal defect (ASD) because no septal tissue is missing.

- **Types (by location in the interatrial septum)** (1)
  - Classified based on their different anatomic location and abnormal embryogenesis:
    - secundum ASD, primum ASD, sinus venosus ASD, coronary sinus ASD
  - 70%: Ostium secundum defect occurs in the fossa ovalis region.
  - 15–20%: Ostium primum defect occurs in the inferior septum; often associated with cleft mitral valve and failure of endocardial cushion development
  - 5–10%: Sinus venosus defect occurs in the superior-posterior septum near the orifice of the superior vena cava; usually associated with partial anomalous right upper pulmonary venous return
  - Less than 1%: coronary sinus defect: Part of the entire common wall between the coronary sinus and the LA is absent.

- **Hemodynamic effects**
  - Left-to-right shunting in late ventricular systole and early diastole
  - Degree depends on size of the defect and relative pressures of the two ventricles.
  - Causes excessive blood flow through the right-sided circulation, ultimately leading to reactive pulmonary hypertension and heart failure

- **Systems affected:** cardiovascular; pulmonary

**Pediatric Considerations**

- Most cases of ASD are detected and corrected in the pediatric population.
- The smaller the defect and the younger the child, the greater the chance of spontaneous closure.

**EPIDEMIOLOGY**

**Incidence**

- Predominant age: present from birth, may be diagnosed at any age
- Slight female predominance (2)
- No race predilection
- 2/1,000 live births

**Prevalence**

ASDs account for 13% of congenital heart disorders.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Flow across ASD usually left-to-right shunt because of higher left-sided pressures:
  - Minimal right-to-left shunting in early ventricular systole, especially during inspiration
– Increased right-sided pressure/pulmonary hypertension can cause reversal of shunt flow (Eisenmenger syndrome) with resulting cyanosis and clubbing.

• Symptoms typically occur due to right ventricular and pulmonary vascular volume overload and right-sided heart failure.

GENETICS
• Most cases are spontaneous.
• 5% with chromosomal abnormalities; other rare mutations exist.
• 25% prevalence in Down syndrome

RISK FACTORS
• Other congenital heart defects
• Family history (~7–10% recurrence)
• Thalidomide, alcohol exposure in utero, smoking, maternal age >35 years, and elevated blood glucose have been associated with increased risk (2).

COMMONLY ASSOCIATED CONDITIONS
• ASDs may occur as a component of other complex cardiac structural defects.
• Important to exclude anomalous pulmonary venous return
• Occasionally can indicate underlying genetic syndromes, for example, Holt-Oram (ASD present in 66%), Ellis-van Creveld, VACTERL syndrome, or Noonan syndrome.
• Overall, ~70% isolated (1)

DIAGNOSIS

HISTORY
• Most ASDs are small and do not cause symptoms in infancy and childhood and are often found on routine physical examination when a cardiac murmur is detected incidentally.
• Infants with large ASDs may present with right-sided heart failure (more advanced, only 10% at diagnosis), recurrent respiratory infections, or failure to thrive.
• Should be considered in children with other congenital heart defects, Down syndrome
• In uncorrected defects, most people become symptomatic by age 40 years. Common symptoms in adults include atrial arrhythmias (the most frequent presenting symptom), exercise intolerance, dyspnea, and fatigue.

PHYSICAL EXAM
• Signs vary according to extent of shunting.
• Cardiac auscultation
  – Fixed, widely split S2 (key physical finding)
  – May also have
    o Systolic ejection murmur (pulmonic flow murmur)
    o Low-pitched diastolic rumble (tricuspid flow murmur)
    o Diastolic murmur (pulmonic regurgitation)
    o Systolic murmur (mitral regurgitation)
• Right ventricular heave
• Palpable pulmonary artery pulse at left upper sternal border
• If heart failure has developed, may hear a fourth heart sound (right-sided)
• Signs of Eisenmenger syndrome:
  – Cyanosis and clubbing
  – Jugular venous distention and edema

DIFFERENTIAL DIAGNOSIS
• Other congenital heart disease
• Right bundle branch block (for widely split S₂)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
• Echocardiography is the test of choice (1)[C].
  Generally start with transthoracic Doppler imaging of the entire atrial septum (sensitivity is
  ~89% for secundum, ~100% for primum, and ~44% of sinus venosus ASDs), with progression
  to transesophageal echocardiography (TEE) if transthoracic echocardiography (TTE) is
  nondiagnostic.
• Patients with right ventricular overload by TTE but an otherwise negative study should have
  further testing.
• Oximetry: Cyanosis may suggest Eisenmenger syndrome (right-to-left shunting).
• ECG is not typically diagnostic, but findings may include the following:
  – Right axis deviation
  – Right atrial enlargement (tall P in inferior leads)
  – Right ventricular conduction delay
  – Q wave in lead V₁
  – Right bundle branch block
  – Leftward axis, inverted P wave in lead III (sinus venosus)
  – Leftward axis (ostium primum)

Follow-Up Tests & Special Considerations
• Bubble contrast enhancement may be helpful.
• TEE may be required to define ASD morphology and to locate the pulmonary veins; often
  used prior to percutaneous closure. TEE has excellent sensitivity and specificity.

Diagnostic Procedures/Other
• Cardiac catheterization (1)[C]
  – Demonstrates right ventricle enlargement, location/fraction of the shunt, size of the ASD,
    any valvular disease, and overall anatomy
  – Used to assess pulmonary vascular resistance if pulmonary hypertension is suspected,
    particularly if surgery is planned
  – Generally not used in young patients for initial diagnosis, more often reserved for use when
    o Part of a planned interventional closure
    o Evaluating other disease simultaneously (e.g., coronary artery disease)
    o Visualization by other methods insufficient
• Cardiac magnetic resonance: a noninvasive follow-up to echo that allows viewing the
  defect/pulmonary veins and measurement of shunt fraction and right ventricular function—
  particularly useful for sinus venosus defects (2)
• Exercise testing: useful to quantify symptoms not consistent with clinical findings or to
document change over time (1)[C]
Chest x-ray: may demonstrate right ventricular and pulmonary artery enlargement, increased pulmonary vascular markings
Cardiac CT scans can also define ASDs but with significant radiation exposure.

TREATMENT

GENERAL MEASURES
- 75% of small secundum ASDs (<8 mm) will close spontaneously by 18 months of age; however, close follow-up is warranted (2).
- The likelihood of spontaneous closure is mainly determined by defect diameter: >10 mm at time of diagnosis is unlikely to spontaneously close (3).
- Primum and sinus venosus defects do not generally close and generally require surgical closure (2).

MEDICATION

First Line
- Treatment of secondary atrial fibrillation/supraventricular tachycardia with anticoagulation and cardioversion, followed by anticoagulation with maintenance of sinus rhythm if possible, or rate control if this fails (1)[A]
- Pulmonary vasodilator therapy may be considered for adults with progressive/severe pulmonary vascular disease (1)[B].
- Treatment of heart failure (diuretics, oxygen, digoxin, etc.)

Second Line
- Antibiotic prophylaxis is NOT recommended for unrepaired/isolated ASDs.
- The American Heart Association (AHA) recommends antibiotic prophylaxis against infective endocarditis during dental procedures for 6 months after the repair in patients whom a device or prosthetic material is used.
  - In patients with repaired ASD who have a residual defect at or adjacent to the device, prophylaxis is recommended indefinitely.
  - If prophylaxis is indicated, for dental procedures, amoxicillin 2 g (adults) or 50 mg/kg (children). Other options include cephalosporins (e.g., ceftriaxone 1 g [adults] or 50 mg/kg [children] IM or IV) or clindamycin 600 mg PO (adults) or 20 mg/kg PO (children) or azithromycin 500 mg PO (adults) or 15 mg/kg (children) in patients who are penicillin-sensitive (4)[B].
- To prevent thrombus formation after device deployment, aspirin alone or a combination of aspirin and clopidogrel 75 mg for at least 6 months is recommended (5).

SURGERY/OTHER PROCEDURES
- The majority of small secundum defects, <6 mm, close spontaneously by 2 years of age, and some as late as 5 years. Closure is generally indicated in children with:
  - Defect >8 mm (unlikely to close) in children >2 years of age (to allow time for spontaneous closure, even though uncommon)
  - Defects of any size in a child >5 years with related symptoms
- Closure for secundum defects is not recommended in asymptomatic patients before 2 years of age given the possibility of spontaneous closure.
In adults, secundum closure via percutaneous transcatheter device or surgery to reduce subsequent morbidity and mortality, if:

- Right-side heart enlargement regardless of symptoms (1)[B]
- Pulmonary systemic flow ratio is 2:1 (or >1.5:1 and <21 years old according to the AHA).
- Symptoms such as documented orthodeoxia/platypnea or paradoxical embolism (1)[C]

Surgical repair is standard for a sinus venosus, coronary sinus, or primum ASD (1)[B],(2)[B]. These defects rarely close spontaneously and are not considered amenable to percutaneous closure.

Percutaneous closure is considered the treatment of choice of secundum ASD in adults (6)[A]. It is safe and effective with satisfactory long-term clinical follow-up. In addition, the use of closure device does not significantly affect aortic or mitral valve function (6)[B].

Secundum ASDs that are suitable for percutaneous closure should be ~35 mm in stretched balloon diameter and should have a sufficient rim of surrounding atrial tissue.

Closure is not indicated for patients who have developed irreversible severe pulmonary hypertension without continued shunting or those who never develop symptoms and have an ASD <5 mm (1)[B].

Overall, closing small asymptomatic secundum ASDs is controversial and not often done.

Maze procedure may be considered before or after closure for patients with intermittent or chronic atrial tachyarrhythmias (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Echocardiography can be used to monitor both repaired and unrepaired ASDs.

**Patient Monitoring**

- In otherwise asymptomatic healthy children, follow up until defect has closed or become negligible in size.
- Appropriate evaluation and management for atrial tachyarrhythmias in patients with long-term follow-up (1)[C]
- If ASD repaired as an adult, periodic long-term follow-up is indicated (1)[C].
- ASDs repaired in childhood generally do not have late complications.
- In female patients with unrepaired ASD and Eisenmenger syndrome, pregnancy is not recommended due to increased risk of maternal and fetal mortality (1)[C].
- Pregnancy is well tolerated in patients with repaired ASD and small unrepaired ASDs (1)[A].
- Scuba diving and high-altitude travel must be approached with caution in patients with unrepaired ASDs; consultation is recommended.

**PATIENT EDUCATION**

For patient education materials on this topic, consult the following:

- American Heart Association: [https://www.heart.org](https://www.heart.org)

**PROGNOSIS**

- ASD closure in asymptomatic or minimally symptomatic adults reduces morbidity but not
mortality (7).
• ASD closure before age 25 years in symptomatic adults reduces morbidity and likely also mortality.
• ASD repair deferred until after adolescence may not decrease long-term risk of future atrial arrhythmias.
• Up to 50% mortality by age 50 years in untreated symptomatic patients with large defects

COMPLICATIONS
• Unrepaired: congestive heart failure, stroke, pulmonary hypertension/Eisenmenger syndrome, atrial arrhythmias, increased infection risk (pulmonary, cerebral abscess, infective endocarditis)
• Surgically repaired: late-onset arrhythmias 10 to 20 years after surgery (5%), perioperative atrial tachyarrhythmias in 10–13% of patients
• Device closure: device embolization (1%), cardiac perforation, thrombus formation, endocarditis, supraventricular arrhythmias, and device erosions

REFERENCES

SEE ALSO

CODES

ICD10
- Q21.1 Atrial septal defect
- Q21.2 Atrioventricular septal defect

CLINICAL PEARLS
- ASD is often missed due to subtle clinical presentation.
- Ideally, hemodynamically significant ASDs should be closed in early childhood, although some benefit from closure is present in older patients.
- Many ASDs can be treated by catheter-directed percutaneous closure rather than open-heart surgery.
- Routine endocarditis prophylaxis is not recommended for unrepaired ASDs.
- Generally, symptomatic and hemodynamically significant ASDs are repaired; management of asymptomatic small ASDs is debated.
- Patent foramina ovalia, unlike large ASDs, are very common and generally require no treatment in asymptomatic individuals.
Adult attention deficit hyperactivity disorder (adult ADHD) is a psychiatric condition resulting in inattention and/or hyperactivity or impulsivity. It is typically associated with a combination of low self-esteem, dysfunctional or unstable social relationships, and impaired academic/job performance.

Adult ADHD has been shown to affect a significant portion of the adult population; 30–60% of patients diagnosed with ADHD as a child will continue to meet criteria as adults.

During transition from pediatric to adult care, poor control of high-risk behaviors during a hiatus of ADHD treatment can lead to increased morbidity.

Symptoms include difficulty concentrating, impulsivity, and hyperactivity/overactivity. Impairment in executive functioning and emotional dysregulation are common features.

The three main types of ADHD are (i) hyperactivity-impulsivity predominant, (ii) inattentive predominant, and (iii) combined.

ADHD affects approximately 4.4–5.2% of adults between 18 and 44 years of age (1).

ADHD has a strong genetic component, with heritability of approximately 0.8, suggesting that genetic factors would account for about 65% of phenotypic variance (2).

Studies have shown that the risk of ADHD is increased among offsprings of mothers who smoked or had obesity and diabetes during pregnancy. Risk is also increased in those who had lead exposure in childhood. It is unknown whether these associations are causal (2).

Premature birth; very low birth weight; and extreme neglect, abuse, or social deprivation also increase the risk as do certain infections during pregnancy, at birth, and in early childhood.

ADHD is more commonly diagnosed among adult males than females, with an odds ratio of 1.6:1.0 (1); however, some studies have shown that this is due to the less overt symptoms in females.

Substance use and substance abuse disorders
Mood disorders
Anxiety disorders
Intellectual disabilities
Obsessive-compulsive disorder (OCD)
Tic disorders
DIAGNOSIS

- Diagnosis is made from patient’s history and detailing patient’s current level of functioning in at least two different settings (e.g., work and home).
- It is important to gather history of patient’s childhood and school performance. Several inattentive or hyperactive-impulsive symptoms should be present prior to age 12 years.

HISTORY

- History of childhood ADHD symptoms before age 12 years
- DSM-5 criteria for adults ≥17 years include ≥5 hyperactivity/impulsivity symptoms and/or ≥5 inattentive symptoms. These symptoms must be present for ≥6 months (1).
- Symptoms must result in maladaptive behavior that impairs the patient’s function.
- There must be clear evidence of impaired function due to inattention/hyperactivity in ≥2 settings (e.g., home and work).
- These symptoms must not be related to a psychotic episode or mood disorder and must not be better explained by another DSM diagnosis. However, DSM-5 allows a comorbid diagnosis with autism spectrum disorder.
- Reports of symptoms from adult patients are likely to be less accurate than reports from others. Specifically, symptoms regarding problems with employment (e.g., job dismissal), domestic life (e.g., strained relationships with one’s spouse and children), and social activities (e.g., friendship breakups). Therefore, the DSM-5 recommends obtaining history from a friend or family member with long-term knowledge of the patient (2).
- Personal and family history of cardiac disease or sudden death should be documented.
- History of exposure to lead or other toxins
- History of thyroid disease
- History of medication or substances including anticonvulsants, steroids, antihistamines, nicotine, and caffeine that have side effects that impact attentiveness and mimic ADHD symptoms

PHYSICAL EXAM

- Physical exam is key to ruling out other medical conditions.
- Focus on thyroid and neurologic examinations; look for findings suggestive of substance abuse.
- Record BP and baseline weight; monitor if starting medical treatment.

DIFFERENTIAL DIAGNOSIS

Hearing impairment; hyperthyroid/hypothyroid; sleep deprivation; sleep apnea; phenylketonuria; OCD; lead toxicity; substance abuse (3)[A]

DIAGNOSTIC TESTS & INTERPRETATION

- Adult ADHD screening tools: Retrospective scales include the Childhood Symptom Scale and the Wender Utah Rating Scale; current symptom scales include the Adult ADHD Rating Scale IV, Adult Self Report Scale Symptom Checklist, and the Connor Adult Rating Scale(1). These scales can take 5 to 20 minutes to complete.
- Provider/patient screening checklist
  - https://med.nyu.edu/psych/sites/default/files/psych/psych_adhd_screener_0.pdf
Developments in imaging techniques have revealed structural and functional brain differences between individuals with and without ADHD, but there is no evidence for clinical utility (1).

**Initial Tests (lab, imaging)**
- Thyroid-stimulating hormone (TSH)
- Rapid plasma reagin (RPR) or venereal disease research laboratory (VDRL) test
- ECG with concerns for cardiac disease in patient or family history
- Serum lead levels (pending history)

**Follow-Up Tests & Special Considerations**
- Liver function test monitoring (with atomoxetine)
- A history of childhood behaviors is helpful, but adult patients often don’t accurately recall childhood symptomology.
- Inquire about family history of ADHD, family and personal substance abuse, and tic disorders to facilitate formulation of an accurate diagnosis and recognition of high-risk behaviors.
- Caution against stimulant use in pregnancy because of high risk of low fetal birth weight and preterm birth. Risks and benefits of treatment must be discussed in detail with patient and preferably with her spouse (4)[B].
- Caution against use of stimulants in adult patients with cardiac history.

**ALERT**
Mood disorders, generalized anxiety disorders, and substance abuse can also coexist with adult ADHD; treating both the ADHD and comorbid conditions will improve the patient’s prognosis.

**TREATMENT**
- Most of the research and medication trials have been performed in children.
- There is increasing evidence that stimulants and nonstimulants used in children are also effective in adults (3)[A].

**ALERT**
Because stimulant medication may induce dependency, substance abuse, and diversion, it is necessary to do pill counts, screen urine for drugs, monitor behavior, and query prescription databases. Misuse of amphetamines may cause sudden death and serious cardiovascular adverse events.

**GENERAL MEASURES**
When substance abuse is not present, stimulants are first-line treatment for ADHD and highly efficacious. There are multiple formulations of stimulants, and patients may require trials of different dosages, formulations, and medications before an optimal response in symptoms and functions is achieved. Non-stimulants are useful when there is abuse potential, comorbid conditions, or poor response to stimulants.

**MEDICATION**
- Psychotropic medications play a large part in the treatment of ADHD symptoms. Medications should be titrated slowly to effective dose to avoid side effects.
- Stimulants are more effective than antidepressants or nonstimulants, but up to 30% discontinue medications because of side effects.
Stimulants can be grouped into those related to methylphenidate and those related to amphetamine. Both groups include both short- and long-acting preparations. Recent evidence suggests that adherence and persistence rates improve in those using long-acting agents (1).

Antidepressants studied for ADHD include bupropion, which has been shown to have a medium effect compared with stimulants (3)[A].

First Line

Stimulants: methylphenidate (Concerta, Ritalin), dexamethylphenidate (Focalin), dextroamphetamine/amphetamine (Adderall), dextroamphetamine (Dexedrine), lisdexamfetamine (Vyvanse)
- Methylphenidate preparations are available in short acting, intermediate acting, long acting, and patch formulations.
- Ritalin LA may be used for patients naive to stimulants. It can be started at 20 mg daily and dose titrated by 10 mg increments weekly to symptoms response; max dose of 60 mg/day
- Concerta ER is another option in adults up to 65 years of age. Starting dose of 18 mg/day; adjust in increments of 18 mg weekly until symptoms improve. Max dose 72 mg/day; also has an oral osmotic release to decrease abuse potential
- Amphetamines also come in immediate-release preparations and sustained-release preparations.
- Dextroamphetamine is commonly used (half-life of 4 to 6 hours) with an initial dose of 5 mg BID; titrate up by 5 mg weekly to maximum of 20 mg BID.
- Dextroamphetamine/amphetamine (Adderall) is a 75%/25% mix that also comes in an extended-release form. Initial dosing can be started at 5 mg BID for short acting or 20 mg daily for long acting and increased by 5 mg/week for short acting and 10 mg/week long acting to a maximum of 40 to 60 mg total daily.
- Lisdexamfetamine (Vyvanse) is an extended-release stimulant that is a prodrug requiring metabolization to active component, dextroamphetamine.
- Common side effects of stimulants include hypertension (HTN), tachycardia, insomnia, weight loss, stomach upset, increased anxiety/irritability, or worsening of tics (3)[A].

Nonstimulants:
- Atomoxetine (Strattera) has been shown effective in adults with ADHD when compared to placebo (5)[B]. It may be given as a single dose or split dose and has low abuse potential, making it a better choice over a stimulant medication for patients with substance abuse history. Onset of effect may take up to 4 weeks. Atomoxetine may be particularly useful when anxiety, mood or tics co-occur with ADHD. Also, there are rare cases of liver damage associated with these medications. Monitor for increased suicidal thinking.
- Antidepressants: best used for those at high risk or with history of substance abuse disorder. Bupropion (Wellbutrin) is an antidepressant effective in adults with ADHD symptoms, especially if they have comorbid depression (4)[A].
- Tricyclic antidepressants (desipramine and nortriptyline) have also shown to be effective in ADHD (1).
- α2-Agonists (guanfacine, clonidine) have been found to be effective in children and adolescents; however, their efficacy, safety, and tolerability have not been studied extensively in adults (6)[C]. These may be used with comorbid tics and/or disruptive behavior disorders.
- Combining stimulants with a nonstimulant medication such as atomoxetine, guanfacine, or clonidine has shown positive effects among patients who are resistant to stimulants alone.
ISSUES FOR REFERRAL
Patients with comorbid conditions may need referral for diagnosis and treatment. Consider cardiology consult for patients with known cardiac issues who may require stimulant treatment. Consider referral to obstetrician experienced in high-risk pregnancies when treating pregnant women with ADHD.

ADDITIONAL THERAPIES
- Cognitive-behavioral therapy (CBT) can be useful in conjunction with medication to help patient modify and cope with symptoms. CBT helps reduce impairments resulting from executive dysfunction (EDF) that is not optimally ameliorated with medication (1).
- Among adults with ADHD and EDFs, addition of memantine as an adjunct to extended release methylphenidate was associated with improved executive functioning, supporting the need for further research.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Vitamin–mineral supplementation is an area of active research that holds promise for improved ADHD treatment.

ONGOING CARE
Transfer from pediatric to adult care must be closely coordinated to avoid hiatus in treatment.
- Support groups (e.g., www.chadd.org and www.add.org) assist the newly diagnosed adult by providing education, treatment options, available resources, and peer support.

FOLLOW-UP RECOMMENDATIONS
- Close follow-up of medication as dose is titrated
- Continue to monitor for medication side effects.
- Repeat screening checklists to quantify benefit of interventions as needed.
- Reinforce behavioral change (e.g., self-initiated through CBT), which is essential goal of long-term management.

ADDITIONAL READING

CODES

ICD10

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type

CLINICAL PEARLS

- Adult ADHD results in inattention, easy distractibility, hyperactivity, and impulsive behavior; it is associated with low self-esteem, problematic interpersonal relationships, and difficulty meeting academic and job expectations.
- Psychotropic medications plus cognitive behavioral treatments are the cornerstone of management.
- Substance abuse is a common comorbidity; recommend use of nonstimulant medication in those at high risk
ATTENTION DEFICIT/HYPERACTIVITY DISORDER, PEDIATRIC
Laura Novak, MD ● Katherine Williams, MD

BASICS

DESCRIPTION
- Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder that manifests in early childhood characterized by distractibility, impulsivity, hyperactivity, and/or inattention.
- Three subsets: predominantly hyperactivity impulsive (ADHD-HI), predominantly inattentive (ADHD-I), or combined (ADHD-C)
- System(s) affected: nervous
- Synonym(s): attention deficit disorder; hyperactivity

EPIDEMIOLOGY
- Predominant age: onset <12 years; lasts into adolescence and adulthood
- Predominant sex: male > female (2:1); ADHD-I is more common in girls.

Prevalence
5–11% of children 4 to 17 years

ETIOLOGY AND PATHOPHYSIOLOGY
Not definitive

Genetics
Familial pattern

RISK FACTORS
- Family history
- Medical causes (affecting brain development)

COMMONLY ASSOCIATED CONDITIONS
- Depression
- Oppositional defiant disorder
- Conduct disorder
- Anxiety disorder
- Learning disabilities

DIAGNOSIS
- American Academy of Pediatrics (AAP) guidelines recommend Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) criteria to establish diagnosis (1)[C].
- DSM-5 criteria for children <17 years: ≥6 inattention criteria and/or ≥6 hyperactivity/impulsivity criteria. Symptoms must occur often, be present before age of 12 years, for >6 months, be noticed in ≥2 settings (e.g., home, school), reduced quality of social
or scholastic functioning, be excessive for development level of child, and are not better explained by or occur with another mental disorder (e.g., depression, anxiety, or personality disorder) (2)[C].

- Inattention
  - Careless mistakes in tasks
  - Difficulty sustaining attention or in organizing
  - Does not seem to listen
  - Does not follow through or finish tasks
  - Avoids tasks that require sustained mental effort
  - Loses things
  - Forgetful in daily activities
  - Distracted by external stimuli
  - Forgetful

- Hyperactivity/impulsivity
  - Fidgets
  - Difficulty remaining seated
  - Runs/climbs excessively or inappropriately; difficulty playing quietly
  - Acts as if “driven by a motor” or seeming to always be “on the go”
  - Talks excessively
  - Blurs out answers before question is complete
  - Has difficulty waiting turn
  - Interrupts others

- Children undergoing extreme stress (divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress (1)[C]. This can be assessed using the American Academy of Child and Adolescent Psychiatry (AACAP) screening tool.

- If diagnostic behaviors are noted in only one setting, explore the stressors in that setting.
- The diagnostic behaviors are more noticeable in tasks that require concentration or boredom tolerance.

**HISTORY**

- Birth and development history
- Psychosocial evaluation of home environment
- School performance and school absences
- Psychiatric history or history of comorbid disorder(s)
- Cardiac history

**PHYSICAL EXAM**

- Baseline weight for future monitoring
- Note any soft neurologic signs, such as tics, clumsiness, mixed handedness.
- Assess hearing and vision.

**DIFFERENTIAL DIAGNOSIS**

- Activity level appropriate for age
- Dysfunctional family situation
- Learning disability (e.g., dyslexia)
- Hearing/vision/language disorder
- Autism spectrum disorders
- Oppositional/defiant disorder or conduct disorder
- Tourette syndrome: motor and verbal tics
- Absence seizures (ADHD-I only)
- Lead poisoning
- Sequelae of central nervous system infection/trauma
- Medication
- Sleep disorder

**DIAGNOSTIC TESTS & INTERPRETATION**
- Behavior rating scales completed by parents, caregivers, and teachers prior to initiation of therapy and then repeated after therapy
- Forms are available from the ADHD toolkit at [http://www.nichq.org/adhd.html](http://www.nichq.org/adhd.html) (Vanderbilt Assessment Scales).
- Testing for learning disability through the school

**Initial Tests (lab, imaging)**
Rarely needed. Consider lead.

**Diagnostic Procedures/Other**
Electrocardiogram (ECG) prior to stating stimulant medication if positive family history of premature cardiovascular disease

---

**TREATMENT**

**GENERAL MEASURES**
- Identify treatment goals based on behaviors that are most harmful to the child’s development.
- Coordinate school and home behavioral plan.
- Behavioral health consult; behavioral counseling can be beneficial for both parents and child, including parent training, academic training, and social training.
- Behavioral modifications should involve repeated positive reinforcement with limiting negative comments, reward systems (i.e., star charts for younger children, privileges for older children), environmental changes at both home and school (time out, quiet time), token economy (reward for positive, loss of reward for negative behavior)
- Children age 4–5 years should begin with behavioral interventions (2)[C].
- Age 6–17 years, begin with behavioral interventions (2)[C] and consider medication if behavioral goals are not being met over time
- Work closely with teacher and school.

**MEDICATION**
- Stimulant medication is often considered first line as they have highest efficacy, but also carry greater risks.
- Atomoxetine may be used first line, especially if there is risk of diversion in the home, growth concerns (poor weight gain, sleep issues, etc.), or if parents wish to try medication with less concerns
- Stimulant choice should be based on cost, formulary, convenience, and duration. A second type of stimulant should be tried if the first treatment fails (2)[C].
- All stimulant capsules can be opened and sprinkled (Note: Concerta is a pill).
**First Line**

**Stimulant:**
- **Methylphenidate**
  - Short acting—duration of action (DOA) 2 to 4 hours
    - Ritalin, Methylin: initial 2.5 mg BID before breakfast and lunch; increase by 5 mg q7d to max dose of 60 mg/day (divided BID/TID).
  - Intermediate acting—DOA 3 to 8 hours
    - Ritalin XR: 20 mg once in am; increase by 10 mg weekly up to max dose of 40 to 60 mg.
    - Metadate ER: 10 mg BID; increase by 10 mg weekly to max dose of 40 to 60 mg.
  - Long acting—DOA 8 to 12 hours
    - Metadate CD: 20 mg in am; increase by 10 to 20 mg weekly to max dose of 40 to 60 mg.
    - Quillivant XR: 20 mg in am; increase 10 to 20 mg weekly to max dose of 40 to 60 mg.
    - Ritalin LA: 10 to 20 mg in am; increase 10 mg weekly to max dose of 40 to 60 mg.
    - Concerta: 18 to 36 mg in am; increase by 18 mg weekly to max dose of 54 to 72 mg.
    - Daytrana transdermal patch: 10-mg patch on (hip area) 2 hours before effect is needed; patch removed 9 hours after application; increase to next higher patch weekly until max dose 30-mg patch.
- **Dexmethylphenidate**
  - Focalin: DOA 4 to 6 hours; initial: 2.5 mg BID; increase by 2.5 mg weekly up to max dose of 20 mg/day.
  - Focalin XR: DOA 12 hours; initial: 5 mg in am; increase by 5 mg weekly up to max dose of 30 mg/day.
- **Dextroamphetamine SR** DOA 8 to 12 hours
  - 5 mg BID; increase by 5 mg weekly to max dose of 40 mg daily.
- **Dextroamphetamine/amphetamine mixed salts**
  - Short acting—DOA 4 to 5 hours
    - Adderall: 2.5 mg daily or BID; increase by 5 mg weekly to a max divided dose of 40 mg daily.
  - Long acting—DOA 10 to 12 hours
    - Adderall XR: 5 mg in am; increase by 5 mg weekly until max dose of 30 mg/day.
- **Lisdexamfetamine (prodrug)**—DOA 10 to 12 hours
  - Vyvanse: 30 mg in am; increase by 10 mg weekly up to a max dose of 70 mg/day.

**ALERT**

Screen by history +/- ECG for cardiac disease before starting stimulant medication (2)[C].

- **Precautions:**
  - If not responding, check compliance and consider another diagnosis.
  - Some children experience withdrawal (tearfulness, agitation) after a missed dose or when medication wears off. A small, short-acting dose at 4 pm may help to prevent this.
  - Stimulants are drugs of abuse and should be monitored carefully.
  - Drug holidays are not recommended but may be tried in weight loss or ADHD-I.
- **Common adverse effects:**
  - Anorexia, insomnia, growth delay, GI effects, and headache
- **Significant possible interactions:** may increase levels of anticonvulsants, selective serotonin reuptake inhibitors (SSRIs), tricyclics, and warfarin
  - High-caffeine energy drinks, albuterol inhalers, and decongestants may increase side effects.
The FDA reports permanent skin discoloration with Daytrana patches.

**Pregnancy Considerations**
Medications are Category C: caution in pregnancy

**Second Line**
Nonstimulant:
- Serotonin norepinephrine reuptake inhibitor
  - Atomoxetine (Strattera):
    - ≤70 kg: 0.5 mg/kg/day initial; increase after a minimum of 3 days to target dose of 1.2 mg/kg/day; maximum of 1.4 mg/kg/day
    - >70 kg: 40 mg daily; increase after minimum of 3 days to target dose of 80 mg/day; dose may be increased to maximum of 100 mg/day after additional 2 to 4 weeks.
- α2-Agonist
  - Modest efficacy, high side effects. Consider consultation before use.
    - Clonidine XR (Kapvay): 0.1 mg once daily at bedtime; increase by 0.1 mg weekly; doses should be taken twice daily with equal or higher split dosage given at HS; maximum of 0.4 mg/day; taper when discontinued.
    - Guanfacine XR (Intuniv): 1 mg daily; increase by 1 mg weekly until 1 to 4 mg daily; taper when discontinued.

**ALERT**
Atomoxetine carries a “black box” warning regarding potential exacerbation of suicidality (similar to SSRIs). Close follow-up is recommended.

- Associated with hepatic injury in a small number of cases; check liver enzymes if symptoms develop.
- Interacts with paroxetine (Paxil), fluoxetine (Prozac), and quinidine

**ISSUES FOR REFERRAL**
Refer for children if there are additional mental health issues, developmental issues, or poor response to treatment.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Surveys have shown that parents of children with ADHD use herbals and complementary treatments frequently (20–60%) but very limited evidence to support any intervention.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Parent/teacher rating scales
- Office visits to monitor side effects and efficacy: End points are improved grades, rating scales, family interactions, and peer interactions.
- Monitor growth (especially weight) and BP.

**DIET**
There is “insufficient evidence to suggest that dietary interventions reduce the symptoms of ADHD” (2)[C].

The AAP recommends that a trial of a preservative-free, food coloring–free diet is a reasonable intervention.

PATIENT EDUCATION

- Excellent reference: http://www.parentsmedguide.org
- Teachers reference: ADDitude toolkit for parents and teachers
- CHADDS national resource center for teachers
- Key points for parents:
  - Find things the child is good at and emphasize these; reinforce good behavior; give one task at a time; stop behavior with quiet discipline; coordinate homework with teachers; and have external organization tools—charts, schedules, token systems (3).
  - Develop an individualized education plan (IEP) with the school.
- Support groups:
  - Children and Adults with Attention Deficit Disorder (CHADD): http://www.chadd.org
  - Attention Deficit Disorder Warehouse: http://www.addwarehouse.com
  - The Center for Parent Information and Resources (CPIR): https://www.parentcenterhub.org

PROGNOSIS

- May last into adulthood; plan for a transition at age 17 years.
- Relative deficits in academic and social functioning may persist into late adolescence/adulthood.
- Encourage career choices that allow autonomy and mobility.

COMPLICATIONS

- Untreated ADHD can lead to failing in school, parental abuse, social isolation, and poor self-esteem.
- Possible withdrawal when medication wears off
- Monitor growth with stimulant use. If appetite is poor, eat before the medication is given and after it wears off. Consider a shorter duration medication.
- There is an increased risk of substance abuse, which may decrease with treatment of ADHD.
- There is an increased incidence of automobile accidents and injuries, which decreases with medication.

See “Patient Education” section.

CODES

ICD10
F90.9 Attention-deficit hyperactivity disorder, unspecified type
F90.0 Attn-defct hyperactivity disorder, predom inattentive type
F90.1 Attn-defct hyperactivity disorder, predom hyperactive type

CLINICAL PEARLS

Identify treatment goals and behaviors before initiating any intervention.
Make initial treatment plan based on those goals.
Behavioral therapy for child and parents, and coordination with teachers and behavioral specialists in schools are critical for both short and long term success.
AAP recommends behavioral interventions for children age 4 to 5 years and behavioral interventions plus stimulant medications as first-line treatment for children age 6 to 17 years.
Children undergoing extreme stress (parent’s divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress.
Parents may also have ADHD and may have difficulty helping the child with organization.
BASICS

Atypical mole syndrome (AMS), also known as dysplastic nevi syndrome (DNS), B-K mole syndrome, Clark nevi syndrome, or familial atypical multiple mole melanoma (FAMMM) syndrome, is a condition characterized by a large number of pigmented nevi with architectural disorder, which arise sporadically or by inheritance and are associated with an increased risk of melanoma.

DESCRIPTION

There is no consensus on criteria for AMS.

- Elevated total body nevi count, including clinically atypical nevi, is usually >50 and often >100.
  - Larger number in hereditary AMS versus sporadic atypical nevi (as few as <10)
- Increased risk of melanoma
  - Up to 90% occurrence by age 80 years in certain high-risk individuals
  - Earlier onset than in sporadic melanoma
  - More arise de novo than from an existing nevus
  - Higher risk for appearance at unusual sites (e.g., scalp, eyes, and sun-protected areas)
- Median age of diagnosis for melanoma in AMS is 10 to 20 years earlier than the general population, with documented cases of melanoma as early as in the 2nd and 3rd decades of life.

EPIDEMIOLOGY

Incidence
Uncertain due to phenotype variability, limited data

Prevalence
Affects between 2% and 8% of fair-skinned adults as well as those with high exposure to ultraviolet radiation

ETIOLOGY AND PATHOPHYSIOLOGY

- Cyclin-dependent kinase inhibitor 2A (CDKN2A) mutations have been observed in familial DNS and multiple melanomas. The CDKN2A gene on 9p21 encodes for the proteins p16 and p14. p16 binds to CDK4/6 and is a negative cell-cycle regulator via inhibition of the CDK-cyclin D interaction needed for cell cycle progression from G1 to S. p14 functions by stabilizing the tumor-suppressor protein p53 in the G1 phase of the cell cycle.
- Familial cases of germline CDKN2A mutations are transmitted in an autosomal dominant fashion.
- No clear somatic mutation patterns in sporadic cases

Genetics
CDKN2A gene mutation is observed in 25–40% of hereditary cases, with autosomal dominant inheritance but variable expressivity and incomplete penetrance.

RISK FACTORS
Family history of melanoma or multiple nevi, sun exposure, neonatal blue-light phototherapy, history of painful sunburns

**GENERAL PREVENTION**
- Primary prevention with sun avoidance, sun protection
- Secondary prevention of melanoma with routine skin exams, biopsy of suspect lesions, and environmental risk mitigation as above

**COMMONLY ASSOCIATED CONDITIONS**
- Malignant melanoma, including ocular melanoma
- Ocular nevi
- Pancreatic cancer in CDKN2A mutation

**DIAGNOSIS**
AMS is a clinical diagnosis with various classifications schemes proposed. Although not widely accepted, diagnostic criteria, as defined by the NIH, require the three features of (i) malignant melanoma in ≥1 first- or second-degree relatives; (ii) numerous melanocytic nevi (frequently >50), some of which are clinically atypical; and (iii) nevi that have certain histologic features (1).

**HISTORY**
- Changing lesions: bleeding, scaling, size, texture, nonhealing, hyper- or hypopigmentation
- Large number of nevi
- Congenital nevi
- Sun exposure
- Prior skin biopsies
- Prior melanoma
- Immunosuppression (e.g., AIDS, chemotherapy, pancreatic cancer)
- First- or second-degree relatives with:
  - AMS
  - Melanoma
  - Pancreatic cancer

**PHYSICAL EXAM**
- Full-body skin exams
- Goal to distinguish melanoma from AMS
- ABCDE mnemonic for skins lesions concerning for melanoma: Asymmetry, Border irregularity, Color variegation, Diameter >6 mm, and Evolving lesion
  - Atypical mole (AM) is often defined as ≥5 mm and at least two other features.
  - Melanoma typically has several characteristics of ABCDEs, with increased specificity for melanoma if lesion diameter is >6 mm.

  **“Ugly duckling sign” (2)[B]:**
  - Melanoma screening strategy for increasing accuracy of diagnosis of melanoma by identifying malignant nevi straying from the predominant nevus pattern when numerous atypical nevi are present

- Most common features of AM on dermoscopy include (3)[C]:
  - Reticular pattern most common
– Uniform pigmentation most common followed by multifocal hypo/hyperpigmentation
– Homogenous brown globules
– Pigmentation with central heterogeneity and abrupt termination

Dermatoscopic features more suggestive of melanoma include (4)[C]:
– Depigmented areas
– Whitish veil
– Homogenous areas distributed irregularly, in multiple areas, or ≥25% of total lesion
– ≥4 colors

DIFFERENTIAL DIAGNOSIS
– Common nevus: acquired or congenital
– Melanoma
– Seborrheic keratosis
– Dermatofibroma
– Lentigo
– Pigmented actinic keratosis
– Pigmented basal cell carcinoma
– Blue rubber bleb nevus syndrome

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis is first suspected with history and physical exam and then confirmed by biopsy and histopathology.

Initial Tests (lab, imaging)
– Dermoscopy can be used for a more detailed exam of nevus to aid in distinguishing between benign and malignant lesions as well as for further classification to any of the 11 subtypes.
– Genetic testing is available for CDKN2A mutations, but it is not recommended outside of research studies because results cannot be adequately used for management or surveillance (5)[C].
– When the total nevus count is high and following each nevus is impractical, total body photography may aid in the evaluation of evolving nevi as well as in documenting new nevi (6)[C].

Diagnostic Procedures/Other
– Biopsy is recommended for any lesion where melanoma cannot be excluded.
– Biopsy entails full-thickness biopsy of the entire lesion with a narrow 1- to 3-mm margin of normal skin down to fat for adequate depth assessment (7)[C].
  – Excisional biopsy, elliptical or punch excision, provides the most accurate diagnosis and should be performed when possible.
  – Scoop shave biopsy can also be used, but care must be taken to not transect the lesion.
– Reexcision of mild to moderately dysplastic nevi with positive margins may not change pathologic diagnosis, but for severely dysplastic nevi, consider reexcision, with surgical margins of 2 to 5 mm (6)[C].

Test Interpretation
“Dysplastic nevus” is a term more accurately reserved as a histologic diagnosis. Features may include melanocyte proliferation in the dermoepidermal junction extending through at least three rete ridges in a specific pattern, fusing of rete ridges, dermal fibrosis, neovascularization, and
interstitial lymphocytic inflammation (6)[C].

**TREATMENT**

**MEDICATION**
No medications have been shown to treat AMS (6)[C].

**ISSUES FOR REFERRAL**
- Dermatologist for routine skin exam for those patients at high risk for melanoma
- Ophthalmologic exams for ocular nevi/melanoma screening/papilledema
- Oncology or specialized genetics study group involvement if strong family predisposition to pancreatic cancer

**ADDITIONAL THERAPIES**
- Topical chemo- and immunotherapies have been unsuccessfully attempted to treat AMs (6)[C].
- Laser treatment should be avoided because it is both unsafe and ineffective for melanocytic nevi (6)[C].

**SURGERY/OTHER PROCEDURES**
Surgical excision of all atypical nevi is not recommended because most melanomas in AMS appear de novo on healthy skin and the procedure leads to both poor cosmetic outcomes and a false sense of security. Lesions suspicious for melanoma should be biopsied or removed surgically.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Close follow-up with a dermatologist or other physician experienced with assessment of atypical nevi:
- Total body skin exam (including nails, scalp, genital area, and oral mucosa) every 6 months initially, starting at puberty; may be reduced to annually once nevi are stable
- Dermoscopic evaluation for suspected lesions
- Ocular exam for those with familial AMS
- Excision of suspected lesions
- Total body photography at baseline

**Patient Monitoring**
Monthly self-exams of skin

**PATIENT EDUCATION**
For young adults with fair skin, counsel to minimize exposure to ultraviolet radiation to reduce risk of skin cancer (USPSTF grade B).
- Fair skin: light eye, hair, or skin color, freckles
- Educate on sun avoidance, proper application of sunscreen, use of protective clothing (e.g., hats), avoidance of tanning booths and sunburns.
- Teach “ABCDE” mnemonic + “ugly duckling sign” to assess nevi and identify potential
melanomas.

- Provide instruction on skin self-exam techniques.
- A sample listing of patient-centric review sources on this topic are as follows:
  - Skin Cancer Foundation (https://www.skincancer.org/skin-cancer-information/atypical-moles)
  - Melanoma Research Foundation (https://www.melanoma.org/understand-melanoma/what-is-melanoma)

PROGNOSIS

- Most AM either regress or do not change.
- Multiple classification schemes have been developed over the years to delineate risk of melanoma in patients with AMS. Individuals with a family history of melanoma are at greatest risk. The Rigel classification system can be applied in the clinical setting. Points are assigned based on incidence of melanoma, with 1 point given for a personal history with melanoma and 2 points for each family member with melanoma (modified nuclear family consisting of first-degree relatives plus grandparents and uncles/aunts) and stratified as follows:
  - Score = 0, Rigel group 0, 6% 25-year accumulated risk for melanoma
  - Score = 1, Rigel group 1, 10% risk
  - Score = 2, Rigel group 2, 15% risk
  - Score ≥3, Rigel group 3, 50% risk
- The CDKN2A mutation has also been associated with a 60–90% risk of melanoma by age 80 years and a 17% risk for pancreatic cancer by age 75 years.

COMPLICATIONS

- Malignant melanoma
- Poor cosmetic outcomes from biopsy

REFERENCES

ADDITIONAL READING

CODES

ICD10

- D22.9 Melanocytic nevi, unspecified
- D22.4 Melanocytic nevi of scalp and neck
- D22.30 Melanocytic nevi of unspecified part of face
CLINICAL PEARLS

- In describing nevi, “atypical” is a clinical term, whereas “dysplastic” is a histologic term.
- Melanoma in AMS tends to arise from healthy skin despite a large number of atypical nevi.
- ~20% of individuals with familial AMS will develop pancreatic cancer by age 75 years.
- Patients with AMS tend to produce neoplasms in unusual sites such as the scalp, eyes, and sun-protected areas (e.g., gluteal folds).
AUTISM SPECTRUM DISORDERS
Gregory Mines, MD, MBS • Holly L. Baab, MD

BASICS

DESCRIPTION
- Group of neurodevelopmental disorders of early childhood characterized by (i) persistent deficits in social communication and interaction and (ii) restricted, repetitive patterns of behavior, interests, or activities
- Diagnostic and Statistical Manual of Mental Disorders, 5th edition: umbrella term autism spectrum disorder (ASD), which encompasses a group of pervasive developmental disorders with designations for varying severities and associated symptoms
- ASD combines former diagnoses, including autistic disorder, childhood disintegrative disorder, Asperger disorder, pervasive developmental disorder not otherwise specified (PDD-NOS), early infantile autism, childhood autism, Kanner autism, high-functioning autism, and atypical autism; many of which are still used by ICD-10 coding.
- Although symptoms must be present in the early development period, they may not be apparent until social demands exceed capacity.
- Symptoms must cause functional impairment.
- Severity levels
  - Level 1: requiring support
  - Level 2: requiring substantial support
  - Level 3: requiring very substantial support
- Specifiers for associated symptoms include: with catatonia; intellectual impairment; language impairment; known medical or genetic condition; and neurodevelopmental, mental, or behavioral disorders.
- Important to distinguish ASD from similar symptoms that could be better explained by intellectual disability or global developmental delay

EPIDEMIOLOGY
- Predominant age: onset in early childhood
- Predominant sex: male > female (4:1)

Pediatric Considerations
Symptom onset can often be seen in children <3 years of age but may not become apparent until social demands exceed capacity.

Incidence
Estimated 1 in every 110 children in the United States diagnosed per year

Prevalence
- According to the Centers for Disease Control and Prevention (CDC) in 2014, an estimated prevalence of 1 in every 59 children between the ages of 3 and 17 years carried a diagnosis of ASD.
- This has been a steady increase since 2000 when the CDC reported the prevalence to be 1 in 150.
Systematic literature reviews suggest changes in prevalence can be largely accounted for by changes in definition and increased awareness.

ETIOLOGY AND PATHOPHYSIOLOGY
- No single cause has been identified.
- General consensus: A genetic abnormality leads to altered neurologic development.
- No scientific evidence relating vaccines, such as vaccines for measles, mumps, rubella (MMR) or thimerosal causing ASDs.
- Pathophysiology is not fully understood.

Genetics
- Genetic concordance: A 2009 Swedish population-based cohort study of 2 million subjects showed a cumulative risk of 59% for monozygotic twins.
- Rate in siblings: The American College of Medical Genetics and Genomics practice guidelines lists the risk of siblings of children diagnosed with ASD without an identifiable cause to be:
  - 7% if the affected child is female
  - 4% if the affected child is male
  - >30% if there are two or more affected children

RISK FACTORS
- Male sex
- Family history
- Advanced paternal age
- Very low birth weight
- Perinatal insults including toxic exposures, teratogens, and prenatal infections.
- Maternal use of selective serotonin reuptake inhibitors (SSRIs) or valproate during pregnancy.
- Note: Epidemiologic evidence does not support an association between immunizations and ASD.

GENERAL PREVENTION
- Screening for early intervention is associated with improved prognosis, yet the median age of diagnosis in the United States is >4 years.
- Routine screening for ASD with a validated tool is recommended at 18- and 24-month well-child visits to assist with early detection.
- Screening is indicated after 24 months if parents or clinician have concerns about ASD as less severe presentations may pass earlier routine screening.
- Children with false positives for ASD frequently have some form of developmental disorder which also benefits from early intervention.
- Screening can be difficult due to variability of signs and symptoms of ASD along with the lack of unanimous consensus of social developmental milestones, thus leading to delayed diagnosis.

COMMONLY ASSOCIATED CONDITIONS
- Intellectual disability
- Attention deficit hyperactivity disorder (ADHD), anxiety, depression, or obsessive behavior
- Motor impairments including hypotonia, apraxia, toe walking, or gross motor delays
- Phenylketonuria (PKU), tuberous sclerosis, fragile X syndrome, Angelman syndrome, Rett syndrome, CHARGE syndrome, Joubert syndrome, Smith-Lemli-Opitz syndrome, Timothy
common conditions:
- Syndrome, and fetal alcohol syndrome (rare)
- Seizures (increased risk if severe mental retardation)
- Sleep issues: insomnia, circadian rhythm sleep–wake disorder, sleep-related movement disorder
- Chronic constipation, diarrhea, abdominal pain

DIAGNOSIS

HISTORY
- Listen to parents’ concerns and test early if they or you have suspicion of a neurodevelopmental disorder.
- Impairment in social-emotional reciprocity
  - Failure of normal back-and-forth conversations
  - Unable to develop peer relationships
  - Reduced sharing of interests, emotions, or affect
  - Failure to initiate or respond to social interaction
- Deficits in nonverbal communication
  - Abnormalities in eye contact or body language
  - Deficits in understanding and use of gestures
  - Lack of facial expression and nonverbal communication
- Deficits in developing, maintaining, and understanding relationships
  - Difficulties adjusting behavior to suit various social contexts
  - Difficulties in sharing imaginative play or in making friends
  - Absence of interest in peers
- Repetitive and stereotyped patterns of behavior
  - Stereotyped or repetitive motor movements, use of objects, or speech
  - Insistence on sameness, inflexible adherence to routines, or ritualized patterns of behavior with intolerance to change
  - Highly restricted, fixated interests that are abnormal in intensity or focus
  - Hyper- or hyporeactivity to sensory input or unusual interest in sensory aspects of the environment
- Prenatal, neonatal, and developmental history
- Seizure disorder
- Family history of autism, genetic disorders, learning disabilities, psychiatric illness, neurologic disorders, or mental retardation

PHYSICAL EXAM
- Measurement of growth parameters including height, weight, and head circumference because macrocephaly is present in 25% of ASD
- Vision and hearing assessment
- Speech, language, and communication assessments
- Developmental and sensorimotor testing
- Neurologic exam, including muscle tone and reflexes
- Examination for dysmorphic features consistent with genetic disorders such as fragile X syndrome and Angelman syndrome
- Wood lamp skin exam to rule out tuberous sclerosis
DIFFERENTIAL DIAGNOSIS

- Obsessive-compulsive disorder
- Elective mutism
- Language disorder/hearing impairment
- Intellectual disability/global developmental delay
- Stereotyped movement disorder
- Severe early deprivation/reactive attachment disorder
- Anxiety disorder
- Social communication disorder
- Developmental language disorder
- Acquired epileptic aphasia
- Rett syndrome
- Fetal alcohol spectrum disorder
- Tic disorder

DIAGNOSTIC TESTS & INTERPRETATION

- The Modified Checklist for Autism in Toddlers (M-CHAT) is the most commonly used test to screen for ASDs in children 16 to 30 months of age (https://m-chat.org/) (1)[B].
- The Modified Checklist for Autism in Toddlers Revised, Follow-up (M-CHAT-R/F) shows improved PPV and lower false-positive rate in children aged 16 to 30 months (https://mchatscreen.com/mchat-rf/) (1)[B].
- Screening Tool for Autism in Two-Year-Olds (STAT) shows promising evidence as level 2 screening to detect 2 year olds with autism with other developmental disorders (1)[B].
- Social Communication Questionnaire (SCQ) (formerly Autism Screening Questionnaire)—used for children age 4+ years (1)[B]

ASD screening tools for older children include: Autism Spectrum Quotient-Child (ages 4–11), Autism Spectrum Screening Questionnaire (ages 7–16), Childhood Autism Spectrum Test (ages 4–11), and the Developmental Behaviour Checklist (ages 4–18 with intellectual disabilities)

Initial Tests (lab, imaging)

- Chromosomal microarray (CMA), DNA analysis (Fragile X), and karyotype testing
- Complete blood count, serum Lead, thyroid-stimulating hormone and PKU screening
- Metabolic testing if signs of lethargy, limited endurance, unusual habits, hypotonia, recurrent vomiting and dehydration, developmental regression, or specific food intolerance
- Consider TORCH (toxoplasmosis, syphilis, varicella-zoster, parvovirus B19, rubella, cytomegalovirus, HIV, and herpes) infection workup if microcephaly present.
- Social Communication Questionnaire (SCQ)
- Consider MRI if focal neurologic symptoms

Follow-Up Tests & Special Considerations

- Children with ASD have the same general health care needs as other children and should receive the same preventative care and screening.
- Follow-up appointments and testing recommended as indicated for comorbidities
- Consider additional hearing tests such as audiometry and brainstem auditory evoked response (BAER) or consultation to audiology.
- Comprehensive speech and language evaluation
Consider genetics consult
Evaluation by multidisciplinary team; includes a psychiatrist, neurologist, psychologist, and other autism specialists
Intellectual level needs to be established and monitored
Tests used to follow autism are the following:
- Autism Behavior Checklist (ABC)
- Gilliam Autism Rating Scale (GARS)
- Childhood Autism Rating Scale (CARS)
- Autism Diagnostic Interview-Revised (ADI-R)
- Autism Diagnostic Observation Schedule-Generic (ADOS-G) Imaging

**Diagnostic Procedures/Other**
Electroencephalogram if displaying signs or symptoms suggestive of seizures

---

**TREATMENT**

**GENERAL MEASURES**
- Early intensive behavioral intervention (EIBI) involving treatment for at least 25 hours per week to address social communication, language, play skills, and maladaptive behavior leads to improvement in cognitive ability, language, and adaptive skills.
- Cognitive-behavioral therapy (CBT) has been shown to substantially reduce anxiety in older children with ASD who have average to above-average IQ.
- Targeted play therapy has led to improvements in early social communication skills.
- Programs designed for training and education of parents improve language skills and decrease disruptive behavior in children with ASD.
- Core features of a successful education program
  - High staff–student ratio 1:2
  - Individualized programming
  - Specialized teacher training with ongoing evaluation of teachers and programs
  - 25 hours a week minimum of specialized services
  - A structured routine environment
  - Ongoing program evaluation and adjustment with routine functional analysis of individual child behavioral problems
  - Family involvement

**MEDICATION**
- Autism behavior issues should be managed with maximal behavioral management.
- No true first-line medical therapy; medications used to treat targeted symptoms

**First Line**
- Currently, the only FDA-approved psychotropic medications for ASD are risperidone and aripiprazole. Risperidone (approved age >5 years; oral; initial dose: 0.01 mg/kg/dose for 2 days and then 0.02 mg/kg/dose once daily; max 0.06 mg/kg/dose) has shown short-term efficacy for treatment for irritability, repetitive behaviors, and social withdrawal.
  Aripiprazole (approved ages 6 to 17 years; oral; initial dose: 2 mg daily for 2 days, then 5 mg daily for 2 days, and then 10 mg daily; max 30 mg/day) has shown efficacy for treating short-term irritability, hyperactivity, and repetitive movements.
Stimulants (such as methylphenidate) have been efficacious in treating concomitant symptoms of ADHD such as impulsiveness, hyperactivity, and inattention; however, the magnitude of response is less than in typically developing children, and adverse effects are more frequent. SSRIs have limited evidence for autism. It has shown help in reducing ritualistic behavior and improving mood and language skills; initial choice for anxiety and depressive mood. Melatonin used for patients with concomitant sleep disorders has shown mixed efficacy.

ISSUES FOR REFERRAL
- Refer early to early learning for evaluation of behavior and language, genetic counseling, and audiology.
- Consider referrals to psychiatry, ophthalmology, otolaryngology, neurology, and nutrition.
- Refer family members to parent support groups and respite programs.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Medications such as secretin, intravenous immunoglobulin, chelation therapy, vitamin B₆, and magnesium have shown no benefit in ASD and may carry significant risks.
- Therapies such as auditory integration therapy, facilitated communication, gluten- or casein-free diets, and hyperbaric oxygen have shown no benefit.
- Therapies such as music, massage, therapeutic horseback riding, and other pet therapies merit further review.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Constant monitoring by caregivers
- Reevaluation every 6 to 12 months by physician for seizures, sleep and nutritional problems, and to follow-up prescribed medical management
- Intellectual and language testing every 2 years in childhood

DIET
- There is insufficient evidence for recommendations of any certain dietary modifications for ASD.
- Gluten- or casein-free diets have shown no benefit across several randomized clinical trials.

PATIENT EDUCATION
- Refer parents to the partners in policymaking course (https://partnersonlinecourses.com/) to learn how to advocate for their child and themselves.
- Economic costs
  - An additional $17,000 to $21,000 per year is an estimated cost for raising an ASD child.
  - Due to caretaker burden, family earnings are found to be 28% less among families with ASD compared to children without health conditions.

PROGNOSIS
- Prognosis influenced by IQ, early intervention, strength of early language skills, and psychiatric comorbidities
- The general expected course is for a lifelong need for supervised structured care; however,
some patients will develop gainful employment, independent living, and social relationships.

**COMPLICATIONS**
- Increasing incidence of seizure disorders in up to 1 in 4 children
- Increased risk for physical and sexual abuse
- With pica, increased risk of lead poisoning
- Increased risk for gastrointestinal symptoms, including weight abnormalities and abnormal stool patterns

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
Algorithm: Intellectual Disability

**CODES**

**ICD10**
- F84.5 Asperger’s syndrome
- F84 Pervasive developmental disorders
- F84.2 Rett’s syndrome

**CLINICAL PEARLS**

ALARM mnemonic from the American Academy of Pediatrics (AAP)
- ASD is prevalent (screen ALL children between 18 and 24 months).
- Listen to parents when they feel something is wrong.
- Act early: Screen all children who fall behind in language and social developmental milestones (use early learning to help with evaluation).
- Refer to multidisciplinary teams (speech and language evaluation, genetic screening, social support groups).
- Monitor support for patient and families.
BABESIOSIS
Frederick W. Nielson, MD • Daniel Nelson, DO

BASICS

DESCRIPTION
- Rare tick-borne hemolytic disease caused by intraerythrocytic protozoan parasites of the genus Babesia
- Infrequently reported outside the United States
  - Sporadic cases have been reported from
    - France, Italy, the United Kingdom, Ireland, the former Soviet Union, Mexico (1)
    - China, Italy, and Turkey have reported a reemergence of cases.
  - In the United States, infections have been reported in many states. The most endemic areas are:
    - Islands off the coast of Massachusetts (including Nantucket and Martha’s Vineyard)
    - New York (including Long Island, Shelter Island, and Fire Island); Connecticut
    - Asymptomatic infection common in these areas (1)
- Incubation period varies from 5 to 33 days:
  - Most patients do not recall specific tick exposure.
  - After transfusion of infected blood, the incubation period can be up to 9 weeks (1).
- System(s) affected: cardiovascular, gastrointestinal, hemic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic

Pediatric Considerations
Transplacental and perinatal transmission rarely reported (1,2)

Geriatric Considerations
- Morbidity and mortality higher in patients >60 years
- Cases more common in patients >70 years who have medical comorbidities

EPIDEMIOLOGY
Babesiosis affects patients of all ages. Most patients present in their 40s or 50s (1).

Incidence
- Cases reported to the Centers for Disease Control and Prevention appear to be on the rise from 911 in 2012 to 2,368 in 2017.
- Prevalence is difficult to estimate due to lack of surveillance and asymptomatic infections.
- Transfusion-associated babesiosis and transplacental/perinatal transmission have been reported (1).
- In patients at high risk for tick-borne diseases, seroconversion data show antibodies to Babesia microti in 7 of 671 individuals (1%) (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- B. microti (in the United States) and Babesia divergens and Babesia bovis (in Europe) cause most human infections (1). B. divergens and a new strain Babesia duncani appear to be more virulent. Other species identified in case reports. All share morphologic, antigenic, and genetic
Ixodid (hard-bodied) ticks, particularly *Ixodes dammini* (*Ixodes scapularis*: deer tick) and *Ixodes ricinus*, are the primary vectors. The white-footed deer mouse is the primary reservoir. Infection is passed to humans through the saliva of a nymphal-stage tick during a blood meal. Sporozoites introduced at the time of the bite enter red blood cells and form merozoites through binary fission (classic morphology on blood smear). Humans are a dead-end host for *B. microti*.

**RISK FACTORS**
- Residing in endemic areas
- Asplenia
- Immunocompromised state

**GENERAL PREVENTION**
- Avoid endemic regions during the peak transmission months of May to September (1).
- Appropriate insect repellent is advised during outdoor activities, especially in wooded or grassy areas:
  - 10–35% N,N-diethyl-meta-toluamide (DEET) provides adequate skin protection (1).
  - Acaricides, such as permethrin, provide impregnated clothing with even further protection (3).
- Early removal of ticks—daily skin checks
- Examine pets for ticks; flea/tick control for pets

**COMMONLY ASSOCIATED CONDITIONS**
- Coinfection with *Borrelia burgdorferi* and *B. microti*, particularly in endemic areas (1). Coinfection rates may be as high as ~27%.
- Coinfection with *Ehrlichia* (1)

**DIAGNOSIS**

**HISTORY**
- The tick must remain attached for at least 24 hours before the transmission of *B. microti* occurs (1).
- Travel/exposure history
- Comorbidities (immunosuppression, chronic disease)
- Fever (68–89%), fatigue (78–79%), chills (39–68%), sweats (41–56%), headache (32–75%), myalgia (32–37%), anorexia (24–25%), cough (17–23%), arthralgias (17–32%), nausea (9–22%). Other symptoms reported by case reports include abdominal pain, vomiting, diarrhea, and emotional lability.

**PHYSICAL EXAM**
- High fever (up to 40°C [104°F])
- Hemodynamic instability (shock in extremely ill)
- Hepatomegaly and splenomegaly (mild if noted)
- Rash (uncommon—if rash is present, consider concurrent Lyme disease)
- Central nervous system involvement includes headache, photophobia, neck and back stiffness,
altered sensorium, and emotional lability
• Jaundice and dark urine may develop later in course of illness.

DIFFERENTIAL DIAGNOSIS
• Bacterial sepsis
• Hepatitis
• Lyme disease; ehrlichiosis; Rocky Mountain spotted fever
• Leishmaniasis
• Malaria
• HIV; Epstein-Barr virus
• Hemolysis, elevated liver enzymes, and low platelet syndrome (in pregnancy)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
• Diagnosis requires a high index of clinical suspicion. Nonspecific laboratory clues include evidence of mild to severe hemolytic anemia, normal to slightly depressed leukocyte count (1), elevated lactate dehydrogenase or transaminase level, elevated blood urea nitrogen and creatinine, proteinuria, and hemoglobinuria (1,2).
• Definitive diagnosis is made by blood smear.
  – Wright- or Giemsa-stained peripheral blood smear demonstrates intraerythrocytic parasites (2)[B].
  – Dividing “cross-like” tetrads of merozoites (Maltese cross) are pathognomonic (2).
  – Serial blood smears may be required (low parasite load early in the illness) (2).
  – Can be confused with Plasmodium falciparum on peripheral smear
• If blood smears are negative but suspicion remains, IgM serologies through indirect immunofluorescent antibody testing (IFAT) for B. microti antigen:
  – Positive titer results vary by lab. Titers of >1:64 or a 4-fold increase from baseline are consistent with B. microti infection (4). Titers may be >1:1,024 in acute infection (2)[B].
  – Titers often elevated 8 to 12 months and can persist for years.
  – In New England, seroprevalence is 0.5–16% (4).
• Detection of B. microti by polymerase chain reaction (PCR) is more sensitive and equally specific in acute cases. PCR can also be used to monitor disease progression (2)[B]. Newer real-time PCR tests have a sensitivity and specificity approaching 100%.
• If lab tests are inconclusive and infection is strongly suspected, inoculation of laboratory animals with patient blood can reveal B. microti organisms in the blood of the animal within 2 to 4 weeks (2).

Follow-Up Tests & Special Considerations
Monitoring intraerythrocytic parasitemia helps guide treatment (3)[C].

Diagnostic Procedures/Other
Based on blood smear, history, and epidemiologic information (2)

TREATMENT
GENERAL MEASURES
In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline 100 mg BID PO to empirically treat coinfection until serologic testing is complete (1)[C].

Drug resistance has emerged in severely immunocompromised patients (2).

Consider treating asymptomatic patients if parasitemia persists for >3 months; otherwise, do not treat in absence of symptoms (1,3)[C].

### MEDICATION

#### First Line
- Mild to moderate infection with B. microti: 7 to 10 days of atovaquone 750 mg PO BID plus azithromycin 500 mg/day PO on day 1, followed by 250 mg/day (3)[B]. Pediatrics: atovaquone 20 mg/kg (max 750 mg) BID and azithromycin 10 mg/kg (max 500 mg) on day 1 and then 5 mg/kg (max 250 mg) (2)[B]. For severe B. microti infection: oral quinine 650 mg TID or QID plus IV clindamycin 300–600 mg QID for 7 to 10 days (3)[C]. Pediatrics: clindamycin 7 to 10 mg/kg (max 600 mg) TID or QID and quinine 8 mg/kg (max 650 mg) TID (2)[C].
- Persistent or relapsing babesiosis: Treat for 6 weeks, including 2 weeks after Babesia is no longer detected on blood smear (5)[B].

#### Second Line
- Combination of quinine sulfate 650 mg PO TID and clindamycin 600 mg PO TID or 1.2 g parenterally BID for 7 to 10 days is the most commonly used treatment. Pediatric: quinine 8 mg/kg (max 650 mg) every 6 to 8 hours for 7 to 10 days and clindamycin 7 to 10 mg/kg (max 600 mg) PO q6–8h for 7 to 10 days. Some experts prefer this regimen for severe infections (2) [C].
- Other drugs including tetracycline, primaquine, sulfadiazine (Microsulfon), and sulfadoxine/pyrimethamine (Fansidar) have been evaluated. Results vary. Pentamidine (Pentam) is moderately effective in diminishing symptoms and decreasing parasitemia (1)[C].

### ALERT

Clindamycin can lead to Clostridium difficile–associated diarrhea.

### ISSUES FOR REFERRAL

Severe disease: Consider consultation with hematology and infectious disease for exchange transfusion in extremely ill patients (blood parasitemia >10%, massive hemolysis, and asplenia) (2)[C].

### ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS
- If left untreated, silent babesiosis may persist for months or years (2).
- Of 139 hospitalized cases from 1982 to 1993:
  - 9 patients (7%) died.
  - 25% were admitted to the ICU.
  - 25% hospitalized for >14 days
- Alkaline phosphatase levels >125 U/L, white blood cell counts >5 × 10⁹/L, history of cardiac abnormality, history of splenectomy, presence of heart murmur, and parasitemia of 4% or
higher are associated with disease severity.

**Patient Monitoring**
The need for monitoring depends on disease severity. Severe infections: Follow hematocrit and parasitemia levels until clinical improvement, and parasitemia is <5%. Mild to moderate: Expect clinical improvement within 48 hours and complete resolution within 3 months.

**COMPLICATIONS**
- Many remain asymptomatic.
- Complications in hospitalized patients: congestive heart failure (12%), disseminated intravascular coagulation (18%), acute respiratory distress syndrome (21%), renal failure (6%), coma/lethargy (9%), death (9%)
- Other reported complications include neutropenia and myocardial infarction.
- In asplenic patients, warm autoimmune hemolytic anemia has been reported.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
B60.0 Babesiosis

**CLINICAL PEARLS**
Ticks must remain in place for 24 hours to transmit infection. Encourage daily “tick checks” if
people are exposed in high-risk areas.
Most patients do not recall tick exposure, and incubation can last up to a month.
Left untreated, silent babesial infection may persist for months or years.
First-line treatment for mild or moderate disease is atovaquone plus azithromycin.
Patients with mild-to-moderate disease should show clinical improvement within 48 hours
after starting therapy. Symptoms should fully resolve in 3 months.
Coinfection with B. burgdorferi and Ehrlichia species is common in endemic areas. In areas
endemic for Lyme disease and ehrlichiosis, consider adding doxycycline until serologic testing
is completed.


**BACK PAIN, LOW**
J. Herbert Stevenson, MD • Michael Maddaleni, MD

### BASICS

#### DESCRIPTION
- Low back pain (LBP) is extremely common and includes a wide range of symptoms involving the lumbosacral spine and pelvic girdle.
- Characterized by duration or associated symptoms
  - **Duration (1)[A]**
    - Acute (<6 weeks)
    - Subacute (>6 weeks but <3 months)
    - Chronic (>3 months)
  - **Associated symptoms (1)[A]**
    - Localized/nonspecific “mechanical” LBP
    - Back pain with lower extremity symptoms
    - Systemic and visceral symptoms
- A specific cause is not found for most patients with LBP. Most cases resolve in 4 to 6 weeks.
- Rule out “red” flag symptoms indicating the need for immediate intervention.
- **System(s) affected:** musculoskeletal, neurologic
- **Synonym(s):** lumbago, lumbar sprain/strain, low back syndrome

### EPIDEMIOLOGY

#### Incidence
- 1-year incidence for first episode: 6.3–15.3% (2)
- 1-year incidence for any episode: 1.5%–36% (2)
- A very common primary care complaint (1)

#### Prevalence
- Lifetime prevalence: 84% (1)
- Global point prevalence: 9% (1)
- Chronic point prevalence in United States: 13.1%
- Predominant sex: male = female
- **Age:** The highest incidence is in the 3rd decade (20 to 29 years); overall prevalence increases with age until age 65 years and then declines (1).

### ETIOLOGY AND PATHOPHYSIOLOGY

LBP can be commonly due to muscle spasm/tension. Estimated 39% of chronic LBP due to disk degeneration. 30% estimated to be from facet joint syndrome. Other possibilities include sacroiliac injuries/degeneration and spinal stenosis. Age-related degenerative changes of the lumbosacral spine and atrophy of supporting musculature may contribute as well (2)[A].

### RISK FACTORS
- Age (1)[A]
- Activity (lifting, sudden twisting, bending) (1)[A]
- Obesity (1)[A]
- Sedentary lifestyle (1)[A]
- Physically strenuous work (1)[A]
- Psychosocial factors—anxiety, depression, stress (1)[A]
- Genetic factors (2)
- Heavy operating equipment (2)
- Poor flexibility (2)
- Smoking (1)[A]

GENERAL PREVENTION
- Maintain normal weight (1)[A].
- Adequate physical fitness and activity (1)[A]
- Stress reduction (1)[A]
- Proper lifting technique and good posture
- Smoking cessation
- There is insufficient evidence to recommend for or against routine preventive measures in adults.

DIAGNOSIS

HISTORY
- Onset of pain (sudden or gradual) (1)
- Pain from spinal structures (musculature, ligaments, facet joints and disks) can refer to the thigh region but rarely below the knee. However, facet pain most commonly radiates to sacroiliac joint/PSIS region (1).
- Sacroiliac pain often refers to the thigh and can radiate below the knee (1).
- Irritation, impingement, or compression of lumbar nerve roots often results in more leg pain than back pain (1).
- Pain from the L1–L3 nerve roots radiates to the hip and/or thigh, whereas pain from the L4–S1 nerve roots radiates below the knee.
- Red flags
  - Recent trauma
  - Neurologic deficits
    - Bowel/bladder incontinence or urinary retention
    - Saddle anesthesia
    - Weakness, falls
  - Night pain, sweats, fever, weight loss
  - Age >70 years with or without trauma
  - Age >50 years with minor trauma
  - History of cancer
  - Osteoporosis
  - Immunosuppression, prolonged glucocorticoid use
  - IV drug use/fever (3)
- Yellow flags (predicting poor long-term prognosis):
  - Lack of social support
  - Unsupportive work environment
  - Depression and/or anxiety
– Abuse of alcohol or other substances
– History of physical or sexual abuse
– Excessive mobility in spine or other joints (2)
– Fear of reinjury, movement, or pain (2)
– Low expectation of recovery (2)
– Passive coping style (2)

Pain can be provoked with motion: flexion–extension, side-bending rotation, sitting, standing, and lifting. Pain often relieved with rest.

Radicular pain may radiate to buttocks, thighs, and lower legs.

**Pediatric Considerations**
Back pain is not normal in children and must be carefully evaluated. Trauma from high impact or hyperextension sports would be the leading cause requiring further evaluation.

**PHYSICAL EXAM**
- Observe gait, positioning, and facial expressions.
- Test lumbar spine range of motion.
- Evaluate for point tenderness or muscle spasm.
- Evaluate for signs of muscle atrophy.
- Complete thorough physical exam to assess for wide differential (full differential listed in subsequent section).
  - Completely evaluate reflexes, strength, pulses, sensation.
  - Slump test: Have patient sit on table and slump shoulders forward. Then have patient touch chin to chest and attempt to have them extend one leg at a time. Do this while continually reassessing for symptom reproduction; can be indicative of disk herniation.
  - Straight leg test: Raise the patient’s leg straight while the patient is lying down. Keep the knee straight. For more specificity, dorsiflex ankle while lifting leg. This can also evaluate for herniated disk.
  - Evaluate for saddle anesthesia, anal wink reflex.
  - FABER and FADIR test of hips bilaterally.
  - Evaluate for psychological distress that may be contributing.
  - Stork test: Stand on one leg with opposite hip held in flexion. Extend back. Pain in lumbosacral area is a positive test—consider spondylolisthesis versus facet osteoarthritis.
  - Waddell sign—overreaction to physical exam, widespread tenderness—may indicate psychological component/underlying depression.

**DIFFERENTIAL DIAGNOSIS**
- Localized/nonspecific “mechanical” LBP (87%) (1)[A]
  - Lumbar strain/sprain (70%)
  - Disk/facet degeneration (10%)
  - Osteoporotic compression fracture (4%)
  - Spondylolisthesis (2%)
  - Severe scoliosis, kyphosis
  - Asymmetric transitional vertebrae (<1%)
  - Traumatic fracture (<1%)
- Back pain with lower extremity symptoms (7%) (1)[A]
  - Disk herniation (4%)
- Spinal stenosis (3%)

**Systemic and visceral symptoms (1)[A]**

- Neoplasia (0.7%)
  - Multiple myeloma; metastatic carcinoma
  - Lymphoma/leukemia
  - Spinal cord tumors, retroperitoneal tumors
- Infection (0.01%)
  - Osteomyelitis
  - Septic discitis
  - Paraspinal abscess; epidural abscess
  - Shingles
- Inflammatory disease (0.03%)
  - Ankylosing spondylitis, psoriatic spondylitis
  - Reactive arthritis
  - Inflammatory bowel disease
- Visceral disease (0.05%)
  - Prostatitis
  - Endometriosis
  - Chronic pelvic inflammatory disease
  - Nephrolithiasis, pyelonephritis
  - Perinephric abscess
  - Aortic aneurysm
  - Pancreatitis; cholecystitis
  - Penetrating ulcer
- Other
  - Osteochondrosis
  - Paget disease
  - Cauda equina syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- No clinical benefit of routine imaging (2).
  - Imaging only recommended for progressive, severe neurologic deficits or in the setting of “red flags” (2)
  - Significant amount of false positives; evidence of possible herniated disk material seen in 20–76% of asymptomatic patients on computed tomography, magnetic resonance imaging (MRI), myelography (2)
- X-ray of the lumbar spine (1),(4)[A]
  - Not recommended for initial presentation without red flags. Defer films for 6 weeks, unless there is a history of acute trauma (fall, etc.) or high risk of disease.
  - Useful to evaluate bony etiology (e.g., fracture)
- MRI of the lumbar spine (1,4)[A] for patients presenting with neurologic deficits, failure to improve with 6 weeks of conservative treatment, or if there is a strong suspicion of cancer or cauda equina syndrome
  - Useful for suspected herniated disk, nerve root compression, or metastatic disease
- CT scan of the lumbar spine (1,4)[A]
– Appropriate alternative to MRI for patient with pacemaker, metallic hardware, or other contraindication to MRI

- Labs are unnecessary with initial presentation if no related red flags, signs, or symptoms (1,4)[A].
- If infection or bone marrow neoplasm is suspected, consider (1,4)[A]
  – Complete blood count (CBC) with differential
  – Erythrocyte sedimentation rate (ESR)
  – C-reactive protein (CRP) level

**Diagnostic Procedures/Other**
Neurosurgical consult for acute neurologic deficits or suspected cauda equina syndrome (1)[A]

---

**TREATMENT**

The primary goal is to provide supportive care and allow return to functional activity. Patients should be aware of alarm symptoms to prompt a return visit.

**MEDICATION**

**First Line**

- Physical therapy
  – McKenzie method is a prothrombin time approach for those patients who feel better with low back extension (standing up straight), among many, to help classify people with LBP and direct a specific approach that may provide the most benefit (3).
- Patient education
  – Reassure patients that pain is usually self-limited; treatment should relieve pain and improve function.
  – Limit bed rest to less than 48 hours.
  – Encouraging activity as tolerated leads to quicker recovery; walk as much as possible.
  – Early intervention with formal physical therapy (2)
  – Sit on straight backed chair (not sofa or soft cushioned chair) to maintain lumbar lordosis.
  – Strong evidence that intensive patient education is effective for long-term pain control and ability to return to work (3)
- Medications (1,4)[A]
  – Acetaminophen 325 to 650 mg PO q4–6h PRN pain (max 4 g/day)
  – Nonsteroidal anti-inflammatory drugs
    o Ibuprofen 400 to 600 mg PO 3 to 4 times daily (max 3,200 mg/day)
    o Naproxen 250 to 500 mg PO q12h (max 1,500 mg/day)
  – Manual medicine (5)[A], osteopathic manipulative treatments (OMT): myofascial, counterstrain, bilateral ligamentous techniques as well as muscle energy, if tolerated
- Obstetric considerations (6)[B]
  – Use medications cautiously in pregnancy—benefit must clearly outweigh risk.
- OMT and chiropractic care may be used in a multidisciplinary approach; may be used in the general population as well as the obstetric patient.

**Second Line**

- Second-line therapy for moderate to severe pain (1,4)[A]
- Cyclobenzaprine 5 to 10 mg PO up to TID PRN (max 30 mg/day)
- Tizanidine 2 mg PO up to TID PRN

- Avoid opioid use (If so, ≤4 days, maximum) for LBP; opioids in the setting of LBP do not have a significantly better effect than NSAIDs plus placebo or placebo alone and may cause chronic opioid dependence and/or chronic low back pain (5)[A].
- Single, small trial with topiramate has showed that it is better than placebo at improving pain/function (3)
- Topical lidocaine likely no better than placebo (3).
- Recent practice shows that physicians will prescribe Valium in people already taking naproxen—recent study shows that adding Valium to a naproxen regimen does not improve disability or pain scores.

- Other treatments (1,4)[A]
- Antidepressants (1,4)[A]
  - Tricyclic antidepressants (amitriptyline, nortriptyline, desipramine) have been shown in randomized trials to provide a small pain reduction in patients. No clear evidence that selective serotonin reuptake inhibitors are more effective than placebo in cases of chronic LBP. Treatment of concurrent depression may have positive effect on LBP.
  - Cymbalta has shown superiority to other antidepressants in decreasing pain for chronic LBP. Typically uptitrate to 60 mg daily (3).

- Injections (6)[A]
  - Facet: Therapeutic facet joint nerve blocks in the lumbar spine and lumbar intra-articular injections have all shown benefit.
  - Epidural: provide short-term relief of persistent pain associated with documented radicular symptoms caused by herniated disk (1,4,6)[A]
  - Lumbar radiofrequency: Recent randomized controlled trial showed no clinically significant improvement of LBP when radiofrequency was done with exercise program versus exercise program alone (7).

**Geriatric Considerations**
- Older persons taking nonselective NSAIDs should use a proton pump inhibitor or misoprostol for gastrointestinal protection.
- Patients taking a COX-2 selective inhibitor with aspirin should use a proton pump inhibitor or misoprostol for gastrointestinal protection.
- Age-related decline in cytochrome P450 function and polypharmacy (common in elderly patients) increases risk for adverse medication reactions.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Recent guideline updates suggest not recommending acupuncture.
- Yoga can help with chronic LBP (1,4)[A]. Recent small study also corroborated this notion. Study showed that yoga can improve long-term function and reduce pain overall.
- Spinal manipulative therapy (including osteopathic treatment) is as effective as NSAIDs and exercise for pain and functional status.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Regular exercise to manage weight and control symptoms (4)[A].
- Strongly encourage patients to remain active.
- Educate patients regarding chronicity, recurrence, and red flags (4)[A].

**Patient Monitoring**
- Reassurance is important. Follow up within 2 to 4 weeks of initial presentation to monitor progress. Most patients spontaneously improve.
  - Assess severity and quality of pain, range of motion, and other historical features (red flags).
- Reevaluate for organic causes if no adequate improvement.

**COMPLICATIONS**
- Regular NSAID use can increase risk of gastrointestinal toxicity and nephrotoxicity (1)[A].
- Acetaminophen has potential hepatotoxicity in high doses. Recommendations indicate 4 g should be the highest daily dose (1)[A].
- Centrally acting skeletal muscle relaxants and opioid agonists carry the risk for sedation, confusion, dependence, and abuse (1)[A]. Proceed with extreme caution if patients are requiring pain medications long term.

**REFERENCES**

**ADDITIONAL READING**
Algorithm: Low Back Pain, Acute

CODES

ICD10
- M54.5 Low back pain
- G89.29 Other chronic pain
- M53.3 Sacrococcygeal disorders, not elsewhere classified

CLINICAL PEARLS
- LBP is one of the most common complaints in primary care. Most cases resolve spontaneously within 4 to 12 weeks of onset.
- Assess for red flag symptoms in every patient, such as bowel/bladder incontinence, history of cancer, or recent trauma.
- Labs and imaging studies are unnecessary for most cases of back pain if no red flag symptoms are present. Symptoms typically will resolve in 6 weeks or less.
- In the absence of red flags, physical activity as tolerated speeds recovery.
- Early intervention with formal physical therapy and spinal manipulative therapy can reduce symptoms, strengthen musculature, and speed up recovery.
BACTERIURIA, ASYMPTOMATIC
Onameyore Utuama, MD, MPH ● Pius Ogenyi Ameh, BM, BCh ● Kitty Carter-Wicker, MD

BASICS

DESCRIPTION
Asymptomatic bacteriuria (ASB) is specific bacterial growth ≥10^5 CFU/mL in one and two consecutive midstream urine samples for men and women, respectively >18 years. This definition applies to individuals with no clinical symptoms (1).

EPIDEMIOLOGY

Incidence
- Premenopausal females: 1–5%
- Pregnancy: 2–10%
- Older females and males: 4–19%
- Institutionalized older population: 15–50%

Prevalence
- Variable, increased with age, female gender, sexual activity, and presence of genitourinary (GU) abnormalities
- Pregnancy: 2–10%
- Short- and long-term indwelling catheter 9–23% and 100%, respectively
- Long-term care residents in women 25–50% and men 15–40%

ETIOLOGY AND PATHOPHYSIOLOGY
- Microbiology is similar to that of other UTI, with bacteria originating from periurethral area, vagina, or gut.
- Organisms are less virulent in ASB than those causing UTI.
- The most common organism is Escherichia coli. Other common organisms are Klebsiella pneumoniae, Enterobacter, Proteus mirabilis, Staphylococcus aureus, group B Streptococcus (GBS), and Enterococcus.

Genetics
Genetic variations that reduce toll-like receptor-4 function (TLR4) have been associated with ASB by lowering innate immune response and delaying bacterial clearance.

RISK FACTORS
- Pregnancy
- Older age
- Female gender
- Sexual activity, use of diaphragm with spermicide
- GU abnormalities: neurogenic bladder, urinary retention, urinary catheter use (indwelling, intermittent, or condom catheter)
- Institutionalized elderly population
- Diabetes mellitus
• Immunocompromised status
• Spinal cord injuries or functional impairment
• Hemodialysis

COMMONLY ASSOCIATED CONDITIONS
Depends on the risk factors

DIAGNOSIS

HISTORY
• Asymptomatic
• Lack of symptoms attributable to UTI such as fever, acute dysuria (<1 week), new or worsening urinary urgency/frequency/incontinence, or acute gross hematuria

PHYSICAL EXAM
• Afebrile
• No suprapubic and costovertebral angle tenderness

DIFFERENTIAL DIAGNOSIS
• UTI
• Uncomplicated cystitis
• Contaminated urine specimen

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Urinalysis (UA):
  – The presence of pyuria, leukocyte esterase, and nitrite in ASB is common.
• Urine culture
• Screening urine culture in asymptomatic patients is indicated in only two conditions:
  – Pregnancy: screening between 12 and 16 weeks’ gestation or at first prenatal visit if later (1) [A]
  – Prior to transurethral resection of prostate (TURP) (1)[A] or any urologic interventions when mucosal bleeding is anticipated (1)[C]
• Screening for ASB in men and nonpregnant women is not recommended.

Follow-Up Tests & Special Considerations
• Noncontaminated urine specimen should be used for urine culture.
• In pregnancy, periodic screening urine culture should be done after ASB treatment (1)[A] but not required in GBS bacteriuria (2,3)[C].

Test Interpretation
• Patient with significant bacteriuria with or without pyuria and without symptoms referable to UTI should be diagnosed as ASB per Infectious Diseases Society of America.
  – Significant bacteriuria is defined based on type of urine specimen, sex, and the amount of bacteria.
  – By midstream, clean catch specimen
    o Male: >100,000 CFU/mL of single bacteria species
Female: the same criteria as male but needs two positive consecutive specimens
By catheterized specimen male and female: >100 CFU/mL of one bacterial species; required one-time collection only

- The presence of pyuria or leukocyte esterase is common but not a marker of infection.
- Positive nitrite is an indicator of the presence of bacteriuria but cannot differentiate UTI from ASB or poor collection technique.

**TREATMENT**

**GENERAL MEASURES**

**ALERT**

- Antibiotic treatment of ASB is indicated in only two conditions:
  - **Pregnancy (1)[A]**
    - Rationale: Treatment prevents up to 70% of pregnant women from developing acute pyelonephritis, which reduces the risk of low birth weight and preterm delivery that are perinatal complications (1,3,4).
  - **Prior to TURP (1)[A]**
    - Rationale: Antibiotic treatment can effectively prevent postprocedure bacteremia and sepsis.

- Treatment of ASB in other conditions (nonpregnant women, diabetic women, indwelling catheter, patients with spinal cord injury, or the elderly living in the community) does not provide any known clinical benefit, does not reduce the risk of symptomatic infection nor improve morbidity or mortality. It increases health care cost, adverse drug side effects, development of resistant organisms, and reinfection rate (1).

- Inadequate evidence to guide management in nonurologic procedure and solid organ transplant (1)

**MEDICATION**

- **Pregnancy**
  - Intrapartum antibiotic prophylaxis with IV penicillin or clindamycin (penicillin allergy) is recommended for women with GBS bacteriuria occurring at any stage of pregnancy and of any colony count to prevent GBS disease in the newborn (3)[C].
  - No consensus on choice of antibiotics and duration of treatment in pregnancy; however, the cure rate is higher for the 4 to 7 days of treatment than 1-day treatment (1)[A].
  - Choice of antibiotics should be guided by bacterial pathogen, local resistance rate, adverse effects, and comorbidities of patients (1).
  - Common oral antibiotics (FDA-B) that have been used
    - Nitrofurantoin 100 mg BID for 5 days (low level of resistance, may cause hemolysis in glucose-6-phosphate dehydrogenase deficiency)
    - Amoxicillin/clavulanate 500/125 mg BID for 5 to 7 days
    - Cefuroxime 250 mg BID for 5 days
    - Cephalexin 500 mg BID for 5 days
    - Fosfomycin 3 g for 1 single dose (not effective when glomerular filtration rate is <30 mL/min, may be used in highly resistant bacteria such as methicillin-resistant S. aureus [MRSA], vancomycin-resistant enterococci [VRE], and extended-spectrum β-lactamase
[ESBL]-producing organism bacteria) (5)
- Avoid trimethoprim in 1st trimester and near term. Avoid sulfa after 32 weeks’ gestation.
- Contraindicated: fluoroquinolones (FDA-C), tetracyclines (FDA-D)

Prior to invasive urologic interventions
- Initiate antibiotic the night before or immediately before the procedure (1)[A].
- Antibiotic should be continued until the indwelling catheter is removed postprocedure (1) [B].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
No consensus on screening frequency of ASB in pregnancy, but monthly screening of urine culture after ASB treatment is recommended except GBS (1,3).

**Patient Monitoring**
Development of any signs/symptoms of UTI should warrant antibiotic treatment.

**DIET**
Daily cranberry juice or cranberry capsules twice daily may reduce the frequency of ASB during pregnancy, but it has not been confirmed in large study (6) (see “Additional Reading”).

**PATIENT EDUCATION**
Patient should seek medical attention when UTI symptoms develop.

**COMPLICATIONS**
- Late pregnancy pyelonephritis occurs in 20–35% of women with untreated bacteriuria (20- to 30-fold higher than women with negative initial screening urine cultures or in whom bacteriuria was treated). Pyelonephritis is associated with premature delivery and worse fetal outcomes (infant with group B streptococcal infections, low-birth-weight infant). Antimicrobial treatment will decrease the risk of subsequent pyelonephritis from 20–35% to 1–4% and the risk of having a low-birth-weight baby from 15% to 5%.
- If bacteriuria remains untreated in patients who undergo traumatic urologic procedures, up to 60% develop bacteraemia after the procedure and 5–10% progress to severe sepsis/septic shock.

**REFERENCES**
6. Wing DA, Rumnney PJ, Hindra S, et al. Pilot study to evaluate compliance and tolerability of

ADDITIONAL READING

CODES

ICD10

- N39.0 Urinary tract infection, site not specified
- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- B96.1 Klebsiella pneumoniae as the cause of diseases classd elswhr

CLINICAL PEARLS

- ASB is a common and benign disorder for which treatment is not indicated in most patients.
- The presence of pyuria, leukocyte esterase, and nitrite is common in ASB and not an indication for antimicrobial treatment.
- Antibiotic treatment is indicated for ASB in pregnancy, patients who require TURP, or any urologic interventions with mucosal bleeding.
- Treatment of ASB in other conditions does not decrease the frequency of UTI or improve outcome.
- Overtreatment of ASB may result in negative consequences such as antimicrobial resistance, adverse drug reaction, and unnecessary cost.
BALANITIS, PHIMOSIS, AND PARAPHIMOSIS
John M. Doan, DO • Sarah S. Dolbear, MD

BASICS

DESCRIPTION

- Balanitis:
  - An inflammation of the glans penis
  - Posthitis is an inflammation of the foreskin.
  - Balanitis xerotica obliterans (BXO) is lichen sclerosus of the glans penis (uncommon).

- Phimosis and paraphimosis:
  - Phimosis: tightness of the distal penile foreskin that prevents it from being drawn back from over the glans
  - Paraphimosis: constriction by foreskin of an uncircumcised penis, preventing the foreskin from returning to its position over the glans; occurs after the retracted foreskin becomes swollen and engorged; a urologic emergency

- System(s) affected: renal/urologic; reproductive; skin/exocrine

ALERT

- Recurrent infection and irritations (condom catheters) can lead to phimosis.
- Recurrent balanitis, either chemical or infectious, can lead to an acquired phimosis.
- Inappropriate forced reduction of a physiologic foreskin can lead to chronic scarring and acquired phimosis; unfortunately, many times done due to instructions from health care providers
- Paraphimosis is a pediatric emergency; if left untreated, can lead to necrosis and autoamputation

EPIDEMIOLOGY

- Balanitis: predominant age: adult; predominant gender: male only
- Phimosis/paraphimosis: predominant age: infancy and adolescence; unusual in adults; risk returns in geriatrics; predominant sex: male only

Incidence
Balanitis: will affect 3–11% of males

Prevalence
Phimosis: in the United States: 8% of boys age 6 years and 1% of men >16 years of age (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Balanitis:
  - Allergic reaction (condom latex, contraceptive jelly)
  - Infections (Candida albicans, Borrelia vincentii, streptococci, Trichomonas, HPV)
  - Fixed-drug eruption (sulfa, tetracycline)
  - Plasma cell infiltration (Zoon balanitis)
  - Autodigestion by activated pancreatic transplant exocrine enzymes

- Phimosis:
– Physiologic: present at birth; resolves spontaneously during the first 2 to 3 years of life through nocturnal erections, which slowly dilate the phimotic ring
– Acquired: recurrent inflammation, trauma, or infections of the foreskin

• Paraphimosis:
  – Often iatrogenically or inadvertently induced by the foreskin not being pulled back over the glans after voiding, cleaning, cystoscopy, or catheter insertion

**Geriatric Considerations**
Condom catheters can predispose to balanitis.

**Pediatric Considerations**
Oral antibiotics predispose male infants to Candida balanitis. Inappropriate care of physiologic phimosis can lead to acquired phimosis by repeated forced reduction of the foreskin.

**RISK FACTORS**

• Balanitis:
  – Presence of foreskin
  – Morbid obesity
  – Poor hygiene
  – Diabetes; probably most common
  – Nursing home environment
  – Condom catheters
  – Chemical irritants
  – Edematous conditions: CHF, nephrosis

• Phimosis:
  – Poor hygiene
  – Diabetes by repeated balanitis
  – Frequent diaper rash in infants
  – Recurrent posthitis

• Paraphimosis:
  – Presence of foreskin
  – Inexperienced health care provider (leaving foreskin retracted after catheter placement)
  – Poor education about care of the foreskin

**GENERAL PREVENTION**

• Balanitis:
  – Proper hygiene and avoidance of allergens
  – Circumcision

• Phimosis/paraphimosis:
  – If the patient is uncircumcised, appropriate hygiene and care of the foreskin are necessary to prevent phimosis and paraphimosis.

**DIAGNOSIS**

**HISTORY**

• Balanitis:
  – Pain
- Drainage
- Dysuria
- Odor
- Ballooning of foreskin with voiding
- Redness

- Phimosis:
  - Painful erections
  - Recurrent balanitis
  - Foreskin balloons when voiding
  - Inability to retract foreskin at appropriate age

- Paraphimosis:
  - Uncircumcised
  - Pain
  - Drainage
  - Voiding difficulty

**PHYSICAL EXAM**

- Balanitis:
  - Erythema
  - Tenderness
  - Edema
  - Discharge
  - Ulceration
  - Plaque

- Phimosis:
  - Foreskin will not retract.
  - Secondary balanitis
  - Physiologic phimosis—preputial orifice appears normal and healthy.
  - Pathologic phimosis—preputial orifice has fine white fibrous ring of scar.

- Paraphimosis:
  - Edema of prepuce and glans
  - Drainage
  - Ulceration

**DIFFERENTIAL DIAGNOSIS**

- Balanitis:
  - Leukoplakia
  - Lichen planus
  - Psoriasis
  - Reiter syndrome
  - Lichen sclerosus et atrophicus
  - Erythroplasia of Queyrat
  - BXO: atrophic changes at end of foreskin; can form band that prevents retraction

- Phimosis/paraphimosis:
  - Penile lymphedema, which can be related to insect bites, trauma, or allergic reactions
  - Penile tourniquet syndrome: foreign body around penis, most commonly hair
  - Anasarca
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Microbiology culture
- Wet mount
- Serology for syphilis
- Serum glucose; ESR (if concerns about Reiter syndrome)
- STD testing
- HIV testing
- Gram stain

Diagnostic Procedures/Other
Biopsy, if persistent

Pathologic Findings
Plasma cells infiltration with Zoon balanitis

TREATMENT

GENERAL MEASURES
- Consider circumcision for recurrent balanitis and paraphimosis.
- Warm compresses or sitz baths
- Local hygiene

MEDICATION
- Balanitis:
  - Antifungal:
    - Clotrimazole (Lotrimin) 1% BID
    - Nystatin (Mycostatin) BID–QID
    - Fluconazole: 150 mg PO single dose
  - Antibacterial:
    - Bacitracin QID
    - Neomycin–polymyxin B–bacitracin (Neosporin) QID
    - If cellulitis, cephalosporin or sulfâ drug PO or parenteral:
      - Dermatitis: topical steroids QID
      - Zoon balanitis: topical steroids QID
- Phimosis:
  - 0.05% fluticasone propionate daily for 4 to 8 weeks with gradual traction placed on foreskin (2)[B]
  - 1% pimecrolimus BID for 4 to 6 weeks; not for use in children <2 years (3)[C]
- Paraphimosis:
  - Manual reduction, if possible (should be done with the patient sedated). Place the middle and index fingers of both hands on the engorged skin proximal to the glans. Place both thumbs on glans and, with gentle pressure, push on the glans and pull on the foreskin to attempt reduction. If unsuccessful, a dorsal slit will be necessary, with eventual circumcision after the edema resolves.
- Osmotic agents: granulated sugar placed on edematous tissue for several hours to reduce
edema

- Puncture technique: Multiple punctures of foreskin with a 21-gauge needle will allow edematous fluid to escape and thus allow reduction.
- Dorsal slit; done by surgeon or urologist
- BXO:
  - 0.05% betamethasone BID
  - 0.1% tacrolimus BID

ISSUES FOR REFERRAL
Recurrent infections or development of meatal stenosis

SURGERY/OTHER PROCEDURES
- Balanitis and phimosis: Consider circumcision as preventive measure.
- For paraphimosis:
  - Represents a true surgical emergency to avoid necrosis of glans
  - Dorsal slit with delayed circumcision, if reduction is not possible
  - Operative exploration if the possibility of penile tourniquet syndrome cannot be eliminated.
    Hair removal cream can be applied if a hair is thought to be the cause of the tourniquet.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - Uncontrolled diabetes
  - Sepsis
- Appropriate hygiene if condom catheters are used
- Discharge on resolution of problem

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Balanitis:
- Every 1 to 2 weeks until etiology has been established
- Persistent balanitis may require biopsy to rule out malignancy or BXO.
- Evaluation for resolution of phimosis

DIET
Weight reduction, if obese

PATIENT EDUCATION
- Need for appropriate hygiene
- Appropriate foreskin care
- Avoidance of known allergens
- No sexual activity for 2 to 3 weeks after circumcision

PROGNOSIS
Should resolve with appropriate treatment
COMPLICATIONS

- Meatal stenosis
- Premalignant changes from chronic irritation
- UTIs
- Acquired phimosis
- Unreducible paraphimosis can lead to gangrene.
- Posthitis (inflammation of the prepuce)

REFERENCES

ADDITIONAL READING

SEE ALSO

Reactive Arthritis (Reiter Syndrome)

CODES

ICD10

- N48.1 Balanitis
- N47.1 Phimosis
- N48.0 Leukoplakia of penis

CLINICAL PEARLS
- Balanitis is an inflammation of the glans penis. Posthitis is an inflammation of the foreskin. BXO is lichen sclerosus of the glans penis.
- With recurrent infections and a plaque, a biopsy should be done to rule out BXO or malignancy.
- If there is a true phimosis that interferes with appropriate hygiene, treat the phimosis with steroids or circumcision to help with hygiene.
BARRETTE ESOPHAGUS
Daniel J. Stein, MD, MPH

BASICS

DESCRIPTION
- Metaplasia of the distal esophageal mucosa from native stratified squamous epithelium to abnormal columnar (intestinalized) epithelium; likely a consequence of chronic gastroesophageal reflux disease (GERD)
- Predisposes to the development of adenocarcinoma of the esophagus

EPIDEMIOLOGY
- Predominant age >50 years, more common in men
- Estimated to be present in 1–2% of adult population
- Very rare in pediatric population

Incidence
- 10–15% of patients undergoing endoscopy for evaluation of reflux symptoms
- Incidence of esophageal adenocarcinoma (EAC) is rising in the United States (1); 6-fold increase (to 2.5 cases per 100,000) since 1970s
- Annual incidence of adenocarcinoma in all Barrett patients estimated at 0.5% per year
- Attributed to changes in smoking and obesity rather than reclassification or overdiagnosis

Prevalence
Difficult to ascertain, may be as many as 1.5 to 2 million adults in the U.S. (extrapolated from a 1.6% prevalence in Swedish general population)

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic gastric reflux injures the esophageal mucosa, triggering columnar metaplasia. Refluxed bile acids likely induce differentiation in gastroesophageal junction (GEJ) cells.
- Columnar cells in the esophagus have higher malignant potential than squamous cells. Activation of CDX2 gene and overexpression of HER2/neu (ERBB2) oncogene promotes carcinogenesis.
- Elevated levels of COX-2, a mediator of inflammation and regulator of epithelial cell growth, are associated with Barrett esophagus (BE) (1).
- Classic progression: normal epithelium → esophagitis/reflux exposure → metaplasia (BE) → dysplasia (low or high grade) → adenocarcinoma

Genetics
- Familial predisposition to GERD and BE with multiple genetic markers have been identified.
- Acquired genetic changes lead to adenocarcinoma and are being investigated as biomarkers for risk stratification and early detection.

RISK FACTORS
- Chronic reflux (>5 years)
- Hiatal hernia
- Age >50 years
Male gender
- White ethnicity—incidence in white males is much higher than white women and African American men
- Smoking history
- Intra-abdominal obesity
- Family history—at least one first-degree relative with BE or EAC

GENERAL PREVENTION
Weight loss, smoking cessation, robust intake of fruits and vegetables, and moderate wine consumption may decrease risk of BE and lower progression to esophageal cancer (1)[C].

COMMONLY ASSOCIATED CONDITIONS
GERD, obesity, hiatal hernia

DIAGNOSIS

HISTORY
- Assess underlying risk factors.
- Common GERD symptoms: heartburn, regurgitation
- Atypical symptoms include chest pain, odynophagia, chronic cough, water brash, globus sensation, laryngitis, or wheezing.
- Symptoms suggestive of complicated GERD or cancer include weight loss, anorexia, dysphagia, odynophagia, hematemesis, or melena.

ALERT
BE often not symptomatic; up to 50% of EAC and BE patients do not report GERD.

PHYSICAL EXAM
- No findings on physical exam are specific for BE.
- Findings similar to GERD

DIFFERENTIAL DIAGNOSIS
- Erosive esophagitis
- Uncomplicated GERD
- Hiatal hernia

DIAGNOSTIC TESTS & INTERPRETATION
Endoscopy with multiple biopsies demonstrating intestinal metaplasia extending ≥1 cm proximal to the GEJ is required to diagnose BE.
- Gastric cardia–type epithelium on pathology does not have clear malignant significance and may reflect sampling error.
- Specialized intestinal metaplasia at the GEJ: unclear significance, cancer risk difficult to assess with varying definitions of GEJ landmarks

ALERT
- Endoscopic screening is controversial and has not been prospectively studied. Consider screening men with chronic GERD (>5 years) and/or frequent GERD symptoms with two or more risk factors: age >50 years, white ethnicity, central obesity, smoking history, family
history of BE or EAC (ACG), or patients with multiple risk factors (1,2)[B].
- Screening for BE in the general population with GERD is not routinely recommended (1,2) [C].

**Initial Tests (lab, imaging)**
None
- Helicobacter pylori testing is not indicated. Meta-analyses show an inverse relationship between H. pylori infections and BE, which may be related to decreased acid production.
- No current biomarkers are effective for diagnosis; some under investigation for risk stratification (1)[B]

**Diagnostic Procedures/Other**
- Endoscopy: Visual identification of columnar epithelium (reddish, velvety appearance) replacing squamous epithelium (pale, glossy appearance) of the distal esophagus is standard for diagnosis/monitoring.
- Biopsies are needed to confirm the diagnosis.
- Classify disease extent: long segment (≥3 cm) versus short segment (<3 cm).
- The Prague grading system used to describe BE using the squamocolumnar junction and GEJ. “C” represents circumferential extent of the columnar changes. “M” indicates the maximal proximal extent of columnar mucosa.
- Advanced imaging techniques, such as narrow band imaging (NBI) and confocal laser endomicroscopy (not in routine use), may help identify dysplasia.
- Consider brush cytology with wide-area transepithelial sampling increases detection of dysplasia (3)[A].
- Systematic endoscopic biopsies confirm diagnosis:
  - Seattle protocol: four-quadrant biopsies at regular intervals with biopsies of visible mucosal irregularities; more time-consuming but higher diagnostic yield than random biopsies (1)[A]
  - Capsule endoscopy has lower sensitivity than conventional endoscopy.

**Test Interpretation**
- Specialized intestinal metaplasia (also called specialized columnar epithelium) is diagnostic (4) [C].
- Diagnosis of dysplasia (and grade) should be confirmed by two gastrointestinal pathologists before treatment. Benign BE is established by a single pathologist report (4)[C].
- Cardia-type columnar epithelium may predispose to malignancy (unclear risk); International Consensus Group recommends defining BE by the presence of columnar mucosa in the esophagus (noting if intestinal metaplasia is present) (4)[C].
- If screening endoscopy reveals erosive esophagitis, repeat endoscopy after 8 to 12 weeks of proton pump inhibitor (PPI) therapy to exclude underlying BE; defer biopsies until healing occurs (2)[C].

**TREATMENT**

**MEDICATION**
- The goal of medical therapy is to control GERD and reduce esophagitis.
Neither suppression of gastric acid production via high-dose PPIs nor reduction in esophageal acid exposure via antireflux surgery induces regression of BE. These therapies may, however, decrease progression/cancer risk (1)[A],(5)[B].

**First Line**
- Unlike the stepwise management of GERD without evidence of BE, all patients with BE should be treated with a daily PPI.
- Dose PPIs 30 to 60 minutes before a meal (ideally, the first meal of the day).
- Patients should remain on lifetime PPI therapy. If GERD symptoms were initially present, PPI should be increased until symptoms are controlled (2)[A].

**ALERT**
Titrate PPI therapy to symptoms; routine pH monitoring is not recommended (1)[C]. In patients with symptoms uncontrolled on PPI, manage according to current standards for treatment of uncontrolled GERD.

**ISSUES FOR REFERRAL**
- Most patients with low-grade dysplasia (except those who do not desire intervention) and all those with high-grade dysplasia or intramucosal carcinoma should be referred for endoscopic eradication of their Barrett.
- Initiate PPI therapy prior to endoscopy to reduce reactive esophagitis/atypia (2)[C].
- Refer patients considering esophagectomy (rare) to a high-volume institution.

**ADDITIONAL THERAPIES**
- Aspirin combined with high-dose twice daily PPI may reduce progression to dysplasia (not yet routinely recommended).
  - COX-2 selective inhibitor celecoxib use not shown to affect progression of Barrett dysplasia to adenocarcinoma (1)[A]
  - Consider low-dose aspirin in patients with BE and risk factors for cardiovascular disease (1)[C].
- Statins, alone or in combination with aspirin or NSAIDs, may be effective in chemoprevention but are not yet routinely recommended (1)[B].
- No dysplasia: No other therapy is generally indicated; continue regular surveillance assuming good overall patient health (3)[C],(4).
- Treatment of dysplasia:
  - Low-grade dysplasia: Refer for a discussion of endoscopic therapy (usually radiofrequency ablation or cryotherapy) to reduce the risk of progression to adenocarcinoma (3)[C],(4).
  - High-grade dysplasia: Refer for endoscopic mucosal resection and/or endoscopic therapy to prevent progression to adenocarcinoma unless unable to tolerate the procedure (3)[C],(4).
  - Intramucosal carcinoma: endoscopic resection if possible, followed by ablation of remaining Barrett, with surgery as a backup (6)[C]
  - More advanced carcinoma: Refer to oncology and surgery to discuss resection.
  - Indeterminate grade dysplasia should have a reevaluation with biopsies on increased PPI dosage.
  - Endoscopic eradication is successful in >90% of patients but often requires multiple sessions (3).
  - Patients with ablation need ongoing surveillance.
ALERT
Endoscopic eradication not recommended for most BE without dysplasia; therapy should be individualized. Continue surveillance in these patients.

SURGERY/OTHER PROCEDURES
Antireflux surgery such as fundoplication may control GERD symptoms but have not been shown to reverse BE, decrease risk of cancer, or be superior to medical therapy (1)[A].

ALERT
Antireflux surgery does not appear to decrease risk of esophageal cancer.

- Esophagectomy is definitive and can be offered as an alternative to endoscopic eradication therapy for high-grade dysplasia (1)[B] or in patients for whom endoscopic treatment has failed. Morbidity and mortality are higher than with endoscopic treatment.
  - Preferred for patients with evidence of submucosal invasion (stage T1SM2 or higher) or T1a patients with poor differentiation, lymphovascular invasion, or incomplete endoscopic mucosal resection
  - Added benefit of lymph node removal
  - Mortality rate: <5% in patients with high-grade dysplasia who are otherwise healthy
  - Serious postoperative complications: 30–50%
  - Should ideally be performed by an experienced surgeon in a high-volume center (1)[A]

COMPLEMENTARY & ALTERNATIVE MEDICINE
A prospective study of 339 men and women with BE found those taking either a multivitamin, vitamin C, or vitamin E once a day were less likely to develop EAC.

Geriatric Considerations
Surveillance or no treatment may be preferable to endoscopic eradication therapy or esophagectomy in patients who are poor operative candidates. Discontinue surveillance in patients who are not candidates for treatment.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Surveillance (to detect high-grade dysplasia or early carcinoma), although controversial, is recommended in patients with histologically confirmed BE, especially for those in high-risk groups.
- Surveillance intervals depend on grade of dysplasia (1)[C].
- Patients diagnosed with BE on initial exam do not require endoscopy in 1 year (2)[C].
- No dysplasia: Survey every 3 to 5 years.
  - Discontinue surveillance if life expectancy is ≤5 years (4)[C].
- Low-grade dysplasia: Survey every 6 to 12 months (2,3)[C],(4).
  - Routine surveillance if patients have confirmed absence of low-grade dysplasia after two consecutive endoscopies (4)[C]
- Indefinite for dysplasia: Repeat after 3 to 6 months of increased acid suppression, and if unchanged, survey every 12 months (4)[C].
- High-grade dysplasia without eradication therapy: Survey every 3 months; with eradication
therapy: Survey every 3 months for 4, then every 6 months twice, and then every 12 months (1,2)[C].

**ALERT**
Adherence to recommended surveillance protocols may improve rates of dysplasia and cancer detection.

- Continue surveillance even if the patient has had endoscopic ablation therapy, antireflux surgery, or esophagectomy.

**DIET**
Avoid foods that trigger reflux: caffeine, alcohol, chocolate, peppermint, carbonated drinks, garlic, onions, spicy foods, fatty foods, citrus, and tomato-based products.

**PATIENT EDUCATION**
- Lifestyle modifications: smoking cessation, weight loss, avoid supine position after meals, avoid tight-fitting clothes, elevate head of bed
- No evidence that treating GERD reverses BE or necessarily prevents esophageal cancer.

**PROGNOSIS**
Annual incidence of esophageal cancer in patients with BE is estimated 0.12–0.6% per year:
- Low-grade dysplasia: may be transient; cancer risk 0.7–0.8% per year (3)
- High-grade dysplasia: cancer risk 5–9% per year (2,3)
- Promising areas for research include the use of biomarkers for risk stratification, chemoprevention of neoplastic progression, capsule endoscopy for screening, and the use of vitamins and antioxidants for prevention and treatment.

**COMPLICATIONS**
Same as GERD: stricture, bleeding, ulceration

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- K22.70 Barrett’s esophagus without dysplasia
- K22.719 Barrett’s esophagus with dysplasia, unspecified
- K22.710 Barrett’s esophagus with low grade dysplasia

CLINICAL PEARLS

- The incidence of esophageal cancer is rising faster than any other major malignancy. BE is a precursor to esophageal carcinoma.
- The highest incidence of BE is in white males >50 years of age.
- Endoscopic eradication therapy is preferred for dysplasia with or without submucosal invasion.
- Esophagectomy is generally limited to patients with invasive carcinoma or those failing to respond to endoscopic therapy.
BASAL CELL CARCINOMA
William G. Farkas, DO, FS ■ Daniel J. Farkas, MD, MPH

BASICS

DESCRIPTION
Basal cell carcinoma (BCC) is the most common cancer, originating from the basal cell layer of the skin appendages.
- Rarely metastasizes but capable of local tissue destruction

Geriatric Considerations
Greater frequency in geriatric patients (Ages 55 to 75 years have 100 times the incidence when compared with those aged <20 years.)

Pediatric Considerations
- Rare in children, but childhood radiation treatment is contributory, as are frequent or severe sunburns
- The Centers for Disease Control and Prevention recommends against using tanning beds and lamps in their guidelines for cancer prevention in school-age children.

EPIDEMIOLOGY
Worldwide, the most common form of cancer

Incidence
- Incidence in the United States: 2 million cases each year; 2.5 times more common than squamous cell carcinoma (SCC); Australia has highest incidence in the world.
- White people have a 1 in 5 chance of developing BCC during their lifetime.
- Predominant age: generally >40 years, although incidence increasing in younger populations
- Predominant sex: male > female (2:1 ratio)

ETIOLOGY AND PATHOPHYSIOLOGY
- UV-induced inflammation and cyclooxygenase activation in skin
- In chromosome 9q22, mutation of PTCH1 (patched homolog 1), a tumor-suppressor gene that inhibits the hedgehog signaling pathway
- UV-induced mutations of the TP53 (tumor protein 53), a tumor-suppressor gene
- Activation of BCL2, an antiapoptosis proto-oncogene

Genetics
- Several genetic conditions increase the risk of developing BCC:
  - Albinism (recessive alleles)
  - Xeroderma pigmentosum (autosomal recessive)
  - Bazex syndrome (rare, X-linked dominant)
  - Neviod BCC syndrome/Gorlin syndrome (rare, autosomal dominant)
  - Cytochrome P450 CYP2D6 and glutathione S-transferase detoxifying enzyme gene mutations (especially in truncal BCC, marked by clusters of BCCs and a younger age of onset)
  - Mutations in the tumor suppressor gene Patched, or activated mutations in Smoothened,
resulting in upregulation of hedgehog pathway signaling

RISK FACTORS
- Chronic sun exposure (UV radiation); most common in the following phenotypes:
  - Light complexion: skin type I (burns but does not tan) and skin type II (usually burns, sometimes tans)
  - Red or blond hair
  - Blue or green eyes
- Tendency to sunburn
- Male sex, although increasing risk in women due to lifestyle changes, such as tanning beds
- History of nonmelanoma skin cancer
- Family history of skin cancer
- Chronic immunosuppression: transplant recipients (10 times higher incidence), patients with HIV, or lymphomas
- No significant association between age and recurrence rate, according to most studies

GENERAL PREVENTION
- Use broad-spectrum sunscreens of at least SPF 30 daily and reapply after swimming or sweating.
- Avoid overexposure to the sun by seeking shade between 10 am and 4 pm and wearing wide-brimmed hats and long-sleeved shirts.
- The American Cancer Society recommends cancer-related checkups every 3 years in patients 20 to 40 years old and yearly in patients >40 years.

COMMONLY ASSOCIATED CONDITIONS
- Cosmetic disfigurement because head and neck most often affected
- Loss of vision with orbital involvement
- Loss of nerve function due to perineural spread or extensive and deep invasion
- Ulcerating neoplasms are prone to infections.

DIAGNOSIS

HISTORY
Exposure to risk factors, family history

PHYSICAL EXAM
- 80% on face and neck, 20% on trunk and lower limbs (mostly women)
- Nodular: most common (50–80%); presents as pinkish, pearly papule, plaque, or nodule, often with telangiectatic vessels, ulceration, and a rolled periphery, usually on the head or neck (1)
  - Pigmented: presents as a translucent papule with “floating pigment”; more commonly seen in darker skin types; may give a blue, brown, or black appearance and be confused with melanoma (1)
- Superficial: 10–30%; light red, scaly plaque resembling eczema or psoriasis but with thin, rolled borders and central clearing, usually on trunk or extremities; least invasive of BCC subtypes (1)
- Morpheaform: 5–10%; resembles plaque with poorly defined borders; most common on head or neck (1)
DIFFERENTIAL DIAGNOSIS

- Sebaceous hyperplasia
- Epidermal inclusion cyst
- Intradermal nevi (pigmented and nonpigmented)
- Molluscum contagiosum
- SCC
- Nummular dermatitis
- Psoriasis
- Melanoma (pigmented lesions)
- Atypical fibroxanthoma
- Rare adnexal neoplasms

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Clinical diagnosis and histologic subtype are confirmed through skin biopsy and pathologic examination (2).
- Shave biopsy is typically sufficient; however, punch biopsy is more useful to assess depth of tumor and perineural invasion.
- If a genetic disorder is suspected, additional tests may be needed to confirm it.

Test Interpretation

- Nodular BCC
  - Extending from the epidermis are nodular aggregates of basaloid cells.
  - Tumor cells are uniform; rarely have mitotic figures; large, oval, hyperchromatic nuclei with little cytoplasm, surrounded by a peripheral palisade
  - Early lesions are usually connected to the epidermis, unlike late lesions.
  - Increased mucin in dermal stroma
    - Cleft formation (retraction artifact) common between BCC “nests” and stroma due to mucin shrinkage during fixation and staining
- Superficial BCC
  - Appear as buds of basaloid cells attached to undersurface of epidermis
  - Peripheral palisading
- Morpheaform BCC
  - Thin cords and strands of basaloid cells; embedded in dense, fibrous, scar-like stroma
  - Less peripheral palisading and retraction, greater subclinical involvement
- Infiltrating BCC
  - Like morpheaform BCC but no scar-like stroma and thicker, more spiky, irregular strands
  - Less peripheral palisading and retraction, greater subclinical involvement
- Micronodular BCC
  - Small, nodular aggregates of tumor cells
  - Less retraction artifact and higher subclinical involvement than nodular BCC

TREATMENT

MEDICATION

- May be especially useful in those who cannot tolerate surgical procedures and in those who
refuse to have surgery as well as for low-risk superficial and/or nodular BCC

- 5-Fluorouracil (5-FU) cream inhibits thymidylate synthetase, interrupting DNA synthesis for superficial lesions in low-risk areas; primary treatment only; 5% applied BID for 3 to 10 weeks.

- Imiquimod (Aldara) cream approved for treatment of low-risk superficial BCC; daily dosing for 6 to 12 weeks; 80% clearance rate (2)[A]

- 5-FU is reserved for superficial BCC (2); however, with nodular BCC, imiquimod has been shown to have 5-year clearance rates ranging between 75% and 85% (3)[A].

- Topical treatment failure may yield skip lesions that yield false-negative margins, making Mohs and excisional surgery potentially less effective.

Emerging therapies:

- Vismodegib, a sonic hedgehog pathway inhibitor; for patients with advanced BCC when other options are exhausted; not considered appropriate therapy for low-risk tumors (4)[B]; also beneficial for multiple BCC and BCC nevus syndrome (4)[A]. Demonstrated success with this has led to research on other hedgehog inhibitor compounds, including sonidegib, which is approved for treatment of locally advanced BCC or those who are not candidates for surgery or RT (3).

- Intralesional injection: Efficacy for small (<1 cm) nodular and superficial BCCs varies from 67% to 94% based on the type of agent used (2)[C].

- Ingenol mebutate: derived from the plant Euphorbia peplus; in one trial, 63% of lesions, significant histologic cure rates were seen 85 days after treatment, but long-term studies need to be conducted (3)[A].

- Laser therapy: Evidence for monotherapy is currently lacking in randomized controlled trials, but anecdotal evidence supports treatment for superficial BCC; in one RCT in which it was used as a pretreatment to photodynamic therapy (PDT), 1-year recurrence rates ranged from 1% to 8%, depending on the laser form used (3)[A]; one retrospective study with superpulsed carbon dioxide therapy for superficial and nodular BCC showed no recurrence in 3-year follow-up (2)[B].

ADDITIONAL THERAPIES

- Radiation therapy
  - Useful for patients, typically older, who cannot or will not undergo surgery
  - Used following surgery, particularly if margins of tumor were not cleared
  - Cure rate is ~90%.
  - Tumors that recur in areas previously treated with radiation are harder to treat, and the area is more difficult to reconstruct.
  - Local treatment
  - Recurrence rates are 7–8%.

- PDT
  - Methyl aminolevulinate and 5-aminolevulinic acid, photosensitizers, are activated by specific wavelengths of light, creating singlet oxygen radicals that destroy local tissue (no damage to surrounding or deep tissues).
  - Decades old, well studied form of treatment currently approved in Canada, Europe, Australia, and New Zealand; off-label treatment for BCC in the United States (3)
  - Useful in areas where tissue preservation is cosmetically or functionally important; considered inferior to surgical excision in terms of efficacy (5)
  - When examining 5-year recurrence rates, may be equivalent to cryotherapy
SURGERY/OTHER PROCEDURES

- More favorable for superficial versus nodular BCC (3)[A]

**SURGERY/OTHER PROCEDURES**

- Surgical excision is first-line treatment (4)[A]; specific treatment selection varies with extent and location of lesion as well as tumor border demarcation.

- High-risk areas
  - Inner canthus, nasolabial sulcus, philtrum, preauricular area, retroauricular sulcus, lip, temple, “mask areas” of the face (5)[C]

- Curettage and electrodesiccation
  - If nodular lesion <1 cm, in low-risk area, not deeply invasive
  - Avoid in the hair-bearing areas due to risk of the tumor extending down follicular structures.
  - 5-year cure rate of 91–97%; recurrence as high as 27% for high-risk lesions (2)

- Excision with postoperative margin assessment
  - Treatment of choice for low-risk lesions <2 cm in diameter
  - Goal is 4-mm margin.
  - 5-year cure rate of 98%

- Cryosurgery
  - Reserved for nodular and superficial BCC, not indicated for tumors with depth exceeding 3 mm
  - Contraindicated in hair-bearing areas and over the lower extremities (2)
  - Typically for tumors with low risk of recurrence
  - May want pre- and posttreatment biopsies (5)[C]
  - Mean recurrence rates are approximately 1%.

- Mohs surgery
  - Preferred microsurgically controlled surgical treatment for lesions in high-risk areas, recurrent lesions, and lesions exhibiting an aggressive growth pattern (5)[A]
  - 5-year recurrence rate of 2.5% (2)[A]
  - Requires referral to appropriately trained dermatologic surgeon

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Outpatient, unless extensive lesion

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Seek shade, especially between 10 am and 4 pm.
- Oral retinoids may prevent the development of new BCCs in patients with Gorlin syndrome, renal transplant recipients, and patients with severe actinic damage.

**Patient Monitoring**

- Every 6 to 12 months for first 5 years and then annually for life
- Increased risk of other skin cancers
- Recurrence:
  - Regional: surgery and/or radiation therapy
PATIENT EDUCATION

- Teach patient-appropriate sun-avoidance techniques.
- Monthly skin self-exam
- Educate patients concerning adequate vitamin D intake. Use broad-spectrum UVA/UVB sunscreen SPF 15 or higher.
- Keep newborns out of the sun. Apply sunscreen to babies 6 months or older.

PROGNOSIS

- Proper treatment yields 90–95% cure.
- Most recurrences happen within 5 years. 56% of primary high-risk BCC are reported to recur >5 years postoperatively.
- Development of new BCCs: Many patients (30–50%) will develop a new lesion within 5 years.

COMPLICATIONS

- Local recurrence and spread
- Usually, recurrences will appear within 5 years.
- Metastasis: rare (<0.1%) but metastatic disease usually fatal within 8 months.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- C44.91 Basal cell carcinoma of skin, unspecified
- C44.31 Basal cell carcinoma of skin of other and unspecified parts of face
- C44.41 Basal cell carcinoma of skin of scalp and neck

CLINICAL PEARLS
- BCC is the most common cancer, originating from the basal cell layer of the skin appendages.
- Nodular: pearly papule, plaque, or nodule often with telangiectatic vessels, ulceration, and a rolled periphery, usually on face
- Pigmented: presents as a translucent papule with “floating pigment”; more commonly seen in darker skin types
- Superficial: scaly papule or plaque with atrophic center, ringed by translucent micropapules, usually on trunk or extremities; more common in men
- Morpheaform: firm, smooth, flesh-colored, scar-like papule or plaque with ill-defined borders
- Use diagnostic keys above to differentiate between BCC and cutaneous SCC. SCC arises from actinic keratosis in 60% of cases and generally presents as an asymptomatic hyperkeratotic lesion. If unsure, biopsy or refer to a specialist.
- Some hyperpigmented BCCs may appear similar to melanoma. Remember the ABCDEs of melanoma recognition: Asymmetry, Border irregularities, Color variability, Diameter >6 mm, Enlargement. If unsure, refer to a specialist.
- The USPSTF concludes insufficient evidence and recommends for or against routine total body skin exams for melanoma, BCC, or SCC. Exams should be based on risk factors, including exposure and family and prior medical history. All patients should receive education about risks and self-exam.
BED BUGS
Fawn J. Winkelman, DO • Adam Strosberg, DNP, ARNP-BC

BASICS

DESCRIPTION
- Nocturnal obligate blood parasites residing in furniture and bedding
- 5 to 7 mm oval, reddish brown, flat, wingless morphology
- Microscopic evidence suggests a mature bed bug, Cimex lectularius, is approximately the size of an apple seed (1).

EPIDEMIOLOGY

Incidence
- Bed bug infestations are increasing in incidence and becoming more difficult to treat (2)
- Resurgence due to changes in pesticide, increased travel, use of secondhand furniture, and high turnover rates of hotel guests

Prevalence
- Infestations have increased by 10–30% across the United States (1) in public places (schools, hospitals, hotels/motels, aircraft) over the past decade (3).
- The global population of bed bugs (C. lectularius and Cimex hemipterus, family Cimicidae) has undergone a significant resurgence since the late 1990s. This is likely due to an increase in global travel, trade, and the number of insecticide-resistant bed bugs. The global bed bug population is estimated to be increasing by 100–500% annually (4).
- There are over 75 species of Insecta: Hemiptera: Cimicidae (“bed bugs”) with the 2 genera and species implicated in human infestations being C. lectularius and C. hemipterus (1).
- C. lectularius lives in urban environments and C. hemipterus lives in tropical climates.

ETIOLOGY AND PATHOPHYSIOLOGY

- Insect family Cimicidae
- Three species bite humans: C. lectularius, C. hemipterus, and Leptocimex boueti (3)[B].
- Most prevalent species is C. lectularius (3)[B]
- Found in tropical and temperate climates
- Hide in crevices of mattresses, box springs, headboards, and baseboards
- Infestations occur in hotels/motels, hospitals, cinemas, vehicles, aircraft, and homes.
- Unlike other infestations, they are not associated with hygienic deficiencies.
- Reactions range from an absent or minimal response to the typical pruritic, erythematous maculopapular rash. Less commonly, there is an urticarial or anaphylactoid response.
- Skin reactions are due to host immunologic response to parasite salivary proteins.
- Urticarial reactions are mediated via immunoglobulin (Ig) G antibody response to salivary proteins (5)[B].
- Bullous reactions caused by an IgE-mediated hypersensitivity to nitrophorin in bug saliva (5)[B]
- Bugs are attracted to body warmth and exhaled carbon dioxide (6).
- Bites do not transmit other known pathogens.
RISK FACTORS
- Immunocompromise
- High hotel turnover
- Secondhand furniture in home

GENERAL PREVENTION
- Traps typically use carbon dioxide and heat to attract and trap bugs but can be cost prohibitive (7)[B].
- Vector control: Vacuum regularly, reduce clutter, seal cracks in walls, inspect luggage and clothing.
- Launder all bedding and clothing in >130°F (50°C) for 2 hours or place in 20°F (~5°C) or cooler environment for at least 5 days.
- If present in the home, eradicate using professional extermination services. Some pest control companies use canines to detect live bed bugs and eggs based on pheromones from the bed bugs (7)[B].

DIAGNOSIS

HISTORY
- Recent travel
- Bed bug sighting; blood specks on sheets
- New skin lesions in the morning
- Intense pruritus, pain, or burning

PHYSICAL EXAM
- Characteristic lesions are erythematous pruritic papules in an irregular linear pattern (1)
- Found on body surfaces exposed during sleeping such as face, neck, arms, legs, and shoulders
- May appear hours to days after being bitten
- Patients are usually asymptomatic but may present with papular urticaria, diffuse urticaria, bullous lesions, and/or anaphylactoid symptoms.

DIFFERENTIAL DIAGNOSIS
- Urticaria; insect or spider bite; scabies
- Dermatitis herpetiformis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Skin scraping with mineral oil preparation
- Skin biopsy

Test Interpretation
- Skin scraping is negative with mineral oil, which helps to exclude scabies.
- Skin biopsy shows nonspecific perivascular eosinophilic infiltrate consistent with arthropod bite reaction.
TREATMENT

GENERAL MEASURES
- Treatment should address three areas: treatment of the skin; eradication of the infestation; and assessment for potential mental health consequences (1).
- Most patients present for the treatment of skin irritation and lesions.
- Disease is self-limited and resolves within 1 to 2 weeks.
- Treat symptomatically.

MEDICATION

First Line
- Oral antihistamines (i.e., diphenhydramine, hydroxyzine)
- Topical antipruritics (i.e., pramoxine/calamine ointment or doxepin cream)
- Topical low-potency to mid-potency corticosteroids for 2 weeks (i.e., hydrocortisone, triamcinolone)
- Systemic corticosteroids (severe cases)

ADDITIONAL THERAPIES
- If secondarily infected, use topical or oral antibiotics against Staphylococcus and Streptococcus spp. (i.e., cephalexin, tetracycline, doxycycline, clindamycin, topical mupirocin).
- Epinephrine for anaphylaxis
- Professional extermination may be necessary.
- The Centers for Disease Control and Prevention (CDC) recommends a comprehensive integrated pest management program—remove clutter, seal cracks, heat treatment, vacuum, and nonchemical pesticides.
- New approaches (more research necessary) include xenointoxication (oral arthropodicidal agent) toxic to the bed bugs.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Not necessary as disease is self-limited
- May need specific care in extreme cases or if anaphylactoid reactions
- Consider behavioral health consultation depending on the severity of the patient’s emotional reaction to the infestation.

PATIENT EDUCATION
- Avoid scratching to prevent superinfection.
- Inspect bedding, furniture, and luggage regularly.
- CDC: www.cdc.gov/parasites/bedbugs/
- EPA: http://www2.epa.gov/bedbugs
- Myth 1: Bed bugs are invisible. They are nocturnal and hide during the daytime. Adult bugs are ~1/4-inch long, and eggs are the size of a pin head.
- Myth 2: Bed bugs reproduce rapidly. Their life cycle is 4 to 5 weeks, longer than the house fly.
Myth 3: Bed bugs can live without feeding. Bugs can live 3 to 5 months without a blood meal.

Tips to prevent and control bed bugs
- Ensure infestation is bed bugs (not fleas, other insects, and/or ticks).
- Regularly wash and heat dry your clothing and bedding, especially if it touches the floor.
- EPA tips: [https://www.epa.gov/bedbugs/top-ten-tips-prevent-or-control-bed-bugs](https://www.epa.gov/bedbugs/top-ten-tips-prevent-or-control-bed-bugs)

COMPLICATIONS
- Bed bug dermatitis, allergic reactions, asthma exacerbations, anaphylaxis
- Significant psychological distress (insomnia, depression, anxiety, delusional parasitosis) (5)
- Secondary bacterial infections
- Transmission of blood-borne diseases (rare)

REFERENCES

ADDITIONAL READING
- University of Nebraska-Lincoln, Institute of Agriculture and Natural Resources: [http://lancaster.unl.edu/pest/bugs.shtml](http://lancaster.unl.edu/pest/bugs.shtml).

CODES

ICD10
- S00.96XA Insect bite (nonvenomous) of unspecified part of head, initial encounter
- S10.96XA Insect bite of unspecified part of neck, initial encounter
- S40.269A Insect bite (nonvenomous) of unspecified shoulder, initial encounter

CLINICAL PEARLS
- 90% of infestations occur within 3 feet of bedding.
- Wash bedding/clothing regularly in hot water and vacuum carpet daily or steam clean daily.
- Inspect furniture, bedding, and luggage regularly.
Bed bugs have become resistant to over-the-counter (OTC) products (permethrin, cyfluthrin, bifenthrin, and deltamethrin or fluvalinate and esfenvalerate).
**BEHAVIORAL PROBLEMS, PEDIATRIC**
Ginny L. Gottschalk, MD ● William G. Elder, PhD

**BASICS**

**DESCRIPTION**
Behavior that disrupts at least one area of psychosocial functioning. Commonly reported behavioral problems are as follows:

- Noncompliance: active or passive refusal to do as requested by parent or other authority figure
- Temper tantrums: loss of internal control that leads to crying, whining, breath holding, or aggressive behavior
- Sleep problems: difficulty going to sleep or staying asleep at night, nightmares, and night terrors
- Nocturnal enuresis: bed wetting that occurs in children ≥5 years of age with no medical problems
  - Primary: children who have never been dry at night
  - Secondary: children dry at night for at least 6 months
- Functional encopresis: repeated involuntary fecal soiling that is not caused by organic defect or illness
- Problem eating: “picky eating,” difficult mealtime behaviors
- Normative sexual behaviors: developmentally appropriate behaviors in children in the absence of abuse
- Thumb-sucking: can be problematic if persists past eruption of primary teeth as teeth alignment may be impacted

**EPIDEMIOLOGY**

- Noncompliance issues: manifest as children develop autonomy; slightly more common in males; decreases with age
- Temper tantrums: 87% of 18- to 24-month-old children; 91% of 30- to 36-month-old children; 59% of 3.5- to 4-year-old children; in children with severe tantrums, 52% have other behavioral/emotional problems (1).
- Sleep problems
  - Night waking in 25–50% of infants 6 to 12 months
  - Bedtime refusal in 10–30% of toddlers
  - Nightmares in 10–50% of preschoolers; peaks between ages 6 and 10 years
  - Night terrors in 1–6.5% early childhood; peaks between ages 4 and 12 years
  - Sleepwalking frequently in 3–5%; peaks between ages 4 and 8 years (2)
- Nocturnal enuresis
  - At least 20% of children in the 1st grade wet the bed occasionally; 4% wet ≥2 times per week.
  - At 10 years of age, 7% in boys, 3% in girls (3)
- Functional encopresis
  - Rare before age 3 years, most common in 5- to 10-year-olds; more common in boys (4)
- Problem eating
  - Prevalence peaks at 50% at 24 months of age; no relation to sex/ethnicity/income (5)
- Normative sexual behaviors
  - Common in 3- to 5-year-olds; less observed in >5-year-olds because more covert
  - Thumb-sucking: decreases with age; most children spontaneously stop between 2 and 4 years.

**COMMONLY ASSOCIATED CONDITIONS**
- Noncompliance: If excessive or aggressive, rule out depression, compulsive patterns, adjustment disorder, inappropriate discipline
- Temper tantrums: difficult child temperament, stress, normal development
- Sleep problems: inconsistent bedtime routine or sleep schedule, stimulating bedtime environment; can be associated with hyperactive behavior, poor impulse control, and poor attention in young children (2). Acute or chronic anxiety is associated with insomnia. Long-acting stimulant medications disturb sleep quality.
- Enuresis: secondary often with medical problems, especially constipation, and frequent behavior problems, especially attention deficit hyperactivity disorder (ADHD) and autism
- Functional encopresis: enuresis, urinary tract infection (UTIs), ADHD
- Normative sexual behaviors: normal development; family stressors such as separation or divorce

**DIAGNOSIS**

**HISTORY**
- Noncompliance: history from caregivers and teachers, if possible; direct observation of child or child–caregiver interaction
  - Criteria: problematic for at least some adults, leading to difficult interactions for at least 6 months
  - Reduces child’s ability to take part in structured activities
  - Creates stressful relationships with compliant children
  - Disrupts academic progress; places child at risk for physical injury
- Temper tantrums: focus on development, family functioning, or violence; may consist of stiffening limbs and arching back, dropping to floor, shouting, screaming, crying, pushing/pulling, stamping, hitting, kicking, throwing, or running away (1)
- Sleep disorders: ask about sleep and bedtime routine during well-child visit, such as the Bedtime problems, Excessive daytime sleepiness, Awakenings during the night, Regularity and duration of sleep, and Snoring (BEARS) screen (2)
- Nocturnal enuresis: onset and duration; dry overnight previously; daytime wetting or any associated genitourinary symptoms; family history of enuresis; medical and psychosocial history; constipation; child and caregiver’s motivation for treatment; voiding diary
- Problem eating: review of child’s diet, growth curves, nutritional needs, and caregiver’s response to behavior (5)
- Normative sexual behaviors: onset, frequency, and setting; recent changes or stressors in family; occurs alone or with other children; disruptive, intrusive, or coercive in nature

**PHYSICAL EXAM**
- Nocturnal enuresis
  - Abdominal Exam: enlarged bladder, kidneys, or fecal masses
  - Neurologic exam: reflexes and strength of lower extremities; back for dimpling or hair tufts
– Genitourinary exam
  o Males: meatal stenosis, hypospadias, epispadias, phimosis
  o Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; wide vaginal orifice with scar or healed laceration may be evidence of abuse.
  o Rectal exam if constipated
• Functional encopresis
  – Abdominal exam for masses or tenderness; rectal exam for tone, size of rectal vault, fecal impaction, masses, fissures, hemorrhoids; back for dimpling or hair tufts (4)

DIFFERENTIAL DIAGNOSIS
• Temper tantrums: disruptive mood dysregulation disorder (DMDD)—distinguishable because of baseline irritable mood between outbursts and older age (6 to 18 years)
• Normal development

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
• For nocturnal enuresis: urinalysis (dipstick test OK); if abnormal, consider urine culture.
  – For secondary enuresis: serum glucose, creatinine, thyroid-stimulating hormone (TSH)
  – Urinary tract imaging and urodynamic studies if significant daytime symptoms with history or diagnosis of UTI or history of structural renal abnormalities
• For functional encopresis: TSH for hypothyroidism or celiac disease if poor growth or family history; urinalysis and culture if enuresis or features of UTI (4)
  – Spine imaging if evidence of spinal dysraphism or if both encopresis and daytime enuresis; barium enema if suspect Hirschsprung disease

Follow-Up Tests & Special Considerations
Sleep disorders: Sleep studies may be performed in children if there is a history of snoring and/or observed apnea spells to rule out obstructive sleep apnea (OSA); daytime ADHD-type symptoms may be present (2).

Diagnostic Procedures/Other
• Pediatric symptom checklist:
• National Initiative for Children’s Healthcare Quality (NICHQ) Vanderbilt Assessment (ADHD screen):
  http://www.myadhd.com/vanderbiltparent6175.html
• Child Sexual Behavior Inventory: completed by female caregiver to assist with differentiation of normative versus abnormal behaviors particularly those related to sexual abuse:
  https://www.nctsn.org/measures/child-sexual-behavior-inventory

TREATMENT
GENERAL MEASURES
• Educate caregiver about specific behavioral problem.
• Parent management training programs and techniques are effective for many child behavior problems.
• Noncompliance: For extreme disobedience, consider parent training programs. May need formal screening for ADHD, obsessive-compulsive disorder (OCD), oppositional defiant
disorder (ODD), or conduct disorder (CD).

- **Temper tantrums**: Remind caregiver this is a normal development.
  - Tantrums are not attention seeking, though they may indicate child needs more attention. Attention should be given when child is not tantruming.
  - If tantrum is set off by external factors, such as hunger or overtiredness, then correct.
  - Other methods for dealing with a tantrum include one of the following:
    - Ignore the tantrum; place child in time-out (1 minute for each year of age); hold/restrain child until calm; provide child with clear, firm, and consistent instructions as well as enough time to obey.

- **Sleep problems**: Educate caregiver at well-child checks about importance of bed routine and consistency, and consistency in response to sleep disruptions. Specific recommendations may also include (2):
  - Graduated extinction: ignore cries for specified period; check at or increasing intervals
  - Fading: gradual decrease in direct contact with the child as they fall asleep; goal is for the child to fall asleep independently.
  - If fearful, special routines or aromatherapy sprays may help the child feel more secure.

- **Nocturnal enuresis**
  - Bed-wetting alarm: first-line therapy; caregivers set an alarm to take child to the bathroom; 2/3 of children respond; if enuresis returns, will often resolve with a second trial.
  - Decrease fluids an hour before bedtime.
  - Other behavioral interventions: small reward for each dry night; responsibility training (if developmentally appropriate, child changes sheets); healthy bowel and bladder habits during the day (3)

- **Functional encopresis**
  - First disimpaction: oral polyethylene glycol solution; l; if unsuccessful, mineral oil enemas
  - Maintenance therapy
    - Medical: polyethylene glycol, fiber, lactulose
    - Behavior modification: toileting after meals for 10 minutes 2 to 3 times a day, star charts, and rewards (4)[C]

- **Problem eating**
  - Avoid punishment, prodding, or rewards. Offer a variety of healthy foods at every meal; limit milk to 24 oz per day and decrease juice (5)[C].

- **Normative sexual behavior**: No treatment needed; caregivers should not punish or admonish; gently redirect behavior when in public setting.
  - Curiosity about sex characteristics is common in children as young as 2–5 years old, including interest in looking at others, intruding on physical boundaries, and touching their mother’s breasts. Sexual play such as “doctor” is common; 60–80% of children engage in sexual play before age 13 (6).

- **Thumb-sucking**: praise children when not sucking their thumb, offer alternatives that are soothing (e.g., stuffed toys), negative reinforcement such as a bandage around or bitters on the thumb (5)

**MEDICATION**

Most pediatric behavioral issues respond well to nonpharmacologic therapy:

- **Sleep disorders**
  - Cognitive-behavioral therapy and sleep hygiene are first-line treatment; no recommended pharmacotherapy
– After behavioral methods are exhausted, melatonin 0.5 to 10.0 mg PO can be tried in concert with behavior modification. However, this is not approved by the Food and Drug Administration for children.

Nocturnal enuresis
– First line: Desmopressin; decreases urine output and episodes; does not lead to full resolution. Ages 6+: 0.2 mg 1 hour before bedtime; titrate to 0.6 mg. Consider use for special occasions (sleepovers). Intranasal formulations can cause severe hyponatremia, resulting in seizures and death in children (3).
– Second line: Anticholinergic agent (e.g., oxybutynin) works as control, not cure; oxybutynin 5 mg before bedtime
– Third line: Tricyclic antidepressants (e.g., imipramine) have similar outcomes to desmopressin (e.g., one fewer wet night in 7-night period) (3).
– Behavioral interventions are first-line treatment. Medications are inferior to alarms.

ISSUES FOR REFERRAL
– A patient who exhibits self-injurious behaviors, slow recovery time from tantrums, more tantrums in the home than outside the home, or more aggressive behaviors toward others may require referral to a psychologist or psychiatrist.
– Children with chronic insomnia or anxiety that interferes with sleep should be referred to a psychologist or psychiatrist.
– With enuresis and OSA symptoms, refer for sleep studies because surgical correction of airway obstruction often improves or cures enuresis and daytime wetting.
– Must distinguish sexual behavior problems: Developmentally inappropriate behaviors—greater frequency or earlier age than expected—becomes a preoccupation, recurs after adult intervention/corrective efforts. If abuse is not suspected, consider referral to a child psychologist. If abuse is suspected, must report to child protective services.
– If disimpaction by either manual or medical methods is unsuccessful, consult gastroenterology or general surgery. Patients who show no improvement after 6 months of maintenance medical therapy should be referred to gastroenterology (4).
– Thumb-sucking resistant to behavioral intervention and threatening oral development may be evaluated by a pediatric dentist for use of habit-breaking dental appliances (5).

ONGOING CARE

DIET
Nutrition is very important in behavioral issues. Avoiding high-sugar foods and caffeine and providing balanced meals have been shown to decrease aggressive and noncompliant behaviors in children.

PATIENT EDUCATION

REFERENCES

CODES

ICD10
- F91.9 Conduct disorder, unspecified
- F91.1 Conduct disorder, childhood-onset type
- F91.2 Conduct disorder, adolescent-onset type

CLINICAL PEARLS

- Well-child visits provide opportunities for screening for these common conditions.
- Noncompliance: In extreme disobedience, child may need to be screened for ADHD, OCD, ODD, or CD.
- Self-injurious behaviors, slow recovery time, more tantrums in the home than outside the home, or more aggressive behaviors toward others may require referral to a psychologist or psychiatrist.
- Parental education, including a review of age-appropriate discipline, is a key component of treatment.
BELL PALSY
Assim AlAbdulKader, MD, MPH ● Jason Chao, MD, MS

BASICS

DESCRIPTION
An acute, usually unilateral, peripheral facial nerve palsy of unknown etiology. Herpes-mediated viral inflammatory/immune mechanism is the likely cause of most cases, causing subsequent swelling and compression of cranial nerve VII (facial) and the associated vasa nervorum.

EPIDEMIOLOGY
- Affects 0.002% of the population annually
- No race, geographic, or gender predominance
- Median age of onset is 40 years but affects all ages
- Accounts for about half of all cases of unilateral facial paralysis
- Occurs with equal frequency on the left and right sides of the face
- Most patients recover, but as many as 30% are left with facial disfigurement and pain

Incidence
- 25 to 30 cases per 100,000 people in the United States per year
- Lowest in children ≤10 years of age; highest in adults ≥70 years of age
- Higher among pregnant women (3 times the risk)

Prevalence
Affects 40,000 Americans every year

ETIOLOGY AND PATHOPHYSIOLOGY
- Results from damage to the facial cranial nerve (VII)
- Exact pathogenesis is still controversial; infective, immune, and ischemic mechanisms are potential contributors
- The most likely cause is activation of latent herpes virus (herpes simplex virus [HSV] type 1 and herpes zoster virus) in cranial nerve ganglia
- Inflammation of cranial nerve VII causes edema of perineurium and subsequent compression and possibly degeneration of both the nerve and the associated vasa nervorum
- Ischemia from microangiopathy associated with diabetes mellitus

Genetics
Reported case series suggest potential genetic predisposition, but it remains unclear which factors are inherited

RISK FACTORS
- Pregnancy, especially in the 3rd trimester or in the 1st postpartum week
- Immunocompromised status
- Diabetes mellitus, possibly secondary to microvascular ischemia
- Age ≥30 years
- Exposure to cold temperatures
- Upper respiratory infection (e.g., coryza, influenza)
Chronic hypertension (HTN)
Obesity
Migraine headache

COMMONLY ASSOCIATED CONDITIONS
- Herpes simplex virus (HSV)
- Herpes zoster virus (HZV)
- Lyme disease
- Diabetes mellitus
- Hypertension (HTN)
- Ramsay Hunt syndrome
- Sjögren syndrome
- Sarcoidosis
- Eclampsia
- Amyloidosis

DIAGNOSIS

HISTORY
- Time course of the illness: rapid onset (over 24–48 hours) of sudden and progressive unilateral lower motor neuron-type facial weakness
- Peak of symptoms occur within 48–72 hours
- Predisposing factors: history of Bell palsy, recent viral infection, tick bite, trauma, new medications, HTN, diabetes mellitus
- Associated symptoms (in 50–60% of cases):
  - Mastoid or postauricular pain
  - Hyperacusis: increased sensitivity to sounds (nerve to the stapedius muscle)
  - Dysgeusia: alteration of taste on the ipsilateral anterior 2/3 of the tongue (chorda tympani branch of the facial nerve)
  - Numbness on the ipsilateral side of the face
  - Skin rash (suggestive of herpes zoster, Lyme disease, or sarcoidosis)
  - Decreased lacrimation or salivation (parasympathetic effects)

PHYSICAL EXAM
- Neurologic
  - Flaccid paralysis of muscles on the affected side, including the forehead.
    - Impaired ability to raise the ipsilateral eyebrow
    - Impaired closure of the ipsilateral eye
    - Impaired ability to smile, grin, or purse the lips
    - Bell phenomenon: upward diversion of the eye with attempted closure of the lid
  - Determine if the weakness is caused by either a central (upper motor neuron) or peripheral (lower motor neuron) lesion
    - In contrast to low motor neuron lesions, the forehead muscles are usually spared in upper motor neuron lesions
  - Patients may complain of numbness, but no deficit is present on sensory testing
  - Examine for involvement of other cranial nerves, especially trigeminal, glossopharyngeal,
and hypoglossal

- Head, ears, eyes, nose, and throat (HEENT)
  - Carefully examine to exclude a space-occupying lesion
  - Perform pneumatic otoscopic exam
- Skin: Examine for erythema migrans (Lyme disease) and vesicular rash (herpes zoster virus)

**DIFFERENTIAL DIAGNOSIS**

- Misdiagnosis is not uncommon (10.8%)
- Facial cranial nerve palsy etiologies include:
  - Congenital causes: genetic syndromes, birth-related trauma, developmental hypoplasia of facial muscles
  - Acquired causes: infective (herpes zoster virus, otitis media, Lyme, tuberculosis [TB], HIV), inflammatory (vasculitis, sarcoidosis, autoimmune), neoplastic (benign, malignant), cerebrovascular (stroke, aneurysm), and traumatic

<table>
<thead>
<tr>
<th>Clinical approach based on facial palsy pattern (1) [B]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Recurrent, ipsilateral palsy: neoplasm of the nerve (schwannoma) or adjacent structures (parotid, temporal bone, or cerebellopontine angle [CPA])</td>
</tr>
<tr>
<td>- Bilateral palsy: neurologic (Guillain-Barré syndrome) or associated with neoplasm (lymphoma, disseminated carcinomatosis, malignant pachymeningitis); rare: cryptococcal meningitis associated with HIV, autoimmune (MS, myasthenia gravis, Sjögren), sarcoidosis, granulomatosis with polyangiitis</td>
</tr>
<tr>
<td>- Palsy at birth: segmental developmental palsy (associated with synkinesis, recovers spontaneously)</td>
</tr>
<tr>
<td>- Facial palsy syndromes: Ramsay Hunt (rash in the ear [zoster oticus] and/or mouth caused by varicella-zoster virus [VZV]), Melkersson-Rosenthal (orofacial edema, recurrent facial palsy, and fissured tongue), Heerfordt-Waldenström (parotid enlargement, anterior uveitis, facial palsy, and fever)</td>
</tr>
</tbody>
</table>

**DIAGNOSTIC TESTS & INTERPRETATION**

Bell palsy is a clinical diagnosis. It is not recommended to obtain routine lab testing or diagnostic imaging in new-onset Bell palsy (2) [C]. However, further testing may be considered in:

- Atypical presentation of facial palsy
- Recurrent facial palsy
- Slowly progressive disease >3 weeks
- Lack of improvement after 4 months

**Initial Tests (lab, imaging)**

- Blood glucose level (if diabetes a consideration)
- Complete blood count, C-reactive protein/erythrocyte sedimentation rate to rule out inflammatory process
- Lyme serology: enzyme-linked immunosorbent assay or IFA, followed by Western blot for IgM, IgG for Borrelia burgdorferi
- Consider rapid plasma reagin (RPR) test
- Consider HIV test
- Consider titers for VZV, rubella, cytomegalovirus, hepatitis A, hepatitis B, and hepatitis C
- Salivary polymerase chain reaction (PCR) for HSV-1 or herpes zoster virus (mostly for
Follow-Up Tests & Special Considerations
- Trauma: facial radiographs to evaluate for fractures
- Contrast-enhanced CT: to evaluate for stroke or temporal bone fracture
- Gadolinium-enhanced MRI: to evaluate for brain or parotid neoplasms
- Invasive diagnostic procedures are not indicated because biopsy could further damage the nerve

Diagnostic Procedures/Other
- Electromyography (EMG)
- Nerve Conduction Study (NCS)
- Parotid gland biopsy: considered if no recovery with negative imaging at 7 months

Test Interpretation
Test results mainly help determine prognosis and surgical planning, if indicated.

TREATMENT

GENERAL MEASURES
- Artificial tears should be used to lubricate the cornea
- The ipsilateral eye should be patched and taped shut at night to avoid drying and infection

MEDICATION
- Corticosteroids decrease inflammation and limit nerve damage, thereby increase the number of patients who make full recovery and reduce disabling sequelae (NNT = 10) (3)[A].
- Antiviral alone has no benefit over placebo (4), hence the use of antivirals as a monotherapy in new-onset Bell palsy is not recommended (2).
- The combination of corticosteroids and antivirals is more effective than corticosteroids alone for complete recovery, and for resolution of excessive tear production and motor dyskinesis (4)[B].
- Corticosteroids:
  - Recommended in all Bell palsy cases (2),(5)[A]
  - Should be started within 72 hours of symptoms onset (2)[A]
  - Prednisolone 50 mg PO daily (in 1 or 2 divided doses) for 10 days, or prednisone 60 mg PO daily for the first 5 days, and then tapering dose (by 10 mg/day) the next 5 days. Both regimens are equally effective (3)[A]
  - Precautions: Use with discretion in patients with peptic ulcer disease and diabetes
  - Contraindications: documented hypersensitivity, preexisting infections (TB, systemic mycosis)
- Antivirals:
  - Should not be used alone (4)[A], rather in combination with steroids (4)[B]
  - Valacyclovir has a higher bioavailability than acyclovir.
  - Valacyclovir 1,000 mg PO TID for 7 days (2,5)
  - Precautions: Use with discretion in patients with chronic kidney disease
  - Contraindications: documented hypersensitivity
Pregnancy Considerations
Steroids should be used cautiously during pregnancy; consult with an obstetrician. Acyclovir and valacyclovir are considered category B drugs in pregnancy by the U.S. Food and Drug Administration.

ISSUES FOR REFERRAL
Patients should be referred to a facial nerve specialist when they experience worsening neurologic findings at any point, ocular symptoms developing at any point, or incomplete recovery at 3 months after onset of initial symptoms (2)[C].

ADDITIONAL THERAPIES
- Physical therapy: insufficient evidence that physical therapy combined with drug treatment has positive effect on grade and time of recovery compared with drug treatment only (2),(6)[C]
- Electrostimulation and mirror biofeedback rehabilitation have limited evidence of effect.
- Acupuncture with strong stimulation has shown some therapeutic promise but no clear recommendations (2)[B].
- Routine use of eye-protective measures for patients with incomplete eye closure is recommended (5)[A].

SURGERY/OTHER PROCEDURES
- Surgical treatment of Bell palsy remains controversial and is reserved for intractable cases.
- There is insufficient evidence to decide whether surgical intervention is beneficial or harmful in the management of Bell palsy (2)[B].
- In those cases where surgical intervention is performed, cranial nerve XII is surgically decompressed at the entrance to the meatal foramen where the labyrinthine segment and geniculate ganglion reside.
- Decompression surgery should not be performed >14 days after the onset of paralysis because severe degeneration of the facial nerve is likely irreversible after 2 to 3 weeks.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Patients should start steroid treatment immediately and be followed for 12 months.
- Patients who do not recover complete facial nerve function should be referred to ENT and/or ophthalmology specialist(s) for further management.

PATIENT EDUCATION
FamilyDoctor.org from American Academy of Family Physicians:
https://familydoctor.org/condition/bells-palsy

PROGNOSIS
- Most patients achieve complete spontaneous recovery within 2 weeks; >80% recover within 3 months.
- 85% of untreated patients will experience the first signs of recovery within 3 weeks of onset.
- 16% are left with a partial palsy, motor synkinesis, and autonomic synkinesis.
- 5% experience severe sequelae, and a small number of patients experience permanent facial
weakness and dysfunction.

- The Sunnybrook and House-Brackmann (H-B) facial grading systems are clinical prognostic models that identify Bell palsy patients at risk for nonrecovery at 12 months (7)[B].
- Poor prognostic factors include the following:
  - Age >60 years
  - History of recurrence
  - Complete facial weakness
  - HTN
  - Ramsay Hunt syndrome
  - House-Brackmann (H-B) grade ≤II
- Treatment with corticosteroids and the Sunnybrook score are significant factors for predicting nonrecovery at 1 month.
- Patients with no improvement or progression of symptoms should be referred to ENT (5)[A] and may require neuroimaging to rule out neoplasms (5)[A].

**COMPLICATIONS**

- Corneal abrasion or ulceration
- Steroid-induced hyperglycemia, psychological disturbances; avascular necrosis of the hips, knees, and/or shoulders
- Steroid use can unmask subclinical infection (e.g., TB)

**CODES**
ICD10
G51.0 Bell’s palsy

**CLINICAL PEARLS**

- Look closely at the voluntary movement on the upper part of the face on the affected side; in Bell palsy, all of the muscles are involved (weak or paralyzed), whereas in a stroke, the upper muscles are spared (because of bilateral innervation).
- Do not obtain routine labs or diagnostic imaging in a typical new-onset Bell palsy patient.
- Initiate steroids immediately following the onset of symptoms.
- Protect the affected eye with lubrication and taping.
- In areas with endemic Lyme disease, Bell palsy should be considered due to Lyme disease until proven otherwise.
BIPOLAR I DISORDER
Wendy K. Marsh, MD, MS

BASICS

DESCRIPTION
- Bipolar I (BP-I) is an episodic mood disorder of at least one manic or mixed (mania and depression) episode that causes marked impairment, psychosis, and/or hospitalization; major depressive episodes are not required but usually occur.
- Symptoms are not caused by a substance or general medical condition.

Geriatric Considerations
In new onset in older patients (>50 years of age) a workup for organic or chemically induced pathology is strongly recommended. Medications for adults are generally found efficacious in older adults, although high quality studies are lacking. Pay strict attention to pharmacokinetic issues, drug–drug interactions, side effects, and need for ongoing monitoring (e.g., lithium level and renal monitoring q3–6mo with lithium use).

Pediatric Considerations
Diagnosis is based on the same set of symptoms applied to adults. Need for clarity of symptoms is critical to differentiate between attention deficit hyperactivity disorder (ADHD), oppositional defiant disorder (ODD), disruptive mood dysregulation, and other diagnoses with overlapping symptoms that are common in childhood.

Pregnancy Considerations
- Pregnancy does not reduce risk of mood episodes.
- Need to weigh risk of exposure to mood episode to that of medication
- Avoid divalproex due to high teratogenicity risk.
- Postpartum carries high risk of severe acute episode with psychosis and/or infanticidal ideation.

EPIDEMIOLOGY
Onset usually between 15 and 30 years of age, average of 25 years

Prevalence
- 1.0–1.6% lifetime prevalence
- Equal among men and women (manic episodes more common in men; depressive episodes more common in women)
- Equal among races; however, clinicians tend to diagnose schizoaffective in African Americans with BP-I.

ETIOLOGY AND PATHOPHYSIOLOGY
Genetic predisposition and major life stressors can trigger initial and subsequent episodes:
- Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)
- Magnetic resonance imaging (MRI) findings suggest abnormalities in prefrontal cortical areas, striatum, and amygdala that predate illness onset (1)[C].
**Genetics**
- Monozygotic twin concordance 40–70%
- Dizygotic twin concordance 5–25%
- 50% have at least one parent with a mood disorder.
- First-degree relatives are 7 times more likely to develop BP-I than the general population.

**RISK FACTORS**
Genetics, major life stressors, or substance abuse

**GENERAL PREVENTION**
No known way to prevent onset, but treatment adherence and education help to prevent relapses.

**COMMONLY ASSOCIATED CONDITIONS**
Substance abuse (60%), ADHD, anxiety disorders (~50%), and eating disorders

**DIAGNOSIS**
- The diagnosis of BP-I requires at least one manic or mixed episode (simultaneous mania and depression). Although a depressive episode is not necessary for the diagnosis, 80–90% of people with BP-I also experience depression.
- Manic episode, Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) criteria (2)
  - Distinct period of abnormally and persistently elevated, expansive, or irritable mood plus increased activity or energy for at least 1 week (or any duration if hospitalization is necessary)
  - During the period of mood disturbance, three or more of the “DIG FAST” symptoms must persist (four if the mood is only irritable) and must be present to a significant degree.
    - Distractibility
    - Insomnia, decreased need for sleep
    - Grandiosity or inflated self-esteem
    - Flight of ideas or racing thoughts
    - Agitation or increase in goal-directed activity
    - Speech pressured/more talkative than usual
    - Taking risks: excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g., financial or sexual)
  - Mixed specifier: when three or more symptoms of opposite mood pole are present during primary mood episode, for example, mania with mixed features (of depression)

**HISTORY**
- Collateral information makes diagnostics more complete and is often necessary for a clear history.
- History: safety concerns (e.g., Suicidal/homicidal ideation? Safety plan? Psychosis present?), physical well-being (e.g., Number of hours of sleep? Weight change? Substance abuse?), personal history (e.g., Talkative? Risky driving? Excessive spending? Credit card debt? Promiscuity? Other risk-taking behavior? Legal trouble?), substance use (e.g., did the mood change precede or occur subsequent to substance use)
PHYSICAL EXAM

- Mental status exam in acute mania
  - General appearance: bright clothing, excessive makeup, disorganized or discombobulated, psychomotor agitation
  - Speech: pressured, difficult to interrupt
  - Mood/affect: euphoria, irritability, expansive, labile
  - Thought process: flight of ideas (streams of thought occur to patient at rapid rate), easily distracted
  - Thought content: grandiosity, paranoia, hyperreligiosity
  - Perceptual abnormalities: 3/4 of manic patients experience delusions, grandiose, or paranoia.
  - Suicidal/homicidal ideation: aggression toward self or others; suicidal ideation is common with mixed episode.
  - Insight/judgment: poor/impaired

See “Bipolar II Disorder” for an example of a mental status exam in depression.

With mixed episodes, patients may exhibit a combination of manic and depressive mental states.

DIFFERENTIAL DIAGNOSIS

- Other psychiatric considerations: unipolar depression ± psychotic features, schizophrenia, schizoaffective disorder, personality disorders (particularly antisocial, borderline, histrionic, and narcissistic), ADD ± hyperactivity, substance-induced mood disorder
- Medical considerations: epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid) disease, multiple sclerosis
- In children, consider ADHD and ODD.

DIAGNOSTIC TESTS & INTERPRETATION

- BP-I is a clinical diagnosis.
- The Mood Disorder Questionnaire is a self-assessment screen for history of mood elevation (thus presumed bipolar diagnosis) (sensitivity 73%, specificity 90%).
- Patient Health Questionnaire-9 helps to determine the presence and severity of a depressive episode.

Initial Tests (lab, imaging)

- TSH, CBC, BMP, LFTs, RPR, HIV, ESR
- Drug/alcohol screen with each presentation
- Dementia workup if new onset in elderly
- Consider brain imaging (CT, MRI) with initial onset of mania to rule out organic cause (e.g., tumor, infection, or stroke), especially with onset in elderly and if psychosis is present.

Diagnostic Procedures/Other

Consider EEG if presentation suggests temporal lobe epilepsy (hyperreligiosity, hypergraphia).

TREATMENT

GENERAL MEASURES

- Ensure safety.
Psychotherapy for depression (e.g., cognitive-behavioral therapy, social rhythm, interpersonal) in conjunction with medications

Regular daily schedule, exercise, a healthy diet, and sobriety

MEDICATION

- Acute mania (3,4)[B]
  - First line
    - Lithium monotherapy (see lithium)
    - Atypical Antipsychotic: quetiapine, risperidone/paliperidone, aripiprazole, asenapine, or cariprazine monotherapy
    - Divalproex
    - Lithium or divalproex plus atypical antipsychotic (quetiapine, aripiprazole, risperidone, asenapine)
  - Second line
    - Olanzapine
    - Carbamazepine
    - Lithium plus divalproex
    - Lithium or divalproex plus olanzapine
    - Ziprasidone
    - Haloperidol
    - Electroconvulsive Therapy (ECT)

- Acute bipolar I depression (4)
  - First line
    - Quetiapine monotherapy
    - Lurasidone adjunctive to lithium or divalproex
    - Lithium
    - Lamotrigine
    - Lurasidone monotherapy
  - Second line
    - Divalproex
    - Cariprazine
    - SSRI/bupropion adjunctive
    - Olanzapine* + fluoxetine
    - ECT

*Side effects concerns: Weight gain, metabolic syndrome, and extrapyramidal symptoms (EPS) warrant vigilance and monitoring by the clinician.

Treatment mood stabilizer(s) or other psychotropic medications. When combining, use different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium)

- Lithium (Lithobid, Eskalith, generic): dosing: 600 to 1,200 mg/day divided BID–QID; start 600 to 900 mg/day divided BID–TID, titrate based on blood levels. Warning: caution in kidney and heart disease; use can lead to diabetes insipidus or thyroid disease. Caution with diuretics or ACE inhibitors; dehydration can lead to toxicity (seizures, encephalopathy, arrhythmias). Pregnancy Category D (Ebstein anomaly). Monitor: Check ECG >40 years, TSH, BUN, creatinine, electrolytes at baseline and every 6 months; check level 5 to 7 days after initiation or dose change, then every 2 weeks × 3, and then every 3 months (goal: 0.8 to 1.2 mmol/L).
**Anticonvulsants**
- Divalproex sodium, valproic acid (Depakote, Depakene, generic): dosing: Start 250 to 500 mg BID–TID; maximum 60 mg/kg/day. Black box warnings: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D. Monitor CBC and LFTs at baseline and every 6 months; check level 5 days after initiation and dose changes (goal: 50 to 125 μg/mL).
- Carbamazepine (Equetro, Tegretol, generic): dosing: 800 to 1,200 mg/day PO divided BID–QID; start 100 to 200 mg PO BID and titrate to lowest effective dose. Warning: Do not use with tricyclic antidepressant (TCA) or within 14 days of an monoamine oxidase inhibitor (MAOI). Caution in kidney/heart disease; risk of aplastic anemia/agranulocytosis, enzyme inducer; pregnancy Category D. Monitor CBC and LFTs at baseline and every 3 to 6 months; check level 4 to 5 days after initiation and dose changes (goal: 4 to 12 μg/mL).
- Lamotrigine (Lamictal, generic): dosing: 200 to 400 mg/day; start 25 mg/day for 2 weeks, then 50 mg/day for 2 weeks, then 100 mg/day for 1 week, and then 150 mg/day. (Note: Use different dosing if adjunct to valproate.) Warning: Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney/liver/heart disease; pregnancy Category C
- Oxcarbazepine (Trileptal) dosing: 300 mg PO QD. Titrate to 1,800 to 2,400/day max.

**Atypical antipsychotics**
- Side effects: orthostatic hypotension, metabolic side effects (glucose and lipid dysregulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome (NMS), prolactinemia (except aripiprazole [Abilify]), increased risk of death in elderly with dementia-related psychosis, pregnancy Category C
- Monitor LFTs, lipids, glucose at baseline, 3 months and annually; check for EPS with Abnormal Involuntary Movement Scale (AIMS) and assess weight (with abdominal circumference) at baseline; at 4, 8, and 12 weeks; and then every 3 to 6 months; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.
- Aripiprazole (Abilify): dosing: 15 to 30 mg/day; less likely to cause metabolic side effects
- Asenapine: dosing: 5 to 10 mg sublingual BID
- Cariprazine: dosing: 1.5 to 3mg/day only for depression; 3 to 6 mg/day mood elevation
- Lurasidone: dosing: 20 to 60 mg/day; FDA-approved for bipolar depression
- Olanzapine (Zyprexa, Zydis, generic): dosing: 5 to 20 mg/day; most likely to cause metabolic side effects (weight gain, diabetes)
- Paliperidone dosing: 6 mg q am; may cause agranulocytosis, cardiac arrhythmias
- Quetiapine (Seroquel, Seroquel XR, generic): dosing: in mania, 200 to 400 mg BID; in bipolar depression, 50 to 300 mg QHS; XR dosing 50 to 400 mg QHS
- Risperidone (Risperdal, Risperdal Consta, generic): dosing: 1 to 6 mg/day divided QD–QID; IM preparation available (q2wk)
- Ziprasidone (Geodon): dosing: 40 to 80 mg BID; less likely to cause metabolic side effects. Caution: QTc prolongation (>500 ms) has been associated. Consider ECG at baseline.

**Avoid**
- TCAs and serotonin norepinephrine reuptake inhibitor (SNRI); may increase mood cycling risk

**ISSUES FOR REFERRAL**
- Refer to psychiatry, depends on knowledge level of the doctor, stability of patient
- Patients benefit from a multidisciplinary team, including a primary care physician, psychiatrist, and therapist.
ADDITIONAL THERAPIES

- Electroconvulsive therapy can be helpful in acute or treatment-resistant mania and depression.
- Modest evidence supports transcranial magnetic stimulation, ketamine infusion, armodafanil for sleep deprivation, and levothyroxine in bipolar depression.
- Blue-blocking glasses or dark therapy for mania/full spectrum 10,000 lux mid-morning light for depression

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admit if dangerous to self or others.
- To admit involuntarily, the patient must have a psychiatric diagnosis (e.g., BP-I) and present a danger to self or others, or the mental disease must be inhibiting the person from obtaining basic needs (e.g., food, clothing, shelter).
- Nursing: Alert staff to potentially dangerous or agitated patients. Acute suicidal threats need continuous observation.
- Discharge criteria determined by safety

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Regularly scheduled visits support adherence with treatment.
- Frequent communication among primary care doctor, psychiatrist, and therapist

Patient Monitoring
Mood charts are helpful to monitor symptoms.

PATIENT EDUCATION

- National Alliance on Mental Illness (NAMI): http://www.nami.org/
- Depression and Bipolar Support Alliance (DBSA): http://www.dbsalliance.org

PROGNOSIS

- Frequency and severity of episodes are related to medication adherence, consistency with therapy, quality of sleep, and support systems.
- 40–50% of patients experience another manic episode within 2 years of first episode.
- 25–50% attempt suicide, and 15% die by suicide.
- Substance abuse, unemployment, psychosis, depression, and male gender are associated with a worse prognosis.

CODES

ICD10

- F31.9 Bipolar disorder, unspecified
- F31.10 Bipolar disorder, current episode manic without psychotic features, unspecified
- F31.30 Bipolar disorder, current episode depressive, mild or moderate severity, unspecified

CLINICAL PEARLS

- BP-I is characterized by at least one manic or mixed episode that causes marked impairment; major depressive episodes usually occur but are not necessary.
- 25–50% of BP-I patients attempt suicide, and 15% die by suicide.
- There is no known way to prevent BP-I, but treatment adherence and education helps reduce further episodes.
- Goal of treatment is to decrease the intensity, length, and frequency of episodes as well as greater duration of euthymia (healthy mood) between episodes.
Bipolar II Disorder
Wendy K. Marsh, MD, MS

**BASICS**

**DESCRIPTION**
Bipolar II (BP-II) is a mood disorder characterized by at least one episode of major depression (with or without psychosis) and at least one episode of hypomania, a nonsevere mood elevation.

**Geriatric Considerations**
In new onset in older patients (>50 years of age) a workup for organic or chemically induced pathology is strongly recommended. Medications for adults are generally found efficacious in older adults, although high quality studies are lacking. Pay strict attention to pharmacokinetic issues, drug-drug interactions, side effects, and need for ongoing monitoring (e.g., lithium level and renal monitoring q3–6mo with lithium use).

**Pediatric Considerations**
Diagnosis is based on the same set of symptoms applied to adults. Need for clarity of symptoms is critical to differentiate between attention deficit hyperactivity disorder (ADHD), oppositional defiant disorder (ODD), disruptive mood dysregulation, and other diagnoses with overlapping symptoms that are common in childhood.

**Pregnancy Considerations**
- Pregnancy does not reduce risk of mood episodes.
- Need to weigh risk of exposure to mood episode to that of medication
- Avoid divalproex due to high teratogenicity risk.
- Postpartum carries high risk of severe acute episode with psychosis and/or infanticidal ideation.

**EPIDEMIOLOGY**
Onset usually between 15 and 30 years of age

**Prevalence**
- 0.5–1.0% lifetime prevalence
- More common in women

**ETIOLOGY AND PATHOPHYSIOLOGY**
Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)

**Genetics**
Heritability estimate: >77%

**RISK FACTORS**
Genetics, major life stressors, or substance abuse

**GENERAL PREVENTION**
No known way to prevent onset, but treatment adherence and education can help to prevent further episodes.
COMMONLY ASSOCIATED CONDITIONS
Substance misuse, ADHD, anxiety disorders, and eating disorders

DIAGNOSIS

- Diagnostic and Statistical Manual of Mental Disorders, 5th edition criteria: one hypomanic episode and at least one major depressive episode. The symptoms cause unequivocal change in functioning noticed by others but not severe enough to cause marked impairment (1)[C].
- Hypomania is a distinct period of persistently elevated, expansive, or irritable mood, different from usual euthymic mood, including increase in activity or energy lasting at least 4 days:
  - The episode must include at least three of the “DIG FAST” symptoms below plus increased energy (four if the mood is only irritable):
    o Distractibility
    o Insomnia, decreased need for sleep
    o Grandiosity or inflated self-esteem
    o Flight of ideas or racing thoughts
    o Agitation or increase in goal-directed activity (socially, at work or school, or sexually)
    o Speech pressured/more talkative than usual
    o Taking risks: excessive involvement in pleasurable activities that have high potential for painful consequences (e.g., sexual or financial)
- Major depression
  - Depressed mood or diminished interest and four or more of the “SIG E CAPS” symptoms are present during the same 2-week period:
    o Sleep disturbance (e.g., trouble falling asleep, early-morning awakening)
    o Interest: loss or anhedonia
    o Guilt (or feelings of worthlessness)
    o Energy, loss of
    o Concentration, loss of
    o Appetite changes, increase or decrease
    o Psychomotor changes (retardation or agitation)
    o Suicidal/homicidal thoughts
  - Rapid cycling is ≥4 mood episodes in 12 months (major depression or hypomania).
  - Mixed specifier: when three or more symptoms of opposite mood pole are present during primary mood episode, for example, hypomania with mixed features (of depression)

Note: If symptoms have ever met criteria for a full manic episode or hospitalization was necessary secondary to manic/mixed symptoms or psychosis was present, then the diagnosis is BP-I.

HISTORY

- Collateral information makes diagnostics more complete and is often necessary for a clear history.
- History: safety concerns (e.g., Suicidal/homicidal ideation? Safety plan? Psychosis present?), physical well-being (e.g., Number of hours of sleep? Substance abuse?), personal history (e.g., Risky driving? Excessive spending? Credit card debt? Promiscuity? Other risk-taking behavior? Legal trouble?), substance use (e.g., Did the mood change precede or occur subsequent to substance use?)
PHYSICAL EXAM

- Mental status exam in hypomania
  - General appearance: usually appropriately dressed, with psychomotor agitation
  - Speech: may be pressured, talkative, difficult to interrupt
  - Mood/affect: euphoria, irritability/congruent, or expansive
  - Thought process: may be easily distracted, difficulty concentrating on one task
  - Thought content: usually positive, with “big” plans
  - Perceptual abnormalities: none
  - Suicidal/homicidal ideation: low incidence of homicidal or suicidal ideation
  - Insight/judgment: usually stable/may be impaired by their distractibility

- Mental status exam in depression
  - General appearance: unkempt, psychomotor retardation, poor eye contact
  - Speech: low, soft, monotone
  - Mood/affect: sad, depressed/congruent, flat
  - Thought process: ruminating thoughts, generalized slowing
  - Thought content: preoccupied with negative or nihilistic ideas
  - Perceptual abnormalities: 15% of depressed patients experience hallucinations or delusions.
  - Suicidal/homicidal ideation: Suicidal ideation is very common.
  - Insight/judgment: often impaired

DIFFERENTIAL DIAGNOSIS

- Other psychiatric considerations
  - BP-I disorder, unipolar depression, personality disorders (particularly borderline, antisocial, and narcissistic), ADHD, substance-induced mood disorder

- Medical considerations
  - Epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid disease), multiple sclerosis

DIAGNOSTIC TESTS & INTERPRETATION

- BP-II is a clinical diagnosis.
- Mood Disorder Questionnaire, self-assessment screen for history of mood elevation (thus presumed bipolar diagnosis)
  - Hypomania Checklist-32 distinguishes between BP-II and unipolar depression (sensitivity 80%, specificity 51%) (2)[B].
  - Patient Health Questionnaire-9 helps to determine the presence and severity of depression.

Initial Tests (lab, imaging)

- Rule out organic causes of mood disorder during initial episode.
- Drug/alcohol screen is prudent with each presentation.
- Dementia workup if new onset in elderly
- With initial presentation: Consider complete blood count (CBC), chem 7, thyroid-stimulating hormone (TSH), liver function tests (LFTs), antinuclear antibody, rapid plasma reagin, HIV, and erythrocyte sedimentation rate.
- Consider brain imaging (computed tomography, magnetic resonance imaging) with initial onset of hypomania to rule out organic cause, especially with onset in the elderly.
TREATMENT

GENERAL MEASURES
- Ensure safety.
- Psychotherapy for depression (e.g., cognitive-behavioral therapy, social rhythm, interpersonal, family focused) in conjunction with medications
- Regular daily schedule, exercise, a healthy diet, and sobriety have been shown to help.
- Stress reduction
- Patient and family education
- Refer to psychiatrist

MEDICATION
- Acute mood elevation (3,4)[C]
  - First line
    - Quetiapine
    - Lithium monotherapy
    - Atypical, other: risperidone, aripiprazole, ziprasidone, asenapine, monotherapy
    - Divalproex
  - Second line
    - Haloperidol
    - Paliperidone
    - Lithium plus divalproex
    - Lithium or divalproex plus atypical
- Acute bipolar II depression (4)
  - First line
    - Quetiapine monotherapy
  - Second line
    - Lithium
    - Lamotrigine
    - Bupropion adjunct
    - Electroconvulsive therapy
- When combining, use different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium) (2)[A].
- Lithium (Lithobid, Eskalith, generic): dosing: 600 to 1,200 mg/day divided BID–QID; start 600 to 900 mg/day divided BID–TID, titrate based on blood levels. Warning: caution in kidney and heart disease; use can lead to diabetes insipidus or thyroid disease. Caution with diuretics or angiotensin-converting enzyme inhibitors; dehydration can lead to toxicity (seizures, encephalopathy, arrhythmias). Pregnancy Category D (Ebstein anomaly). Monitor: Check ECG >40 years, TSH, blood urea nitrogen, creatine, electrolytes at baseline and every 6 months. Check level 5 to 7 days after initiation or dose change, then every 2 weeks × 3, and then every 3 months (goal: 0.8 to 1.2 mmol/L).
- Anticonvulsants
  - Divalproex sodium, valproic acid (Depakote, Depakene, generic): dosing: Start 250 to 500 mg BID–TID; maximum 60 mg/kg/day. Black box warnings: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D. Monitor CBC and LFTs at baseline and every 6 months; check level 5 days after initiation and dose changes (goal: 50 to 125 μg/mL).
– Lamotrigine (Lamictal, generic): dosing: 200 to 400 mg/day; start 25 mg/day for 2 weeks, then 50 mg/day for 2 weeks, then 100 mg/day for 1 week, and then 150 mg/day. (Note: Use different dosing if adjunct to valproate.) Warning: Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney/liver/heart disease; pregnancy Category C

Atypical antipsychotics
– Side effects: orthostatic hypotension, metabolic side effects (glucose and lipid dysregulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome (NMS), prolactinemia (except aripiprazole), increased risk of death in elderly with dementia-related psychosis, pregnancy Category C
– Monitor LFTs, lipids, glucose at baseline, 3 months and annually; check for EPS with Abnormal Involuntary Movement Scale (AIMS), and assess weight (with abdominal circumference) at baseline; at 4, 8, and 12 weeks; and then every 3 to 6 months; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.
– Aripiprazole (Abilify): dosing: 15 to 30 mg/day; less likely to cause metabolic side effects
– Asenapine: dosing: 5 to 10 mg sublingual BID
– Lurasidone: dosing: 20 to 60 mg/day; less likely to cause metabolic side effects
– Paliperidone: dosing 6 mg every morning; may cause agranulocytosis, cardiac arrhythmias
– Quetiapine (Seroquel, Seroquel XR, generic): dosing: in mania, 200 to 400 mg BID; in bipolar depression, 50 to 300 mg QHS; XR dosing 50 to 400 mg QHS
– Risperidone (Risperdal, Risperdal Consta, generic): dosing: 1 to 6 mg/day divided QD–QID; IM preparation available (q2wk)
– Ziprasidone (Geodon): dosing: 40 to 80 mg BID; less likely to cause metabolic side effects. Caution: QTc prolongation (>500 ms) has been associated with use (0.06%). Consider ECG at baseline.

Unipolar antidepressants
– Bupropion (Wellbutrin): dosing: 150 to 300 mg PO total dose per day.

Avoid
– Tricyclic antidepressants; increases mood cycling risk

Issues for referral
– Refer to psychiatry; depends on knowledge level of the doctor, stability of patient
– Patients benefit from a multidisciplinary team, including a primary care physician, psychiatrist, and therapist.

Additional therapies
– Electroconvulsive therapy can be helpful in acute or treatment-resistant depression.
– Modest evidence supports transcranial magnetic stimulation, vagus nerve stimulation, ketamine infusion, sleep deprivation, and hormone therapy (e.g., thyroid) in bipolar depression.
– Blue-blocking glasses or dark therapy for mood elevation

Admission, inpatient, and nursing considerations
– Admit if dangerous to self or others.
– To admit involuntarily, the patient must have a psychiatric diagnosis (e.g., BP-I) and present a danger to self or others, or the mental disease must be inhibiting the person from obtaining basic needs (e.g., food, clothing).
– Nursing: Alert staff to potentially dangerous or agitated patients. Acute suicidal threats need
continuous observation.
- Discharge criteria determined by safety

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Regularly scheduled visits support adherence with treatment.
- Frequent communication among primary care doctor, psychiatrist, and therapist

**Patient Monitoring**
Mood charts are helpful to monitor symptoms.

**PATIENT EDUCATION**
- Depression and Bipolar Support Alliance (DBSA): [http://www.dbsalliance.org](http://www.dbsalliance.org)

**PROGNOSIS**
- Bipolar is a lifelong diagnosis.
- Frequency and severity of episodes are related to medication adherence, consistency with therapy, quality of sleep, and support systems.
- 25–50% attempt suicide and 15% die by suicide.
- Substance abuse, unemployment, psychosis, depression, and male gender are associated with a worse prognosis.

Algorithm: Depressive Episode, Major

CODES
ICD10
F31.81 Bipolar II disorder

CLINICAL PEARLS

- BP-II is characterized by at least one episode of major depression and one episode of hypomania.
- Patients may not recognize symptoms and or decline treatment during a hypomanic episode; they may enjoy the elevated mood and productivity.
- Patients with BP-II are at great risk of both attempting and completing suicide.
BASICS

DESCRIPTION
- Animal bite rates vary by species: dogs (60–90%), cats (5–20%), rodents (2–3%), humans (2–3%), and (rarely) other animals, including snakes
- System(s) affected: potentially any

Pediatric Considerations
Young children are more likely to sustain bites and have bites that include the face, upper extremity, or trunk.

EPIEMIOLOGY
- All ages, but children > adults
- Dog bites, male > female; cat bites, female > male

Incidence
- 3 to 6 million animal bites per year in the United States (1)
- Account for 1% of all injury-related ED visits
- 1–2% will require hospital admission, and 20 to 35 victims die from dog bite complications, annually.

ETIOLOGY AND PATHOPHYSIOLOGY
- There are over 60 million pet dogs and 45 million pet cats in the United States.
- Dog bites are far more common than cat bites. Most dog bites are from a domestic pet known to the victim.
- Most (~90%) cat bites are provoked.
- Human bite wounds are typically incurred by striking another in the mouth with a clenched fist.
- Human bites also occur incidentally (e.g., paronychia due to nail biting, thumb sucking, or nonmalicious bites to the face, breasts, or genital areas).
- Animal bites can cause tears, punctures, scratches, avulsions, or crush injuries.
- Contamination by oral flora leads to infection.
- Dog bites are typically crush-type wounds. Cat bites are more often puncture-type wounds.

RISK FACTORS
- Older, male dogs are more likely to bite.
- Clenched-fist human bites are frequently associated with the use of alcohol or drugs.
- Patients presenting >8 hours following the bite are at greater risk of infection.

GENERAL PREVENTION
- Instruct children and adults about animal hazards.
- Enforce animal control laws.
- Educate pet owners.
DIAGNOSIS

HISTORY
- Detailed history of the incident (provoked or unprovoked); type/breed of animal; vaccine status; whereabouts of animal
- Site of the bite
- Geographic setting
- Underlying medical history—particularly comorbid diseases and immunocompromise.
- Ascertain immunization history (tetanus in particular)

PHYSICAL EXAM
- Dog bites
  - Hands and face most common site of injury in adults and children, respectively
  - More likely to have associated crush injury
- Cat bites
  - Predominantly involve the hands, followed by lower extremities, face, and trunk
- Human bites
  - Intentional bite: semicircular or oval area of erythema and bruising, with/without break in skin
  - Clenched-fist injury: small wounds over the metacarpophalangeal joints from striking the fist against another’s teeth
- Signs of wound infection include fever, erythema, swelling, tenderness, purulent drainage, and lymphangitis.
- Document neurovascular status
- Signs of tenosynovitis (hand/finger bites): finger held in flexion; fusiform swelling; pain along tendon sheath; pain with active/passive extension of the affected digit.

ALERT
Cat bites are twice as likely to become infected as are dog bites and have higher risks of osteomyelitis, tenosynovitis, and septic arthritis.

Pediatric Considerations
Human bite marks on a child with an intercanine distance >3 cm are likely from an adult and should raise concerns about child abuse.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Gram stain and culture wound drainage
  - If wound fails to heal, culture for atypical pathogens (fungi, Nocardia, and mycobacteria); keep bacterial cultures for 7 to 10 days (some pathogens are slow-growing).
- 85% of bite wounds will yield a positive culture; most are polymicrobial
- Obtain aerobic and anaerobic blood cultures before starting antibiotics if bacteremia is suspected.
- Recent antibiotic therapy may alter culture results.
- Obtain radiograph to check for fractures in clenched-fist injuries.

ALERT
If bite wound is near a bone or joint, obtain a plain radiograph to check for bone injury (baseline imaging is also helpful for later comparison if osteomyelitis is suspected) (2).

**Follow-Up Tests & Special Considerations**
- Plain radiograph and/or magnetic resonance imaging for suspected osteomyelitis.
- Computed tomography scan for severe skull bites. Ultrasound can detect abscess formation.

**Diagnostic Procedures/Other**
Surgical exploration may be needed to determine the extent of injuries or to drain deep infections (e.g., tendon sheath), especially in serious hand wounds.

**Test Interpretation**
Most common microorganisms include:
- Dog bites (3,4)
  - Pasteurella species present in 50% of bites
  - Streptococci spp., Staphylococcus aureus, Staphylococcus intermedius, Neisseria spp.
  - Capnocytophaga canimorsus, Bacteroides spp., Fusobacterium sp.
- Cat bites (4)
  - Pasteurella species in 75% of bites
- Human bites
  - Eikenella corrodens (15–29%), Streptococcus spp., S. aureus (including MRSA), and various anaerobic bacteria (e.g., Fusobacterium, Peptostreptococcus, Prevotella, and Porphyromonas spp.)
  - Although rare, case reports suggest transmission of viruses (hepatitis, HIV, and herpes simplex).
- Reptile bites
  - Pseudomonas aeruginosa, Proteus spp., Salmonella, Bacteroides fragilis, and Clostridium spp.
- Rodent bites
  - Streptobacillus moniliformis or Spirillum minus, which causes rat-bite fever
- Monkey bites
  - All monkey bites can transmit rabies, and bites of a macaque monkey may transmit herpes B virus, which is potentially fatal.
- Ungulate (hooved animals) bites
  - Pigs are the most likely to bite; commonly polymicrobial infections (Staphylococcus and Streptococcus spp., Haemophilus influenzae, Pasteurella, Actinobacillus and Flavobacterium species)
  - Other ungulates are more likely to cause injury by kicking or crushing.

**ALERT**
Asplenic patients and those with underlying hepatic disease are at risk for bacteremia and fatal sepsis after dog bites infected with C. canimorsus.
TREATMENT

GENERAL MEASURES
- Complete and submit bite report per local policy.
- Elevate the injured extremity to prevent swelling.
- Contact local health department to determine rabies prevalence in biting species.
- Snake bite: If venomous, transport for appropriate evaluation and antivenom. Be sure patient is stable for transport; assess coagulation and renal status.

MEDICATION
- Determine need for antirabies therapy: rabies immunoglobulin and human diploid cell rabies vaccine for those bitten by wild animals (primary vector in the United States is bat or raccoon), rabid pets, unvaccinated pets, or in situations where the animal cannot be quarantined for 10 days.

ALERT
Refer to state and local health authorities for rabies consultation (https://www.cdc.gov/rabies/resources/contacts.html).

- Tetanus toxoid (Td) for previously immunized with >10 years since their last dose (2)[C]; tetanus, diphtheria, and pertussis (Tdap) formulation is generally preferred to Td (2)[C]
- Anti-HBs negative patients bitten by HBsAg-positive individuals should receive both hepatitis B immunoglobulin (HBIG) and hepatitis B vaccine.
- HIV postexposure prophylaxis is generally not recommended for human bites, unless there is significant blood exposure to broken skin.
- Monkey bite: Contact CDC, consider an antiviral, such as valacyclovir, active against herpes B virus.
- Preemptive antibiotics recommended only for human bites and high-risk wounds (deep puncture, crush injury, venous or lymphatic compromise, hands or near joint, face or genital area, immunocompromised hosts, requiring surgical repair, asplenic, advanced liver, edema)
- Duration of antibiotic therapy: preemptive, 3 to 5 days; treatment of cellulitis/skin abscess, 5 to 10 days

ALERT
Consider community-acquired MRSA as possible pathogen (from human skin or colonized pet). If high suspicion, doxycycline or trimethoprim-sulfamethoxazole (TMP-SMX) provide good coverage.

First Line
- For preemptive and empiric treatment, amoxicillin and clavulanate is first-line antibiotic (2) [B].
  - Adults: amoxicillin and clavulanate 875/125 mg PO BID
  - Children: <3 months: 30 mg/kg/day PO q12h; ≥3 months and <40 kg: 25 to 45 mg/kg/day q12h; >40 kg: use adult dosing
- Patients with deep or severe wound infections, systemic infections requiring IV therapy, and the immunocompromised:
  - Adults: ampicillin and sulbactam 1.5 to 3.0 g IV q6h or piperacillin and tazobactam 3.375 g
IV q6h (2).
- Children: ampicillin and sulbactam 200 mg/kg/day (dosed on ampicillin component) IV given in 4 divided doses to maximum of 3 g per dose

Second Line
- Alternative oral regimens
  - Adults: clindamycin (300 mg PO TID) plus either TMP-SMX (1 DS tablet PO BID) or ciprofloxacin (500 to 750 mg PO BID)
  - Children: clindamycin 25 to 30 mg/kg/day PO in 3 divided doses to a maximum of 300 mg per dose plus TMP-SMX (8 to 10 mg/kg/day of trimethoprim) PO in 2 divided doses
- Avoid 1st-generation cephalosporins (e.g., cephalexin), penicillinase-resistant penicillins (e.g., dicloxacillin), macrolides (e.g., erythromycin), and clindamycin (when not administered with another agent) because they lack activity against Pasteurella multocida (dog/cat bites) and Eikenella corrodens (human bites).
- Alternative intravenous regimens
  - Adults: ciprofloxacin 400 mg IV q12h or levofloxacin 750 mg IV every day with metronidazole 500 mg IV q8h

Pediatric Considerations
- Pregnant women who cannot take penicillins or cephalosporin due to severe allergy
  - Azithromycin
- Observe closely and note potential increased risk of treatment failure.

ISSUES FOR REFERRAL
- Deep wounds to the hand and face should be referred to a hand surgeon or plastic surgeon.
- Bites from primates or unusual species of animals should be referred to infectious disease specialist.

SURGERY/OTHER PROCEDURES
- Copious irrigation of the wound with normal saline via a catheter tip to reduce risk of infection
- Débridement of puncture wounds is not advised.
- Consider primary closure if the wound is clean after irrigation, the bite is <12 hours old, and in bites to the face (cosmesis).
- Infected wounds and those at high risk for infection (cat bites, human bites, bites to the hand, crush injuries, presentation >12 hours from injury) should be left open.
- Delayed primary closure in 3 to 5 days is an option for infected wounds.
- Splint injured hand.
- Large, gaping wounds should be reapproximated with widely spaced sutures or adhesive strips.
- Consider surgical consultation for deep, severe, or complex bite wounds; bites to vital structures should be treated as possible penetrating traumatic injuries.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients with deep or severe wound infections, systemic infections requiring IV therapy, and the immunocompromised generally require inpatient admission.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Recheck for infection in 24 to 48 hours.
- Daily follow-up for infections to ensure resolution
- Base revisions of antibiotic therapy on culture results and clinical response.

PATIENT EDUCATION
Educate patients about how to avoid animal bites.

PROGNOSIS
Wounds should improve and close over 7 to 10 days.

COMPLICATIONS
- Septic arthritis
- Osteomyelitis
- Extensive soft tissue injuries with scarring
- Hemorrhage
- Gas gangrene
- Sepsis
- Meningitis
- Endocarditis
- Posttraumatic stress disorder
- Death

CODES

ICD10

- S61.459A Open bite of unspecified hand, initial encounter
- S01.85XA Open bite of other part of head, initial encounter
- S20.97XA Other superficial bite of unspecified parts of thorax, initial encounter

CLINICAL PEARLS

- Dog bites are the most common.
- Cleanse, débride, and culture if any signs of infection.
- Antibiotic prophylaxis is recommended for human bites and high-risk wounds.
- Consider rabies and tetanus vaccination.
- Adjust antibiotic choice and duration of therapy based on culture results and clinical improvement.
- Animal and human bites require close follow-up to monitor for infection.
**BASICS**

**DESCRIPTION**
- Primary malignant neoplasms arising in the urinary bladder
- Most common type is transitional cell carcinoma (90%).
- Other types include adenocarcinoma, small cell carcinoma, and squamous cell carcinoma.
- Rhabdomyosarcoma of the bladder may occur in children.

**EPIDEMIOLOGY**

**Incidence**
- Increases with age (median age at diagnosis is 73 years) (1)
- More common in Caucasians than in Asians or African Americans
- Male > female (4:1); but in smokers, risk is 1:1.
- 35.2/100,000 men per year (1)
- 8.7/100,000 women per year (1)
- 20.1/100,000 men and women per year (1)

**Prevalence**
In 2016, 699,450 cases in the United States (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**

Unknown, other than related to risk factors:
- 70–80% is nonmuscle invasive (in lamina propria or mucosa):
  - Usually highly differentiated with long survival
  - Initial event seems to be the activation of an oncogene on chromosome 9 in superficial cancers.
- 20% of tumors are muscle invasive (deeper than lamina propria) at presentation:
  - Tend to be high grade with worse prognosis
  - Associated with other chromosome deletions

**Genetics**
Hereditary transmission is unlikely, although transitional cell carcinoma pathophysiology is related to oncogenes. The GSTM1-null genotype may be associated with increased risk.

**RISK FACTORS**
- Smoking is the single greatest risk factor (increases risk 4-fold) and increases risk equally for men and women (2).
- Use of pioglitazone for >1 year may be associated with an increased risk of bladder cancer. The risk seems to increase with duration of therapy and may also be present with other thiazolidinediones.
- Other risk factors:
  - Occupational carcinogens in dye, rubber, paint, plastics, metal, carbon black dust, and automotive exhaust
- Schistosomiasis in Mediterranean (squamous cell) cancer
- Arsenic in well water
- History of pelvic irradiation
- Chronic lower urinary tract infection (UTI)
- Chronic indwelling urinary catheter
- Cyclophosphamide exposure
- High-fat diet
- Coffee consumption associated with reduced risk (RR 0.83; 95% CI 0.73–0.94)

**ALERT**

Any patient who smokes and presents with microscopic or gross hematuria or irritative voiding symptoms such as urgency and frequency not clearly due to UTI should be evaluated by cystoscopy for the presence of a bladder neoplasm.

**GENERAL PREVENTION**

- Avoid smoking and other risk factors.
- Counseling of individuals with occupational exposure
- The U.S. Preventive Services Task Force has concluded that there is insufficient evidence to determine the balance between risk and harm of screening for bladder cancer (3).

**COMMONLY ASSOCIATED CONDITIONS**

Smoking

**DIAGNOSIS**

**HISTORY**

- Painless hematuria is the most common symptom.
- Urinary symptoms (frequency, urgency)
- Abdominal or pelvic pain in advanced disease
- Exposures (see “Risk Factors”)

**PHYSICAL EXAM**

Normal in early cases, pelvic or abdominal mass in advanced disease, wasting in systemic disease

**DIFFERENTIAL DIAGNOSIS**

- Other urinary tract neoplasms
- UTI
- Prostatism
- Bladder instability
- Interstitial cystitis
- Urolithiasis
- Interstitial nephritis
- Papillary urothelial hyperplasia

**DIAGNOSTIC TESTS & INTERPRETATION**

Initial Tests (lab, imaging)
Urinalysis is the initial test in patients presenting with gross hematuria or urinary symptoms such as frequency, urgency, and dysuria.

- Urine cytology (Consult your local lab for volume needed and proper fixative/handling.)
- Cystoscopy with biopsy is the gold standard for at-risk patients with painless hematuria.
- Computed tomography (CT) or magnetic resonance imaging (MRI) prior to resection of suspected muscle-invasive cancer may be helpful in staging.
- Macroscopic hematuria (55% sensitivity, positive predictive value [PPV] 0.22 for urologic cancer)

**Follow-Up Tests & Special Considerations**

- Urine cytology: 54% sensitivity overall (lower in less advanced tumors), 94% specific
- Other urine markers (of little clinical benefit):
  - Nuclear matrix protein-22 (NMP22): 67% sensitive, 78% specific
  - Bladder tumor–associated antigen stat (BTA-stat): 70% sensitive, 75% specific, may be falsely positive in inflammatory conditions
  - Fluorescence in situ hybridization (FISH) assay: 69% sensitive, 78% specific (PPV 27.1, negative predictive value 95.3) for all tumors, more sensitive and specific for higher grade
  - FGFR3 mutation has high specificity (99.9%) but low sensitivity (34.5%); PPV 95.2%
- Bottom line: None of the urine markers is sensitive enough to rule out bladder cancer on its own.
- Liver function tests, alkaline phosphatase if metastasis suspected
- Done for staging and to evaluate extent of disease but not for diagnosis itself:
  - CT urogram replacing intravenous pyelogram to image upper tracts if there is a suspicion of disease there
  - Diffusion-weighted MRI and multidimensional CT scan are undergoing study for use in diagnosis and staging of bladder tumors.
  - For invasive disease, metastatic workup should include chest x-ray.
  - Bone scan should be performed if the patient has bone pain or if alkaline phosphatase is elevated.
- Urologic CT scan (abdomen, pelvis, with and without contrast) or MRI (40–98% accurate), with MRI slightly more accurate, is recommended if metastasis is suspected.
- Regular cystoscopy (initiated at 3 months postprocedure) is indicated after transurethral resection of bladder tumor (TURBT) and intravesical chemotherapy for superficial bladder cancers. Urinary biomarkers should not be routinely used for follow-up.

**Diagnostic Procedures/Other**

- Cystoscopy with biopsy is the gold standard for diagnosis, but one study showed that 33% of patients had residual tumor after TURBT.

Using photodynamic diagnosis (PDD; employing a photosensitizing agent in the bladder that is taken up by tumor cells and visualized using a particular wavelength of light, which is changed to a different wavelength by the photosensitizing agent) has been shown to increase detection and identification of cancerous superficial tumors when compared with plain white light cystoscopy. A recent meta-analysis shows that this increases the likelihood of total resection.

**Test Interpretation**

- Characterized as superficial (nonmuscle invasive) or invasive (muscle invasive)
- 70–80% present as superficial lesion.
- Superficial lesions
  - Carcinoma in situ: flat lesion, high grade
  - Ta: noninvasive papillary carcinoma
  - T1: extends into submucosa, lamina propria
- Invasive cancer
  - T2: invasion into muscle
    - pT2a: invasion into superficial muscle
    - pT2b: invasion into deep muscle
  - T3: invasion into periavesical fat
    - pT3a: microscopic
    - pT3b: macroscopic
  - T4: invasion into adjacent organs
    - aT4a: invades prostate, uterus, or vagina
    - aT4b: invades abdominal or pelvic wall
- N1–N3: invades lymph nodes
- M: metastasis to bone or soft tissue

**TREATMENT**

For non–muscle-invasive bladder cancer, the treatment is generally removal via cystoscopic surgery (see earlier discussion on PDD). For muscle-invasive cancer, a radical cystectomy with pelvic lymphadenectomy is preferred. A recent Cochrane review compared open radical cystectomy with robotic radical cystectomy, and did not find significant differences in time to recurrence, rates of major complications, quality of life, or positive margin rates.

**MEDICATION**

**First Line**
- A recent meta-analysis demonstrated neoadjuvant chemotherapy using platinum-based combination chemotherapy (with ≥1 of doxorubicin/epirubicin, methotrexate, or vinblastine), but not platinum alone, confers a significant survival advantage in patients with invasive bladder cancer, with an increase in survival at 5 years from 45% (without neoadjuvant treatment) to 50% (with treatment) (combined hazard ratio 0.86; 95% CI 0.77–0.95).
- Intravesical bacillus Calmette-Guérin (BCG) after TURBT in high-grade lesions has been shown to decrease recurrence in Ta and T1 tumors [4][A]. There have been recent shortages in supply of BCG, and gemcitabine may be used as a substitute, but efficacy is not as great as with BCG. Urinary biomarkers may have some utility in tracking response to BCG.

**Second Line**
- Chemotherapy is the first-line treatment for metastatic bladder cancer:
  - Methotrexate, vinblastine, doxorubicin, cisplatin is the preferred regimen.
- A recent review showed that gemcitabine plus cisplatin may be better tolerated and result in equivalent survival to methotrexate, vinblastine, doxorubicin, cisplatin, making it a possible first choice in metastatic bladder cancer.

**ISSUES FOR REFERRAL**

Patients with microscopic or gross hematuria not otherwise explained or resolving should be referred to a urologist for cystoscopy.
ADDITIONAL THERAPIES
Radiotherapy:
- In the United States, used for patients with muscle-invasive cancer who are not surgical candidates
- Preoperative (radical cystectomy) radiotherapy also an option
- Treatment of choice for muscle-invasive cancer in some European and Canadian centers:
  - 65 to 70 Gy over 6 to 7 weeks is standard.

SURGERY/OTHER PROCEDURES
- Surgery is definitive therapy for superficial and invasive cancer:
  - Superficial cancer: TURBT sometimes followed by intravesical therapy
- Invasive cancer
  - Radical cystectomy for invasive disease that is confined to the bladder is more effective than radical radiotherapy. There is insufficient evidence to recommend one form of urinary diversion over another (5).
  - Currently under trial is a trimodal therapy implementing transurethral resection, radiotherapy, and radiosensitizing chemotherapy (6).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Need for surgery or intensive therapy

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Superficial cancers
  - Urine cytology alone has not been shown to be sufficient for follow-up.
  - Cystoscopy every 3 months for 18 to 24 months, every 6 months for the next 2 years and then annually
- Follow-up for invasive cancers depends on the approach to treatment.
- Patients treated with BCG require lifelong follow-up.

DIET
Continue adequate fluid intake.

PATIENT EDUCATION
Smoking cessation

PROGNOSIS
- 5-year relative survival rates (7)
  - Overall survival: 77.3%
    - In situ: 95.7%
    - Localized: 70.1%
    - Regional metastasis: 35.2%
    - Distant metastasis: 5.0%
- Superficial bladder cancer
  - BCG treatment prevents recurrence versus TURBT alone; difference 30%, NNT 3.3
  - BCG prevents progression versus TURBT alone; difference 8%
- Invasive cancer
  - T2 disease: Radical cystectomy results in 60–75% 5-year survival.
  - T3 or T4 disease: Radical cystectomy results in 20–40% 5-year survival.
  - Neoadjuvant chemotherapy with cystectomy has led to varying degrees of increased survival.
  - Radiation with chemotherapy has led to varying degrees of increased survival.
- Metastatic cancer:
  - Methotrexate, vinblastine, doxorubicin, cisplatin resulted in mean survival of 12.5 months.

COMPLICATIONS
- Superficial bladder cancer
  - Local symptoms
    - Dysuria, frequency, nocturia, pain, passing debris in urine
    - Bacterial cystitis
    - Perforation
  - General symptoms
    - Flulike symptoms
    - Systemic infection
- Invasive cancer
  - Symptoms related to definitive treatment, including incontinence, bleeding
  - Patients with neobladder at risk for azotemia and metabolic acidosis

SEE ALSO
- Hematuria
- Algorithm: Hematuria

CODES

ICD10
- C67.8 Malignant neoplasm of overlapping sites of bladder
- C67 Malignant neoplasm of bladder
- C67.6 Malignant neoplasm of ureteric orifice

CLINICAL PEARLS
- Painless hematuria should be evaluated with cystoscopy.
- Be aware of potential link between pioglitazone treatment and risk for bladder cancer.
- The U.S. Preventive Services Task Force recommends against routine screening for bladder cancer.
BORDERLINE PERSONALITY DISORDER
William G. Elder, PhD

BASICS

DESCRIPTION
A psychiatric disorder that begins no later than adolescence or early adulthood, borderline personality disorder (BPD) is a consistent and pervasive pattern of unstable and reactive moods and sense of self, impulsivity, and volatile interpersonal relationships (1):

- Common behaviors and variations:
  - Unstable self-image
  - Unstable goals, aspirations, values, and plans
  - Self-mutilation: pinching, scratching, cutting
  - Suicide: ideation, history of attempts, plans
  - Splitting: idealizing then devaluing others
  - Presentation of helplessness or victimization
  - High utilization of emergency department and resultant inpatient hospitalizations for psychiatric treatment
- High rate of associated mental disorders
- Typically display little insight into behavior

Geriatric Considerations
Illness (both acute and chronic) may exacerbate BPD and may lead to intense feelings of fear and helplessness.

Pediatric Considerations
Diagnosis is rarely made in children. Axis I disorders and general medical conditions (GMCs) are more probable.

Pregnancy Considerations
Physical, emotional, and social concerns may transiently mimic symptoms of BPD: Consider delay in diagnosis until pregnancy completed. Pregnancy may also induce stress or increase fears, resulting in escalation of borderline behaviors.

EPIDEMIOLOGY
Predominant age: onset no later than adolescence or early adulthood (may go undiagnosed for years)

Prevalence
- General population: 0.5–5.9% of U.S. population
- May be overrepresented in primary care
- 10% of all psychiatric outpatients and between 15% and 25% of patients in psychiatry inpatient settings have BPD (2).

ETIOLOGY AND PATHOPHYSIOLOGY
Undetermined but generally accepted that BPD is due to a combination of the following:
- Hereditary temperamental traits
Environment (i.e., history of childhood sexual and/or physical abuse, history of childhood neglect, ongoing conflict in home)

Neurobiologic research suggests that stress exerts damaging effects on the brain, specifically the hippocampus (2). Other findings demonstrate heightened activity in brain circuits involved in the experience of negative emotions and reduced activation that normally suppresses negative emotion once it is generated.

**Genetics**

First-degree relatives are at greater risk for this disorder (undetermined if due to genetic or psychosocial factors).

**RISK FACTORS**

- Genetic factors contribute; however, no specific genes have yet been identified.
- Childhood sexual and/or physical abuse and neglect
- Disrupted family life
- Physical illness and external social factors may exacerbate BPD.

**GENERAL PREVENTION**

- Tends to be a multigenerational problem
- Children, caregivers, and significant others should have some time and activities away from the borderline individual, which may protect them.

**COMMONLY ASSOCIATED CONDITIONS**

Other psychiatric disorders, including:

- Co-occurring personality disorders, frequent
- Mood disorders, common
- Anxiety disorders, common
- Substance-related disorders, common
- Eating disorders, common
- Posttraumatic stress disorder, common
- BPD does not appear to be independently associated with increased risk of violence.

**DIAGNOSIS**

- The comprehensive evaluation should identify
  - Comorbid conditions
  - Functional impairments
  - Adaptive/maladaptive coping styles
  - Psychosocial stressors
  - Patient strengths; needs/goals
- Initial assessment should focus on risk factors:
  - Establish treatment agreement with patient and outline treatment goals.
  - Assess suicide ideation and self-harm behavior.
  - Assess for psychosis.
  - Hospitalization is necessary if patient presents a threat of harm to self or others.

**HISTORY**

- Clinic visits for problems that do not have biologic findings
Conflicts with medical staff members
Idealizing or unexplained anger at physician
History of unrealistic expectations of physician (e.g., “I know you can take care of me.” “You’re the best, unlike my last provider.”)
Obtain collateral information (i.e., from family, partner) about patient behaviors.
History of interpersonal difficulties, affective instability, and impulsivity
History of self-injurious behavior, possibly with suicidal threats or attempts

PHYSICAL EXAM
BPD patients should have a thorough physical examination to help lower suspicion of organic disease (especially thyroid disease) (1,2).
Often, physical examination reveals no gross abnormalities other than related to scarring from self-mutilation.

DIFFERENTIAL DIAGNOSIS
Mood disorders:
– Look at baseline behaviors when considering BPD versus mood disorder.
– BPD symptoms increase the likelihood of misdiagnosing bipolar disorder.
– In particular, disruptive mood dysregulation disorder, a new diagnosis appearing in Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) and characterized by severe recurrent temper outbursts manifesting verbally or behaviorally and grossly out of proportion to the situation, may appear quite similar to the acting out and intense emotions seen in BPD. Look for other symptoms characteristic of BPD to differentiate (1).
Psychotic disorder:
– With BPD, typically only occurs under intense stress and is characterized as “micropsychotic”
Other personality disorder (PD):
– Thoughts, feelings, and behavior will differentiate BPD from other PDs.
GMCs:
– Traits may emerge due to the effect of a GMC on the central nervous system (CNS).
Substance use

DIAGNOSTIC TESTS & INTERPRETATION
Consider age of onset. To meet criteria for BPD, borderline pattern will be present from adolescence or early adulthood.
Formal psychological testing
Rule out personality change due to a GMC (1)[C]:
– Traits may emerge due to the effect of a GMC on the CNS.
Rule out symptoms related to substance use.
If symptoms begin later than early adulthood or are related to trauma (e.g., after a head injury), a GMC, or substance use, then consider other diagnoses.

Diagnostic Procedures/Other
According to DSM-5 criteria, patient must meet at least five of the following criteria (1)[C]:
Attempt to avoid abandonment
Volatile interpersonal relationships
Identity disturbance
• Impulsive behavior:
  – In ≥2 areas
  – Impulsive behavior is self-damaging.
• Suicidal or self-mutilating behavior
• Mood instability
• Feeling empty
• Is unable to control anger or finds it difficult
• Paranoid or dissociative when under stress

With advent of DSM-5, an alternative model is being promulgated that may come to define the diagnosis as impairments in personality functioning and the presence of pathologic traits. Attention to these features may ultimately enhance provider understanding, diagnosis, and treatment of patients with personality dysfunction.
  – Criteria regarding personality functioning refer to impairments of self-functioning (i.e., identity or self-direction) and interpersonal functioning (i.e., empathy or intimacy).
  – Pathologic personality traits refer to characteristics in the domains of negative affectivity (i.e., emotional liability, anxiousness, separation insecurity, depressivity), disinhibition (i.e., impulsivity, risk taking), OR antagonism (1).

### TREATMENT

• Outpatient psychotherapy for BPD is the preferred treatment (3)[A]:
  – Dialectical behavior therapy (DBT) combines cognitive behavioral techniques for emotional regulation and reality testing with concepts of distress tolerance, acceptance, and self-awareness.
  - Following a dialectal process, therapists are tough-minded allies, who validate feelings and are unconditionally accepting while also reminding patients to accept their dire level of emotional dysfunction and to apply better alternative behaviors.
  - DBT may be done individually and in groups.
• Also consider transference-focused (psychodynamic) psychotherapy
• Mentalization, also known as schema-focused therapy, shows promise as a long-term and comprehensive treatment for BPD with high acceptance and high remission rates. Briefer models of mentalization therapy are under investigation (4)[B].
• Also consider cognitive-behavioral therapy or transference-focused (psychodynamic) psychotherapy.
• Patient may need to be placed on suicide watch.
• Brief inpatient hospitalizations are ineffective in changing Axis II disorder behaviors:
  – Hospitalizations should be limited and of short duration to adjust medications, implement psychotherapy for crisis intervention, and to stabilize patients from psychosocial stressors.
• Extended inpatient hospitalization should be considered for the following reasons:
  – Persistent/severe suicidal ideation or risk to others
  – Comorbid substance use and/or nonadherence to outpatient or partial hospitalization treatments
  – Comorbid Axis I disorders that may increase threat to life for the patient (i.e., eating disorders, mood disorders)

### GENERAL MEASURES
Patients with BPD require more medical care and increased “intentionality” by the provider. Therefore, it is important to be aware of which patients in your practice have BPD and to limit this number if demands exceed practice resources.

Focus on patient management rather than on “fixing” behaviors:
- Schedule consistent appointment follow-ups to relieve patient anxiety.
- Meet with and rely on treatment team to avoid splitting of team by patient and to provide opportunity to discuss patient issues.
- Treatment is usually most effective when both medications and psychotherapy are used simultaneously.

**MEDICATION**

- Although no specific medications are approved by the FDA to treat BPD, American Psychiatric Association (APA) guidelines recommend pharmacotherapy to manage symptoms (2)[A],(5)[B].
- Treat Axis I disorders.
- Consider high rate of self-harm and suicidal behavior when prescribing (2)[A].
- APA guideline recommendations (5)[B]:
  - Affective dysregulation: mood stabilizers, selective serotonin reuptake inhibitors (SSRIs), and monoamine oxidase inhibitors (MAOIs)
  - Impulsive-behavioral control: SSRIs and mood stabilizers
  - Cognitive-perceptual symptoms: antipsychotics on a short-term basis
- With more neurobiologic causes considered in relation to BPD, SSRIs are having a less prominent role with more emphasis on mood stabilizers and atypical antipsychotics, but research is uncertain and inconclusive (5)[B].

**ISSUES FOR REFERRAL**

- If hospitalized, consider for suicide risk, mood or anxiety disorders, or substance-related disorders.
- Urgency for scheduled follow-up depends on community resources (e.g., outpatient day programs for suicidal patients; substance abuse programs):
  - With increased risk for self-harm or self-defeating behaviors and low community resources, the patient can/will have increased need for frequent visits.

**ADDITIONAL THERAPIES**

Consider referring patient for specialized mental health behavioral services, including partial hospital therapy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Omega-3 fatty acid dietary supplementation has shown beneficial effects (2)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Admit for inpatient services immediately in presence of psychosis or threat of injury to self or others; include police, as necessary, for safety measures.

- Assess suicidal ideation.
- Consider trial of antipsychotic medications for psychosis.
- Nurses can be instrumental in managing and calling patients, potentially relieving patient stress.
- Patient should not present risk of harm to self or others and have a safety plan.
Follow-up should be scheduled with a mental health specialist and primary care provider.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Schedule visits that are short, more frequent, and focused to relieve patients’ anxiety about relationships with their physician/provider and to help reduce risk of provider burnout.
- Maintain open lines of communication with mental health professionals providing psychological support.
- Emphasize importance of healthy lifestyle modifications (i.e., exercise, rest, diet).

Patient Monitoring

Monitor for suicidal or other self-harm behaviors.

PATIENT EDUCATION

Include patients in the diagnosis so they can make sense of their disease process and participate in the treatment strategy.

PROGNOSIS

- Borderline behaviors may decrease with age and over time.
- Patients in treatment improve at a rate of 7 times compared with following natural course.
- Treatment is complex and takes time.
- Medical focus includes patient management and caring for medical and Axis I disorders.

REFERENCES

CODES

ICD10
F60.3 Borderline personality disorder

CLINICAL PEARLS
- BPD may be discerned by the impropriety of reactions to situations others find minor.
- View BPD as a chronic condition with waxing and waning features. It is important to adjust medications/treatments as clinically appropriate when symptoms change.
- If there are problems with the patient disrespecting the physician or support staff, clear guidelines should be established with the treatment team and then with the patient.
- When considering terminating care, the patient may improve if empathetically confronted about certain behaviors and is given clear guidelines on how to behave in the clinic. It is the patient’s job to follow the guidelines, and it is you and your team’s job to enforce the guidelines. Designate a case management nurse or well-trained support staff person who can be the primary contact person for the patient.
- Have an agenda when you visit with BPD patients. Be cordial—they deserve the same professionalism any patient gets. Have and identify one to two issues to be discussed per clinic visit. Frequently scheduled visits can help with this.
- Regularly scheduled psychotherapy improves medical care by becoming the “home” for mental health treatment, leaving the physician to focus on the patient’s immediate medical issues.
BRAIN INJURY, TRAUMATIC
James R. Yon, MD ● Christina Colosimo, DO, MS ● Caleb J. Mentzer, DO

BASICS

DESCRIPTION
- Traumatic brain injury (TBI) is defined as an alteration in brain function or other evidence of brain pathology, caused by an external force.
- System(s) affected: neurologic; psychiatric; cardiovascular; endocrine/metabolic; gastrointestinal
- Synonym(s): head injury, concussion

EPIDEMIOLOGY

Incidence
- 69 million individuals worldwide are estimated to sustain a TBI each year.
- 2.5 million ED visits and 288,000 hospitalizations per year
- 56,800 deaths per year; ~30% of all injury-related deaths
- Incidence in males twice that of females with 4-fold risk of fatal trauma

Prevalence
- Predominant age: 0 to 4 years, 15 to 19 years, and >65 years
- Predominant gender: male > female (2:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Falls (40%)
- Motor vehicle accidents (14%)
- Assault (10%)
- Child abuse (24% of TBI age ≤2 years)
- Recreational activities (21% of pediatric TBI, peak seasons spring/summer; peak ages 10 to 14 years)
- Primary insult: direct mechanical damage
- Secondary insult: actuation of complex cellular and molecular cascades that promote cerebral edema, ischemia, and apoptotic cell death

RISK FACTORS
Alcohol and drug use, prior/recurrent head injury, contact sports, seizure disorder, attention deficit hyperactivity disorder, male sex

Geriatric Considerations
Subdural hematomas are common after a fall or blow in elderly; symptoms may be subtle and not present until days after trauma. Many elderly patients are on antiplatelet or anticoagulation therapy.

GENERAL PREVENTION
- Safety education and fall prevention
Seat belts; bicycle and motorcycle helmets
Protective headgear for contact sports

**Pediatric Considerations**
Child abuse: Consider if dropped or fell <4 feet (e.g., off bed, couch), suspicious history, significant injury present, or any retinal hemorrhages.

**DIAGNOSIS**

**HISTORY**
- Loss of consciousness (LOC), headache, vomiting, amnesia, confusion, dizziness, sensitivity to light
- Epidural hemorrhage from blunt trauma: 30% with a “lucid interval” (initial LOC followed by recovery of consciousness and then LOC recurs and persists)

**PHYSICAL EXAM**
- Neurologic and cognitive testing is important.
- Repeat neurologic exams every 30 minutes until 2 hours after Glasgow Coma Scale (GCS) reaches 15, then hourly for 4 hours, and then every 2 hours.
- Evidence of increased intracranial pressure (ICP) (elevated BP, decreased pulse rate, or slow/irregular breathing [Cushing triad]—only 30% have all three)
- Decorticate or decerebrate posturing
- Signs of basilar skull fracture: raccoon eyes, Battle sign, hemotympanum, cerebrospinal fluid (CSF) rhinorrhea or otorrhea

**DIFFERENTIAL DIAGNOSIS**
Other causes of altered mental status (e.g., toxicologic, infectious, metabolic, vascular)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Mild TBI and concussions cognitive screening tests
  - Sports Concussion Assessment Tool 3 (SCAT3)
  - Child SCAT3
  - Concussion Recognition Tool (CRT)
  - Standardized Assessment of Concussion (SAC)
  - King-Devick Test
  - Balance Error Scoring System (BESS)
  - Acute concussion evaluation (Ace)
  - Montreal Cognitive Assessment (MoCA)
  - Mini Mental-State Examination (MMSE)
- Evaluate for coagulopathy.
- Type and screen for possible surgical intervention.
- Perform drug and alcohol screening.
- CT, noncontrast, is the study of choice to review bone windows, tissue windows, and subdural space.
- NEXUS II study demonstrated that if all eight clinical criteria are absent, there is a low likelihood of significant TBI:
– Evidence of significant skull fracture (depressed, basilar, or diastatic)
– Altered level of alertness
– Neurologic deficit
– Persistent vomiting
– Presence of scalp hematoma
– Abnormal behavior
– Coagulopathy
– Age >65 years

Follow-Up Tests & Special Considerations
Blast-related TBI: much higher rates of postconcussive syndrome, posttraumatic stress disorder, depression, and chronic pain. Chronic impairment is strongly correlated with psychological factors; return to battlefield guidelines similar to return to play (RTP) in sports (see “General Measures”)

Pediatric Considerations
- Skull radiographs are not indicated unless abuse is suspected in which case they can detect fractures not seen under CT; no return to activity until they are asymptomatic and return to school should precede return to sport/physical activity (1)[A]
- In 2018, the Center of Disease Control came out with 19 sets of recommendations on diagnosis, prognosis, and management/treatment of pediatric patients with mild TBI (2)[B]. Recommendations address imaging, symptom scales, cognitive testing, and standardized assessment for diagnosis; history and risk factor assessment, monitoring, and counseling for prognosis; and patient/family education, rest, support, return to school, and symptom management for treatment.

Diagnostic Procedures/Other
CSF rhinorrhea
- Contains glucose; nasal mucus does not.
- Check for the double halo sign: If nasal discharge contains CSF and blood, two rings appear when placed on filter paper—a central ring followed by a paler ring.

TREATMENT
GENERAL MEASURES
- Acute management depends on injury severity. Most patients need no interventions.
- Immediate goal: Determine who needs further therapy, imaging studies (CT), and hospitalization to prevent further injury.
- For the mildly injured patient
  – Early education is beneficial for recovery (3)[A].
  – RTP
    - Never RTP on same day.
    - Strict guidelines for graduated return to cognitive and physical activity when there are no evident signs or symptoms (physical, cognitive, emotional, or behavioral) on neuropsychological and clinical evaluation (1)[A]
- For the moderate to severely injured patient
Avoid hypotension or hypoxia. Head injury causes increased ICP secondary to edema, and cerebral perfusion pressure (CPP) should be maintained between 60 and 70 mm Hg (4)[A].

- 30-degree head elevation decreases ICP and improves CPP.
- Hyperventilation (hypocapnia)
  - Use should be limited to patients with impending herniation while preparing for definitive treatment or intraoperatively; risk of worsening cerebral ischemia and organ damage (4).
  - Addition of tromethamine can offset deleterious effects and lead to better outcomes.
- Mild systematic hypothermia lowers ICP but leads to increased rates of pneumonia. Selective brain cooling may also decrease ICP with improved outcomes at 2 years postinjury.

Seizure prophylaxis
- Does not change morbidity or mortality. Consider phenytoin or levetiracetam for 1 week postinjury or longer for patients with early seizures, dural-penetrating injuries, multiple contusions, and/or subdural hematomas requiring evacuation (5)[A].

MEDICATION

First Line

- Pain
  - Pain control is important in patients with a TBI. In individuals who have severe brain injuries and can’t communicate, there are scales such as the Nociception Coma Scale (NCS) that can be used (6).
  - Morphine: 1 to 2 mg IV PRN, with caution, because it can depress mental status, further altering serial neurologic evaluations

ALERT

Bolus doses increase ICP and decrease CPP (7)[A].

- Increased ICP
  - Hypertonic saline: 2 mL/kg IV decreases ICP without adverse hemodynamic status; preferred agent (4,7)[A]
  - Mannitol: 0.25 to 2.00 g/kg (0.25 to 1.00 g/kg in children) given over 30 to 60 minutes in patients with adequate renal function. Prophylactic use is associated with worse outcomes (7)[A].

- Sedation
  - Propofol: preferred due to short duration of action. Avoid high doses to prevent propofol infusion syndrome. When combined with morphine, it can also effectively decrease ICP and decrease use of other meds (7)[A].
  - Midazolam: similar sedating effect to propofol but may cause hypotension (7)[A]

- A systematic review that no one sedative agent is more efficacious than the other for improvement of patient-centered outcomes, intracranial pressure, or cerebral perfusion pressure in critically ill adults with severe traumatic brain injury (8).

- Seizures
  - Phenytoin (Dilantin): 15 mg/kg IV (1 mg/kg/min IV, not to exceed 50 mg/min). Stop infusion if QT interval increases by >50%.

ALERT

Avoid corticosteroid use because it increases mortality rates and risk of developing late seizures
(7)[A]. Avoid barbiturates due to risk of hypotension (7)[A].

**ISSUES FOR REFERRAL**
Consult neurosurgery for:
- All penetrating head trauma
- All abnormal head CTs

**ADDITIONAL THERAPIES**
- Emerging therapies with limited but promising evidence: coma arousal therapy: amantadine, zolpidem, and levodopa/carbidopa; postcoma therapy: bromocriptine
- Mixed results for therapeutic hypothermia with defined physiologic parameters (9)[A]
- Increased evidence for continuous hyperosmolar therapy improving survival (10)[A]

**SURGERY/OTHER PROCEDURES**
- Early evacuation of trauma-related intracranial hematoma decreases mortality especially with GCS <6 and CT evidence of hematoma, cerebral swelling, or herniation.
- Decompressive craniectomy reduces ICP especially when a large bone flap is removed; ONLY for adults and ONLY with GCS >6
- Hyperbaric oxygen temporarily lowers ICP and improves mortality, but evidence is conflicting about outcomes at 6 to 12 months postinjury.
- CSF drainage reduces ICP but has not been demonstrated to have long-term benefit.
- CSF leakage often resolves in 24 hours with bed rest, but if not, may require surgical repair (4)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Music therapy in conjunction with multimodal stimulation improves awareness in comatose TBI patients (9)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Abnormal GCS or CT
- Clinical evidence of basilar skull fracture
- Persistent neurologic deficits (e.g., confusion, somnolence)
- Patient with no competent adult at home for observation
- Possibly admit: LOC, amnesia, patients on anticoagulants with negative CT
- ABCs take priority over head injury.
- C-spine immobilization should be considered in all head trauma.
- Use normal saline for resuscitation fluid.
- Discharge criteria: normal CT with return to normal mental status and responsible adult to observe patient at home (see “Patient Monitoring”)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Schedule regular follow-up within a week to determine return to activities.
- Rehabilitation indicated following a significant acute injury. Set realistic goals.
- For patients on anticoagulants, net benefit to restarting therapy after discharge despite increased bleeding risk
Patient Monitoring
Patient should be discharged to the care of a competent adult with clear instructions on signs and symptoms that warrant immediate evaluation (e.g., changing mental status, worsening headache, focal findings, or any signs of distress). Patients should be monitored but not awakened from sleep.

DIET
As tolerated, monitor for signs of nausea.

PATIENT EDUCATION
Proper counseling, symptomatic management, and gradual return to normal activities are essential.

PROGNOSIS
- Gradual improvement may continue for years.
- 30–50% of severe head injuries may be fatal.
- Predicting outcome is difficult; many with even minor to moderate injuries have moderate to severe disability at 1 year, whereas prolonged coma may be followed by satisfactory outcome.
- Patients may have new-onset seizures over 2 years following trauma.
- Poor prognostic factors: low GCS on admission, nonreactive pupils, old age, comorbidity, midline shift
- 50% of patients with mild TBI will return to work by 1 month after injury, and more than 80% by 6 months.

COMPLICATIONS
- Chronic subdural hematoma, which may follow even “mild” head injury, especially in the elderly; often presents with headache and decreased mentation
- Delayed hematomas and hydrocephalus
- Emotional disturbances and psychiatric disorders resulting from head injury may be refractory to treatment.
- Seizures: seen in 50% of penetrating head injuries, 20% of severe closed head injuries, and <5% of head injuries overall. Hematomas increase risk of epilepsy.
- Postconcussive syndrome can follow mild head injury without LOC and includes headaches, dizziness, fatigue, and subtle cognitive or affective changes.
- Second-impact syndrome occurs when the CNS loses autoregulation. An individual with a minor head injury is returned to a contact sport, and, following even minor trauma (e.g., whiplash), the patient loses consciousness and may quickly herniate, with a 50% mortality. A similar syndrome of malignant edema can occur in children with even a single injury.
- Increased risk for Alzheimer disease, Parkinson disease, and other brain disorders whose prevalence increases with age

REFERENCES
2. Lumba-Brown A, Yeates KO, Sarmiento K, et al. Centers for Disease Control and

CODES

ICD10
- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.5X0A Traum subdr hem w/o loss of consciousness, init
- S06.6X0A Trauma subrac hem w/o loss of consciousness, init

CLINICAL PEARLS

- TBI involves two distinct phases: the primary mechanical insult and secondary dysregulation of the cerebrovascular system with cerebral edema, ischemia, and cell-mediated death.
- Indications for imaging include evidence of skull fracture, altered consciousness, neurologic deficit, persistent vomiting, scalp hematoma, abnormal behavior, coagulopathy, and age >65 years.
BREAST ABSCESS
Kelley V. Lawrence, MD, IBCLC, FAAFP, FABM ● Shannon A. Sanchez Oviedo, MD, MS ● Elizabeth Joyce Trout, MD, MLS

BASICS

DESCRIPTION
● Localized accumulation of infected fluid within the breast parenchyma
● Associated with lactation or fistulous tracts secondary to squamous epithelial neoplasm or duct occlusion
● System(s) affected: skin/exocrine, immune
● Synonym(s): mammary abscess; peripheral breast abscess; subareolar abscess; puerperal abscess

Pregnancy Considerations
Most commonly associated with postpartum lactation

EPIDEMIOLOGY
● Predominantly reproductive age and perimenopausal
  – Puerperal abscess: lactational
  – Subareolar abscess: reproductive age through postmenopause (1)
    o Nipple piercing associated in increased risk of subareolar abscess (2)
    o Smoking linked to recurrences (2)
● Predominant sex: female
● Higher incidence in African American, diabetic, smoking, or obese women (2)

Incidence
● Ranges estimate up to 11% of breastfeeding women; the Academy of Breastfeeding Medicine cites 3% (1,3)
● Puerperal abscess has highest incidence within 12 weeks’ postpartum (2) and while weaning from breastfeeding (3)

Prevalence
Transient condition; recurrences are most strongly associated with smoking, surgical treatment, and increased age (2)

ETIOLOGY AND PATHOPHYSIOLOGY
● Puerperal abscesses:
  – Insufficient treatment of mastitis
  – Unattended postpartum engorgement and other situations leading to breast milk stasis (3)
  – Plugged lactiferous duct causing stasis, leading to microbial growth and secondary abscess formation
● Subareolar abscess:
  – Associated with squamous metaplasia of the lactiferous duct epithelium, keratin plugs, ductal ectasia, fistula formation (1)
  – Higher incidence in patients with nipple piercings (2)
Microbiology
- Staphylococcus aureus is most common cause for lactational abscesses (2,3)
- Methicillin-resistant S. aureus (MRSA) is a significant cause (3)
- Less common causes (2)
  - Streptococcus pyogenes, Escherichia coli, Bacteroides, Corynebacterium, Pseudomonas, Proteus
  - Anaerobes and mixed flora are more common in subareolar abscesses
  - In patients with breast implants, coagulase negative S. aureus is more common
  - In nonlactational abscesses, lack of growth is a common result

Genetics
No current evidence to support a genetic predisposition to breast abscess formation (lifestyle/environment have been implicated more often)

RISK FACTORS
- Maternal age >30 years (4)
- Primiparous (4)
- Gestational age ≥41 weeks (4)
- Puerperal mastitis
  - Up to 11% progression to abscess (2)
  - Most often due to inadequate antibiotic and anti-inflammatory treatment of mastitis (3)
  - Risk factors (stasis) (3):
    - Infrequent or missed feeds
    - Poor latch, weak or uncoordinated suckling
    - Damage or irritation of the nipple
    - Nipple inversion or retraction
    - Inefficient removal of milk (by baby or pump)
    - Oversupply of milk
    - Illness in mother or baby
    - Rapid weaning
    - Plugged duct
    - Pressure on the breast (i.e., tight bra, car seatbelt)
    - Maternal stress and fatigue
- General risk factors (2)
  - Smoking; diabetes; obesity
  - African American
  - Nipple piercing
- Medically related risk factors
  - Steroids
  - Breast implants
  - Lumpectomy with radiation
  - Inadequate antibiotics to treat mastitis
  - Topical antifungal medication used for mastitis

GENERAL PREVENTION
- Frequent breast emptying with on-demand feeding and/or pumping to prevent mastitis
- Early treatment of mastitis with milk expression, antibiotics, and compresses
Smoking cessation to minimize occurrence/recurrence

COMMONLY ASSOCIATED CONDITIONS
Lactation, mastitis, weaning

DIAGNOSIS

HISTORY
- Tender breast lump, usually unilateral
- Breastfeeding, weaning, or returning to work
- Decreased breast milk supply on affected breast
- Perimenopausal/postmenopausal
- Systemic malaise (usually less than with mastitis)
- Localized erythema, edema, pain
- Fever, nausea, vomiting
- Spontaneous nipple drainage
- Prior breast infection
- Diabetes

PHYSICAL EXAM
- Fever, tachycardia (not always present)
- Erythema of overlying skin
- Palpable mass, sometimes fluctuant
- Tenderness on palpation
- Induration
- Local edema
- Draining pus or skin ulceration
- Nipple and/or skin retraction
- Regional lymphadenopathy
- Puerperal abscesses are generally peripheral; nonlactational abscesses are more commonly found in periareolar/subareolar region

DIFFERENTIAL DIAGNOSIS
- Engorgement
- Plugged milk duct
- Mastitis
- Galactocele (sometimes referred to as a milk lake)
- Fibrocystic breasts
- Fat necrosis
- Tuberculosis (may be associated with HIV infection)
- Sarcoid: granulomatous mastitis
- Syphilis
- Foreign body reactions (e.g., to silicone and paraffin)
- Mammary duct ectasia
- Carcinoma (inflammatory or primary squamous cell)

DIAGNOSTIC TESTS & INTERPRETATION
**Initial Tests (lab, imaging)**
- Ultrasound helps identify fluid collection (5)
- Complete blood count (leukocytosis), elevated erythrocyte sedimentation rate
- Culture and sensitivity of expressed breast milk or infected aspirate to identify pathogen

**Follow-Up Tests & Special Considerations**
Mammogram to rule out malignancy (generally not done during acute phase)

**Diagnostic Procedures/Other**
- Aspiration (+/− ultrasound guided) for culture
  - Does not exclude malignancy
  - Cytology (particularly in nonlactating patient)

**Test Interpretation**
- If ultrasound negative for pocket of fluid, consider alternative diagnoses
- Utilize culture sensitivities to guide antibiotic therapy when possible
- If multiloculated on imaging, refer to breast surgical/interventional specialist

---

**TREATMENT**

**GENERAL MEASURES**
- Cold and/or warm compresses for pain control (3)[C]
- Continue to breastfeed or express milk to drain the affected breast (3)[A]
- Antibiotic treatment without puerperal abscess drainage is ineffective (4)[A].
  - Acceptable to start antibiotics while working to get patient to drainage/aspiration

**MEDICATION**
Combination of antibiotics plus drainage for cure

**First Line**
- Please note: in addition to medications detailed here, surgical management is first line (see below)
- Optimal antibiotic first-line treatment for mastitis includes dicloxacillin 500 mg q6h, flucloxacinil 500 mg q6h, or 1st-generation cephalosporin (but may be less preferred due to broader spectrum of coverage); clindamycin if severely penicillin-allergic (3)
- Breast abscess first-line treatment includes empiric antibiotics to cover community-acquired MRSA
  - Nonsevere infection:
    - Clindamycin 300 to 450 mg PO QID as alternative for penicillin-allergic and if concern for anaerobes (1)[C]
    - TMP-SMZ DS 1 to 2 PO BID for 10 to 14 days (3)[C]
    - Dicloxacillin plus metronidazole if nonlactational (2)[B]
  - Contraindications: antibiotic allergy
    - In severe infections, vancomycin as an inpatient may be necessary (6)[C]
      - Dose of vancomycin = (30 mg/kg) IV in 2 divided doses every 24 hours until culture results are available
      - Daptomycin can be used as an alternative to vancomycin due to once daily infusion
(outpatient), allowing breastfeeding mothers to feed and pump frequently at home (6)[C]
- Dose (4 mg/kg) IV every 24 hours may be necessary until culture results are available

Second Line
Consult infectious disease specialist if inadequate response to antibiotic treatment plus drainage

ISSUES FOR REFERRAL
- Patient must be stable for outpatient referral
- If showing signs of hemodynamic instability, patient should be referred for inpatient stabilization and care (rare)

ADDITIONAL THERAPIES
- Nonsteroidal anti-inflammatory drugs for analgesia, anti-inflammatory effect, and/or antipyresis (3)[B]
- Rest, adequate fluid intake, good nutrition (3)[B]
- Application of heat to the breast just prior to feeding/milk-expression may help with adequate milk flow (3)[C]
- Cold packs applied after a feeding/milk-expression can reduce pain and edema (3)[C]

SURGERY/OTHER PROCEDURES
- Drain all abscesses and treat with antibiotics (1)[A]
- Current best practice recommendation suggest
  - Aspiration with or without US guidance for abscesses <3 cm (1)[B] (Serial aspirations may be necessary.)
  - Consider US-guided percutaneous catheter placement if abscess >3 cm (1)[B]
  - Consider incision and drainage (I&D) if abscess is >5 cm, recurrent, or chronic (1)[B]
- Ongoing research indicates that an algorithmic approach may provide more consistent outcomes (7)[C]
  - Consider needle aspiration for abscesses <5cm on US, no skin changes (defined as ulceration, desquamation, or frank extrusion of purulence), and fewer than 5 days of symptoms
  - US-guided aspiration of breast abscess is preferred to I&D in most cases due to better cosmesis and faster recovery (7)[B]
- Ongoing research also investigating use of pigtail catheter insertion and/or vacuum assisted biopsy/aspiration (5)[B]
- Biopsy nonpuerperal abscesses to rule out malignancy; remove all fistulous tracts in nonlactating patients as well (1)[C]

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Lecithin supplementation
- Acupuncture may help with breast engorgement and prevention of breast abscess
- Breast lymphatic massage may ease engorgement
- Judicious use of cabbage leaves applied over affected area (to decrease inflammation and milk production)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient, unless systemically immunocompromised, septic, or requiring inpatient antibiotic treatment
Hospital-grade breast pump should be made available to patient from time of admission

**ONGOING CARE**
- If lactational, continue effective milk removal to prevent recurrence
- If planning to wean from breastfeeding, avoid abrupt discontinuation of feeding
- Consider smoking cessation to decrease risk of nonlactational abscess recurrence

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Ensure complete resolution to exclude malignancy
- Close outpatient follow-up until resolution as abscesses may require serial aspirations or drainage

**DIET**
No dietary patterns have been associated with breast abscess formation

**PATIENT EDUCATION**
- Wound care, rest, breast milk emptying
- Continue with breastfeeding or pumping (if breastfeeding is not possible due to location of abscess; infant mouth not to come in contact with affected tissue) to prevent engorgement

**PROGNOSIS**
- Drained abscess heals from inside out (in 8 to 10 days)
- Subareolar abscesses frequently recur, even after incision and drainage (I&D) and antibiotics; may require surgical removal of ducts

**COMPLICATIONS**
- Fistula: mammary duct or milk fistula
- Poor cosmetic outcome
- Early cessation of breastfeeding (3)

**REFERENCES**

CODES

ICD10
- N61 Inflammatory disorders of breast
- O91.13 Abscess of breast associated with lactation
- O91.12 Abscess of breast associated with the puerperium

CLINICAL PEARLS

- Up to 11% of cases of puerperal mastitis progress to abscess formation (most often due to inadequate therapy).
- Risk factors for mastitis result from milk stasis (poor milk transfer, infrequent feeds, missing feeds, weaning) (1,3).
- Treat abscesses not associated with lactation with antibiotics that cover anaerobic bacteria and work up for malignancy.
- The treatment of choice for most breast abscesses is the combination of antibiotics plus aspiration.
- US-guided aspiration of breast abscess is preferred to I&D in most cases due to better cosmesis and faster recovery (7)[B].
- If lactational, continue to empty the breast (feeding, pumping, or expression of breast milk) (3).
BREAST CANCER
Fairouz L. Chibane, MD • Alicia H. Vinyard, DO

BASICS
Most commonly diagnosed cancer (CA) and the second most common cause of CA death for U.S. women

DESCRIPTION
- Malignant neoplasm of cells native to the breast—epithelial, glandular, or stroma
- Types: ductal carcinoma in situ (DCIS), infiltrating ductal carcinoma, infiltrating lobular carcinoma, Paget disease, phyllodes tumor, inflammatory breast cancer (BC), angiosarcoma
- Molecular subtypes: luminal A (HR+/HER2−), triple negative (HR−/HER2−), luminal B (HR+/HER2+), HER2-enriched (HR−/HER2+)

EPIDEMIOLOGY
Incidence
- Estimated new female BC cases for in situ: 63,410; invasive: 252,710 in 2017
- Estimated new male BC cases: 2,470
- Estimated deaths 2017—females: 40,610; males: 460

Prevalence
>3.5 million U.S. women with a history of BC were alive on January 1, 2016 (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Genes such as BRCA1 and BRCA2 function as tumor suppressor genes, and mutation leads to cell cycle progression and limitations in DNA repair.
- Mutations in estrogen/progesterone induce cyclin D1 and c-Myc expression, leading to cell cycle progression.
- Additional tumors (33%) may cross-talk with estrogen receptors and epidermal growth factors receptors (EGFR), leading to similar abnormal cellular replication.

Genetics
- Criteria for additional risk evaluation/gene testing in affected individual
  - BC at age ≤50 years
  - BC at any age and ≥1 family member with BC ≤50 years of age or ovarian/fallopian tube/primary peritoneal CA any age or ≥2 family members with BC or pancreatic CA any age or population at increased risk (e.g., Ashkenazi Jew with BC or ovarian CA at any age)
  - Triple-negative BC (ER−, PR−, HER2−)
  - Two BC primaries in single patient
  - Ovarian/fallopian tube/primary peritoneal CA
  - 1+ family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, central nervous system (CNS), diffuse gastric, aggressive prostate (Gleason >7), leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, gastrointestinal (GI) hamartomas
  - Male BC
- Known BC susceptibility gene mutation in family

Criteria for additional risk evaluation/gene testing in unaffected BC individual
- First- or second-degree relative with BC ≤45 years of age
- ≥2 breast primaries in one individual or ≥1 ovarian/fallopian tube/primary peritoneal CA from same side of family or ≥2 w/ breast primaries on same side of family
- 1+ family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, CNS, diffuse gastric, aggressive prostate, leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, GI hamartomas
- Ashkenazi Jewish with BC/ovarian CA at any age
- Male BC
- Known BC susceptibility gene mutation in family

BRCA1 and BRCA2 are inherited in an autosomal fashion and account for 5–10% of female and 5–20% male CAs; 15–20% familial BCs
- Mutations higher in Ashkenazi Jewish descent (2%)
- Mutation in BRCA raises risk to 45–65% from 7% at age 70 years.

Other BC associated genes: ATM, BARD1, BRIP, CDH1, PTEN, STK11, CHEK2, p53, ERBB2, DIRAS3, NBN, RAD50, RAD51

Syndromes associated with BC: Cowden syndrome (PTEN), Li-Fraumeni syndrome (TP53), ataxia-telangiectasia (ATM), and Peutz-Jeghers (STK11)

RISK FACTORS
- National Cancer Institute BC Risk calculator: https://bcrisktool.cancer.gov/
- Hormone Replacement Therapy (combination estrogen-progesterone and estrogen-only agents (but not vaginal estrogen) during perimenopause increases breast cancer risk for 10 years after medication is discontinued.
- Relative risk (RR) >4.0: age >65 years, biopsy confirmed atypical hyperplasia, BRCA mutation, DCIS, lobular carcinoma in situ (LCIS), personal history of early onset BC (<40 years), two or more first-degree relatives diagnosed at an early age
- RR 2.1 to 4.0: history of BC (40+ years), postmenopausal, radiation, first-degree relative of BC
- RR 1.1 to 2.0: EtOH, Ashkenazi Jewish, diethylstilbestrol exposure, early menarche (<12 years), late menopause (>55 years), high socioeconomic status, first pregnancy >30 years, proliferative breast disease without atypia (fibroadenoma or ductal hyperplasia), dense breasts (>50%), never breastfed, no full-term pregnancies, obesity, personal history of endometrial or ovarian CA, hormone replacement therapy, recent oral contraceptive pill use, height (tall)
- 20–25% lifetime risk should receive an annual MRI beginning at age 30 years: BRCA mutation, first-degree relative with BRCA mutation, history of radiation age 10 to 30 years, Li-Fraumeni or Cowden syndrome or first-degree relative with the same
- 15–20% lifetime risk: personal history of BC, DCIS, LCIS, atypical ductal hyperplasia, atypical lobular hyperplasia, dense or unevenly dense breasts

GENERAL PREVENTION
- Maintain healthy weight—obesity increases BC risk; physical activity and healthy diet are key.
- Limit EtOH—moderate alcohol use increases risk
- Medication: The U.S. Preventative Services Task Force (USPSTF) recommends that clinicians offer to prescribe risk-reducing medications, such as tamoxifen, raloxifene, or aromatase inhibitors, to women who are at increased risk for breast cancer and at low risk for adverse
medication effects (B recommendation). The National Cancer Institute Risk Assessment Tool can be used to determine risk. “Greater” risk was defined as >3% where the risk of medication harms are low.

- Breast self-exams (BSE): American Cancer Society no longer recommend monthly BSE
- Clinical breast exam (CBE):
  - USPSTF: insufficient evidence to assess clinical benefits and harms
  - American Cancer Society (ACS): no clear benefit or structured guidelines in average-risk women (1)
- Mammography:
  - USPSTF: women biennial mammogram at age 50 to 74 years
  - ACS: women annual mammograms starting at age 45 years and biennial mammograms at 55 (1)

**COMMONLY ASSOCIATED CONDITIONS**

- Obesity
- Genetic syndromes and mutations such as BRCA1, BRCA2, and Li-Fraumeni
- History of high-risk breast lesions such as atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH), and LCIS

**DIAGNOSIS**

**HISTORY**

- Painless lump in breast or axilla, breast pain, heaviness
- Swelling, thickening, redness, or dimpling of the skin (sign of advanced BC)
- Nipple discharge (bloody), erosion, or retraction
- Abnormal findings or calcifications on screening mammography

**PHYSICAL EXAM**

- Visualize breasts with patient sitting and supine for skin dimpling, peau d’orange, asymmetry.
- Palpation of breast and regional lymph node exam: supraclavicular, infraclavicular, axillary

**DIFFERENTIAL DIAGNOSIS**

- Benign breast disease: fibrocystic disease, fibroadenoma, intraductal papilloma (bloody nipple discharge), duct ectasia, cyst, sclerosing adenosis, fat necrosis (serial/parallel [s/p] breast trauma)
- Infection: abscess, cellulitis, mastitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- All newly diagnosed BC should be offered multidisciplinary care: history and physical, pathology review, ER/PR and HER2 status determination, genetic counseling, fertility counseling, and assess for clinically palpable nodes.
- Calcifications on screening mammography needs to be evaluated with diagnostic mammogram (Dx MMG) and stereotactic guided biopsy. Palpable masses on exam should be evaluated with Dx MMG and US ± biopsy.
- Mammography (MMG) BI-RADS: Breast Imaging–Reporting and Data System is a quality assurance (QA) method published by the American Radiology Society. BI-RADS
interpretation: 0: incomplete (need additional imaging); 1: negative; 2: benign; 3: probably benign; 4: suspicious; 5: highly suggestive of malignancy; 6: known biopsy—proven malignancy

- Palpable mass ≥30 years: Obtain Dx MMG and US to determine cystic versus solid.
  - If BI-RADS 1 to 3, then get US ± biopsy.
  - If BI-RADS 4 to 6, then get core needle biopsy ± surgical excision.
- Palpable mass <30 years: Obtain US ± Dx MMG ± biopsy; if low clinical suspicion, may observe for 1 to 2 menstrual cycles for resolution
- Spontaneous, reproducible nipple discharge: Obtain Dx MMG ± US.
  - If negative, then get ductogram or MRI ± surgical excision.
- Asymmetric thickening/nodularity ≥30 years: Obtain Dx MMG+ US ± biopsy.
- Asymmetric thickening/nodularity <30 years: Obtain US ± Dx MMG ± biopsy.
- Skin changes, peau d’orange: Obtain Dx MMG ± US ± biopsy for underlying mass; if no mass, then perform punch biopsy of skin change.
- Palpable lymph nodes: Obtain CT chest, abdomen/pelvis, and bone scan.

Follow-Up Tests & Special Considerations

- Signs and symptoms warrant
- Advanced disease (stage IIIA or higher)
  - Chest diagnostic CT, abdominal ± pelvis CT, FDG positron emission tomography (PET)/CT scan, bone scan or sodium fluoride PET/CT if FDG-PET/CT indeterminate
- Most common metastasis: lungs, liver, bone, brain
- Bone scan: localized pain, elevated alkaline phosphate
- Abdominal ± pelvis CT: abdominal symptoms, elevated alkaline phosphate, abnormal LFTs
- Chest imaging: pulmonary symptoms
- MRI: CNS/spinal cord symptoms

Diagnostic Procedures/Other

- Primary tumor: fine-needle aspiration (FNA), US-guided core needle biopsy, stereotactic-guided core needle biopsy; MRI-guided biopsies for abnormalities only visualized on breast MRI
- Axillary lymph nodes: US of axilla during workup and core-needle biopsy or FNA if suspicious, otherwise, excise during sentinel lymph node biopsy.
- Distant disease on staging scans: Obtain biopsy to confirm metastatic disease.
- Postbiopsy may get inflammatory changes/hematoma/bruising and reactive lymph nodes.

Test Interpretation

- Ductal/lobular/other: tumor size, inflammatory component, invasive/noninvasive, margins, nodal involvement
- Tumor receptor status: ER, PR, HER2 assay. Positive receptor status allows for targeted therapies.

TREATMENT

GENERAL MEASURES

- Multiple treatment modalities surgery, radiation, chemotherapy, and hormone therapy
- National Comprehensive Cancer Network (NCCN) provides clinical treatment guidelines for
MEDICATION

- Neoadjuvant chemotherapy: Premenopausal women should be counseled on potential effect of chemotherapy on fertility; refer to fertility expert.
  - Locally advanced (positive lymph nodes), inoperable advanced BC (stage III)
  - Early operable BC for breast conservation surgery
  - Triple negative BC and tumor size ≥0.5 cm
  - HER2 (+) tumors ≥2 cm
- Consider 21-gene PT-PCR assay in ER/PR(+) tumors with (−) nodes to potentially assess risk of recurrence; not validated to predict chemotherapy response; can determine if chemotherapy indicated in the adjuvant setting
- Cytotoxic therapy: anthracyclines, taxanes, alkylating agents, antimetabolites
  - Higher risk patients with nonmetastatic operable tumors
  - Patients with high risk of recurrence after local treatment (s/p surgery ± radiation)
- Dose-dense chemotherapy demonstrates overall survival advantage in early BC.
  - Doxorubicin/cyclophosphamide (AC) weekly or every 2 weeks paclitaxel for HER2-negative BC
- Anti-HER2/neu antibody (e.g., trastuzumab with or without pertuzumab) in HER2/neu-positive patients; given with other chemotherapy agents in the neoadjuvant or adjuvant setting

ISSUES FOR REFERRAL

Medical oncology referral for chemotherapy side effects (i.e., neutropenic fevers, neuropathy)
- Cardiology referral for trastuzumab induced cardiomyopathy

ADDITIONAL THERAPIES

- Radiation Therapy (RT)
  - Upon completion of surgery ± chemotherapy, whole breast radiation should be offered for patients undergoing breast conservation therapy (BCT) prior to starting endocrine therapy.
  - Mastectomy alone versus lumpectomy + RT overall survival is similar.
  - Postmastectomy RT is offered if tumor >5 cm, ≥4 lymph nodes are involved, chest wall/skin involvement, unable to obtain clear margins.
  - Side effects may include skin hyperpigmentation, skin thickening/fibrosis, loss of breast volume, and chronic pain.
- Secondary prevention
  - ASA once per week
- General prevention for high risk lesions (LCIS, ALH, ADH)
  - Tamoxifen 10 mg QOD for 3 years
- Hormone therapy for ER+ tumors
  - DCIS:
    - Tamoxifen 10 mg QOD for 3 years
    - Age <60 and postmenopausal: may use aromatase inhibitors (AI)
    - Age >60: selective estrogen receptor modulator (SERM) or AI equally effective
  - Invasive cancer:
    - SERM (tamoxifen 20 mg QD, raloxifene 60 mg QD, and toremifene 60 mg QD): premenopausal at diagnosis: 5-year treatment and consider for additional 5 years; avoid during lactation, pregnancy, or with history of deep venous thrombosis/pulmonary
embolism.
  o Aromatase inhibitors (anastrozole 1 mg QD, letrozole 2.5 mg QD, and exemestane 25 mg QD): postmenopausal women, 5-year treatment following endocrine therapy for 4.5 to 6 years, or endocrine therapy for up to 10 years
  o Ovarian ablation or suppression with luteinizing hormone–releasing hormone agonists: premenopausal women

**Advanced disease**
- Hormone therapy and cytotoxic therapy
- Bisphosphonates skeletal complications
- Antivascular endothelial growth factor antibody
- Anti-HER2/neu antibody in select HER2/neu-positive patients

**Pregnancy Considerations**
- Treatment varies on trimester.
- Surgical: mastectomy or breast conservation: mastectomy preferred due to limitations of radiation during pregnancy. BCT can be offered in 3rd trimester.
- Sentinel lymph node biopsy (SLNB): safe to use with lymphoscintigraphy
- Chemotherapy: appropriate in 2nd and 3rd trimesters; trastuzumab contraindicated
- RT: Avoid until after delivery.

**SURGERY/OTHER PROCEDURES**
- Breast-conserving therapy (lumpectomy) offered if negative margins can be achieved and the patient will also receive adjuvant RT
- Mastectomy indicated for multifocal disease, large tumor to breast size ratio, inflammatory BC, T_4_ disease, contraindication to RT, patient preference
- Evaluation of axillary nodes: preop US and biopsy for all patients with clinically suspicious axillary nodes. If biopsy is positive, an axillary node dissection should be performed. If negative, an SLNB at the time of surgery should be performed.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Mastectomy
  - Complications: seroma, hematoma, cellulitis, chest wall/axilla/arm pain
- Axillary dissection
  - Complications: lymphedema—avoid having BP and blood draws/IV taken on side of surgery
  - Occupational therapist pre/postop for exercises to improve ROM and strategies to reduce lymphedema

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Every 4 to 6 months for 5 years and then annually
- No evidence to support the use of routine complete blood count, LFTs, “tumor markers,” bone scan, chest x-ray, liver US, CT scans, MRI, PET
- Mammogram 6 postradiation then annually
- Annual gynecologic exam on endocrine therapy; bone mineral density at baseline and follow-
DIET
Active lifestyle, healthy diet, limited alcohol intake

PROGNOSIS
5-year survival (SEER 18, all races, females)
- Localized 98.8%
- Regional 85.5%
- Distant 27.4%
- Unknown 54.5%
- All stages 89.9%

COMPLICATIONS
- Surgery: lymphedema, wound infections, seroma, hematoma, chronic pain, limited range of motion, poor cosmesis
- Chemotherapy: immunosuppression, neuropathy, cardiotoxicity
- Radiation: skin breakdown, fibrosis, chronic pain, long-term increased risk of sarcoma
- Endocrine therapy: osteoporosis, endometrial cancer, and deep venous thrombosis

REFERENCE

CODES
ICD10
- C50.52 Malignant neoplasm of lower-outer quadrant of breast, male
- C50.929 Malignant neoplasm of unspecified site of unspecified male breast
- C50.812 Malignant neoplasm of overlapping sites of left female breast

CLINICAL PEARLS
- U.S. women; lifetime risk of 1 in 8
- High alcohol use, high body mass index (BMI), and physical inactivity are modifiable risk factors.
- Normal mammography does not exclude possibility of CA with a palpable mass.
BREASTFEEDING
Ronald G. Chambers Jr., MD, FAAFP • Angelia Leipelt, BA, IBCLC, ICCE, CLE

BASICS
• Breastfeeding is the natural process of feeding human milk directly from the breast.
• Breast milk is the preferred nutritional source and the normal and physiologic way to feed all newborns and infants.
• Breast milk contains over 200 active components that provide nutrition, fight pathogens, promote healthy gut microbiome, and aid in maturity of immune system.
• The American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), American Congress of Obstetricians and Gynecologists (ACOG), World Health Organization, and other medical organizations recommend exclusive breastfeeding for 6 months, with continuation of breastfeeding for ≥1 year as desired by mother and infant (1)[A].

DESCRIPTION
• Maternal benefits (as compared with mothers who do not breastfeed) include the following:
  – Rapid involution/decreased postpartum bleeding (due to oxytocin release)
  – Association of decreased risk of postpartum depression and increased bonding
  – Associated postpartum weight loss
  – Decreased risk of breast cancer and association of decreased risk of pre- and postmenopausal ovarian cancer, decreased risk of type 2 diabetes, hypertension, hyperlipidemia, rheumatoid arthritis, and cardiovascular disease
  – Decreased risk of prematurity due to child spacing
  – Increased bone density
  – Convenience and economic savings
  – Association of longer continuation in work/school activities
• Infant benefits (as compared with children who are formula-fed) include the following (1):
  – Ideal food: easily digestible, nutrients well absorbed, less constipation
  – Lower rates of virtually all infections via maternal antibody protection
    o Fewer respiratory and GI infections
    o Decreased incidence of otitis media
    o Decreased risk of bacterial meningitis, pneumonia, and sepsis
    o Decreased incidence of necrotizing enterocolitis
    o Decreased risk of ear infections
  – Decreased incidence of obesity and type 1 and 2 diabetes
  – Decreased incidence of allergies, clinical asthma, and atopic dermatitis in childhood
  – Decreased risk of developing celiac disease and inflammatory bowel disease
  – Decreased risk of childhood leukemia
  – Decreased risk of sudden infant death syndrome (SIDS) and decreased mortality
  – Enhanced neurodevelopmental performance
  – Increased attachment between mother and baby
  – Decreased child abuse
  – Decreases the risk of urinary tract infection
EPIDEMIOLOGY

Incidence

- According to CDC’s Breastfeeding Scorecard, U.S. breastfeeding rates are on the rise in 2018:
  - any breastfeeding: 83.2% (however, differs among different sociodemographic and culture) (2)
  - Breastfeeding at 6 months: 57.6%
  - Breastfeeding at 12 months: 35.9%
  - Exclusive breastfeeding at 3 months: 46.9%
  - Exclusive breastfeeding at 6 months: 24.9%

ETIOLOGY AND PATHOPHYSIOLOGY

- The mechanism of milk production is based on several hormones: Prolactin triggers milk production and oxytocin releases milk based on supply and demand (3). Endocrine control system triggers making of colostrum at 5 months’ gestation.
- Alveoli make milk in response to hormone prolactin. Suckling stimulates secretion of prolactin, which triggers milk production.
- Stimulation of areola causes secretion of oxytocin. Oxytocin is responsible for let-down reflex when myoepithelial cells contract and milk is ejected into milk ducts (3).
- Endocrine/metabolic: Cystic fibrosis, diabetes, galactosemia, phenylketonuria, and thyroid dysfunction may cause delayed lactation or decreased milk.

GENERAL PREVENTION

- Most vaccinations can be given to breastfeeding mothers. The CDC recommends that the diphtheria-tetanus-acellular pertussis, hepatitis B, inactivated influenza virus (as opposed to live attenuated), measles-mumps-rubella (MMR), and inactivated polio and varicella vaccines can be given. The CDC recommends avoiding the yellow fever or smallpox vaccine in breastfeeding mothers (4).
- The inactivated influenza virus is preferred to the live attenuated virus in women with infants age 6 to 23 months, regardless of whether these infants are being breastfed (4).
- Protective measures include breastfed infants who are more easily aroused than formula-fed infants, triggering a mechanism for the protective effect of breastfeeding against SIDS (5).

DIAGNOSIS

PHYSICAL EXAM

Examine breasts, ideally during pregnancy, looking for scars, lumps, or flat/inverted nipples. Confirm history of infertility, endocrine disorders, breast and hormonal pathology, overall health and psychosocial concerns, perinatal complications, and previous breastfeeding problem.

ALERT

A breast lump should be followed to complete resolution or worked up if present and not just attributed to changes from lactation.

TREATMENT

GENERAL MEASURES
Breastfeeding initiation
- Initiate breastfeeding immediately after birth, ideally placing the infant on mother’s chest uninterrupted skin-to-skin in first hour (1)[A],(5)[A].
- Mother placed in a comfortable position, usually sitting or leaning back, with baby naked on mom’s naked chest allowing baby to move toward breast.
- As baby opens wide, bring baby close, tucking baby in “belly to belly.” Line baby’s nose to nipple, baby tilts its head back with wide open mouth, bring baby close as baby latches to ensure baby’s gum takes in more of the areola.
- Baby’s lips are flanged, rounded cheeks, no clicking or popping sounds, and absence of nipple pain when latched.
- Feed baby on demand, practice rooming in, watch for hunger cues and cluster feeding.
- Feed baby 2 to 8 times for first 24 hours and 8 or more times per 24 hours, feeding 10 or more minutes, emptying and alternating breasts.
- Observation of a nursing session by an experienced physician, nurse, or IBCLC
- Avoid supplementation with formula or water and/or artificial nipples unless medically indicated.
- Contraindications to breastfeeding are few (WHO) (1).
  - Maternal HIV (in industrialized world) or human T-cell leukemia virus (HTLV) infection
  - Active untreated tuberculosis
  - Active herpes simplex virus (HSV) lesions on the breast*
  - Substances of abuse without evaluation
  - Review medications that will pass into human milk.
  - Infants with galactosemia or maple syrup urine disease should not be fed with breast milk. Infants with phenylketonuria may be fed breast milk under close observation.
  - Mothers who develop varicella 5 days before through 2 days after delivery*
  - Mothers acutely infected with influenza H1N1 until afebrile*
  - Maternal hepatitis is not a contraindication.
  - *Expressed milk can be used.

ISSUES FOR REFERRAL
- Refer to trained physician, nurse, or IBCLC for inpatient and/or outpatient teaching.
- Frequent follow-up if having problems with latching, sore nipples, breast pain, overactive let down, oversupply, inadequate milk production.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Galactagogues
- Metoclopramide, domperidone, oxytocin, fenugreek, goat’s rue, and milk thistle have mixed results in improving milk production, but efficacy and safety data are lacking in literature.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
See mother and baby within a few days of hospital discharge, especially if first time breastfeeding.
- Risk factors for suboptimal initiation
  - Breast surgery, especially reduction surgery, prior to pregnancy may disrupt breast milk
– Severe postpartum hemorrhage may lead to Sheehan syndrome, associated with difficulty breastfeeding due to poor milk production.
– Other factors: delivery mode, duration of labor, gestational age, maternal infection, parity, culture, mother–baby separation, maternal anxiety, use of artificial nipple, and non–breast milk fluids

Patient Monitoring

– Monitor maternal breast milk supply concerns.
– Supplementation with infant formula should be considered if infant has lost ≥10% of birth weight and is recommended if signs of dehydration such as decreased urine output are present.
– Supplementation without persistent breast stimulation with frequent feedings or breast pump use will decrease milk production and decrease breastfeeding success.

DIET

– Drink plenty of fluids to satisfy thirst and optimal hydration.
– Breastfeeding mothers may require ~500 more calories per day.
– Gassy foods can cause baby to be fussy.
– Limit caffeine to <300 mg/day.
– Alcohol should be avoided. Possible long-term effects of alcohol in maternal milk remain unknown. According the CDC, one drink/day has not been found to adversely effect the infant. In the U.S., one drink contains ~14 g of pure alcohol, which is found in: 12 oz of beer (~5% alcohol), 5 oz of wine (~12% alcohol), or 1.5 oz of distilled spirits (~40% alcohol). Intake over this level may impair the milk ejection reflex.
– Continue prenatal vitamin supplements.
– In 2008, the AAP increased its recommended daily intake of vitamin D for infants from 200 to 400 IU. For exclusively breastfed babies, this will require taking a vitamin supplement, such as Poly-Vi-Sol or Vi-Daylin vitamin drops, 0.5 mL/day, beginning in the first few days of life (1).
– In 2010, the AAP recommended adding supplementation for breastfed infants with oral iron 1 mg/kg/day beginning at age 4 months.
  o Preterm infants fed by human milk should receive an iron supplement of 2 mg/kg/day by 1 month of age, and this should be continued until the infant is weaned to iron-fortified formula or begins eating complementary foods that supply the 2 mg/kg of iron.
  o Fluoride supplement is unnecessary until 6 months of age (1).

PATIENT EDUCATION

– Primary care–initiated interventions and support measures to normalize breastfeeding have been shown to be successful with respect to child and maternal health outcomes.
– U.S. Preventive Services Task Force (USPSTF) recommends structured breastfeeding education and behavioral counseling programs to promote breastfeeding.
  o Regular promotion of the advantages of breastfeeding/risks of not breastfeeding (5)[A]
  o Emphasize importance of exclusive breastfeeding for first 4 weeks of life to allow
adequate buildup of sufficient milk supply.

- Milk usually transitions to mature milk about postpartum day 3 to 5.
- Frequent nursing (8 to 12 feedings per 24 hours by day 2)
- Baby should have 6 to 8 wet diapers per day and 3 to 4 bowel movements per day by day 6 to 8.
- Signs of adequate nursing
  - Baby feeding on demand
  - Proper latching and positioning, nipples intact
  - Hard breasts become soft after feeding.
  - Baby satisfied; appropriate weight gain (average 1 oz/day in first few months)
- Weaning
  - Solid food may be introduced at 4 months with continuation of breastfeeding.
  - Mothers returning to work/school should be introduced to alternative feeding methods 1 to 2 weeks prior. Initiate pumping to supply expressed breast milk.
- Family planning
  - Lactational amenorrhea method (LAM): Breastfeeding may be used as effective birth control option if (i) infant is <6 months old, (ii) infant is exclusively breastfeeding, and (iii) mother is amenorrheic.
  - Other options include barrier methods, implants, Depo-Provera, PO contraception, and intrauterine devices (IUDs). ACOG recommends that progesterone-only pills be used 2 to 3 weeks postpartum, and that Depo-Provera, IUDs, combined oral contraceptive pills, and Implanon can be used 6 weeks postpartum. However, ACOG recommends delaying use of combined OCPs until after 6 weeks postpartum when lactation is well established.
  - Monitor for changes in milk supply after starting a contraceptive.

COMPLICATIONS

- Breast milk jaundice should be considered if jaundice persists for >1 week in an otherwise healthy, well-hydrated newborn. It peaks at 10 to 14 days.
- Plugged duct
  - Mother is well except for sore lump in one or both breasts and is without fever.
  - Use moist, hot packs on lump prior to, and during, nursing; more frequent nursing on affected side
- Mastitis (see “Mastitis”)
  - Sore lump in one or both breasts plus maternal fever and/or redness on skin overlying lump
  - Use moist, hot packs on lump prior to, and during, nursing.
  - Antibiotics covering for Staphylococcus aureus (most common organism)
  - Other possible sources of fever should be ruled out, that is, endometritis and pyelonephritis.
  - Mother should get increased rest; use acetaminophen (Tylenol) PRN.
  - Fever should resolve within 48 hours or consider changing antibiotics. Lump should resolve. If it continues, an abscess may be present, requiring surgical drainage.
- Milk supply inadequate
  - Check infant weight gain.
  - Review signs of adequate supply; technique, frequency, and duration of nursing
  - Check to see if mother has been supplementing with formula, thereby decreasing her own milk production.
  - Review health concerns for causes of low milk supply.
- Sore nipples
– Check technique and improve latch-on.
– Baby should be taken off the breast by breaking the suction with a finger in the mouth.
– Air-dry nipples after each nursing and/or coat with expressed breast milk.
– Use lanolin cream to help in healing.
– Do not wash nipples with soap and water.
– Check for signs of thrush in baby and on mother’s nipple. If affected, treat both.
– Check for evidence of ankyloglossia (tongue tie) in the infant. Correction of ankyloglossia may lead to decreased nipple soreness and improved breastfeeding.
– Nipple Bleb (a blister on the nipple that can be filled with serous fluid or another fluid) due to improper positioning. Moist heat and improve latching techniques.

● Flat or inverted nipples
  – When stimulated, inverted nipples will retract inward, flat nipples remain flat; check for this on initial prenatal physical.
  – Nipple shells, a doughnut-shaped insert, can be worn inside the bra during the last month of pregnancy to force the nipple gently through the center opening of the shell.

● Engorgement
  – Develops after milk first comes in (day 3 or 4 postpartum), resolves within a day or 2
  – Signs are warm, hard, sore breasts.
    o To resolve, offer baby more frequent nursing; breastfeed long enough to empty breasts.
    o Pump to relieve discomfort.
    o Explore reasons for ongoing problems.

**CODES**

**ICD10**

Z39.1 Encounter for care and examination of lactating mother

**CLINICAL PEARLS**

• Women who do not receive support are at risk for shorter durations of breastfeeding.
• Virtually all mothers can breastfeed, provided they have accurate information, and the support of their family, the health care system, and society at large.
• Breast milk is the optimal food for infants, with myriad health benefits for mothers and children.
• USPSTF recommends regular, structured education during pregnancy to promote breastfeeding.
BRONCHIECTASIS
Sumera R. Ahmad, MD • Scott E. Kopec, MD

BASICS

DESCRIPTION
• Bronchiectasis is an irreversible dilatation of ≥1 airways accompanied by recurrent transmural bronchial infection/inflammation and chronic mucopurulent sputum production.
• Generally classified into cystic fibrosis (CF) and noncystic fibrosis (non-CF) bronchiectasis

EPIDEMIOLOGY
• Predominant age: most commonly presents in 6th decade of life
• Predominant sex: female > male

Incidence
Incidence has decreased in the United States for two reasons:
• Widespread childhood vaccination against pertussis
• Effective treatment of childhood respiratory infections with antibiotics

Prevalence
• In the United States, prevalence estimated to be 52.3/100,000
• Prevalence increased substantially with age from 4.2/100,000 persons aged 18 to 34 years to 271.8/100,000 among those aged ≥75 years.

ETIOLOGY AND PATHOPHYSIOLOGY
• CF bronchiectasis: bronchiectasis due to CF
• Non-CF bronchiectasis
  – Most cases are idiopathic.
  – Most commonly associated with non-CF bronchiectasis, a childhood infection.
• Vicious circle hypothesis: Transmural infection, generally by bacterial organisms, causes inflammation and obstruction of airways. Damaged airways and dysfunctional cilia foster bacterial colonization, which leads to further inflammation and obstruction.

RISK FACTORS
• Nontuberculous mycobacterial infection is both a cause and a complication of non-CF bronchiectasis.
• Severe respiratory infection in childhood (measles, adenovirus, influenza, pertussis, or bronchiolitis)
• Systemic diseases (e.g., rheumatoid arthritis and inflammatory bowel disease)
• Chronic rhinosinusitis
• Recurrent pneumonia
• Aspirated foreign body
• Immunodeficiency
• Congenital abnormalities

GENERAL PREVENTION
• Routine immunizations against pertussis, measles, Haemophilus influenzae type B, influenza,
and pneumococcal pneumonia
- Genetic counseling if congenital condition is etiology
- Smoking cessation

COMMONLY ASSOCIATED CONDITIONS
- Mucociliary clearance defects
  - Primary ciliary dyskinesia
  - Young syndrome (secondary ciliary dyskinesia)
  - Kartagener syndrome
- Other congenital conditions
  - $\alpha_1$-Antitrypsin deficiency
  - Marfan syndrome
  - Cartilage deficiency (Williams-Campbell syndrome)
- Chronic obstructive pulmonary disease
- Pulmonary fibrosis, causing traction bronchiectasis
- Postinfectious conditions
  - Bacteria (H. influenzae and Pseudomonas aeruginosa)
  - Mycobacterial infections (tuberculosis [TB] and Mycobacterium avium complex [MAC])
  - Whooping cough
  - Aspergillus species
  - Viral (HIV, adenovirus, measles, influenza virus)
- Immunodeficient conditions
  - Primary: hypogammaglobulinemia
  - Secondary: allergic bronchopulmonary aspergillosis (ABPA), posttransplantation
  - Sequelae of toxic inhalation or aspiration (e.g., chlorine, luminal foreign body)
- Rheumatic/chronic inflammatory conditions
  - Rheumatoid arthritis
  - Sjögren syndrome
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
- Miscellaneous
  - Yellow nail syndrome

DIAGNOSIS
- Typical symptoms include chronic productive cough, wheezing, and dyspnea.
- Symptoms are often accompanied by repeated respiratory infections.
- Once diagnosed, investigate etiology.

HISTORY
- Any predisposing factors (congenital, infectious, and/or exposure related)
- Immunization history

PHYSICAL EXAM
Symptoms are commonly present for many years and include the following:
- Chronic cough (90%)
- Sputum: may be copious and purulent (90%)
● Rhinosinusitis (60–70%)
● Fatigue: may be a dominant symptom (70%)
● Dyspnea (75%)
● Chest pain: may be pleuritic (20–30%)
● Hemoptysis (20–30%)
● Wheezing (20%)
● Bibasilar crackles (60%)
● Rhonchi (44%)
● Digital clubbing (3%)

DIFFERENTIAL DIAGNOSIS
● CF
● Chronic obstructive pulmonary disease
● Asthma
● Chronic bronchitis
● Pulmonary TB
● ABPA

DIAGNOSTIC TESTS & INTERPRETATION
● Spirometry
  – Moderate airflow obstruction and hyperresponsive airways
  – Forced expiratory volume in the 1st second of expiration (FEV$_1$): <80% predicted and
    FEV$_1$/FVC <0.7
  – Special tests
  – Ciliary biopsy by electron microscopy
● Sputum culture
  – H. influenzae, nontypeable form (42%)
  – P. aeruginosa (18%)
  – Cultures may also be positive for Streptococcus pneumoniae, Moraxella catarrhalis, MAC,
    and Aspergillus.
  – Screen for TB and non-TB in selected individuals.
  – Of all isolates, 30–40% will show no growth.
● Special tests
  – Sweat test for CF
  – Purified protein derivative (PPD) test for TB
  – Skin test for Aspergillus
  – HIV
  – Serum immunoglobulins to test for humoral immunodeficiency
  – Protein electrophoresis to test for α$_1$-antitrypsin deficiency
  – Barium swallow to look for abnormalities of deglutition, achalasia, esophageal hypomotility
  – pH probe to characterize reflux
  – Screening tests for rheumatologic diseases
● Chest radiograph
  – Nonspecific; increased lung markings or may appear normal
● Chest computed tomography (CT)
  – Noncontrast high-resolution chest CT is the most important diagnostic tool.
  – Bronchi are dilated and do not taper, resulting in “tram track sign”; parallel opacities seen
– Varicose constrictions and balloon cysts may be seen.
– For focal bronchiectasis, rule out endobronchial obstruction.
– For exclusively upper lobe bronchiectasis, consider CF and ABPA.

Diagnostic Procedures/Other
- Bronchoscopy may be used to obtain cultures and evacuate sputum.
- Bronchoscopy for hemoptysis
- Bronchoscopy may be useful to rule out airway-obstructing lesions with focal bronchiectasis.

Test Interpretation
Bronchoscopy findings include the following:
- Dilatation of airways and purulent secretions
- Thickened bronchial walls with necrosis of bronchial mucosa
- Peribronchial scarring

TREATMENT
- Treat underlying conditions.
- Recognize an acute exacerbation with four out of nine criteria.
  - Change in sputum production
  - Increased dyspnea
  - Increased cough
  - Fever
  - Increased wheezing
  - Malaise, fatigue, lethargy
  - Reduced pulmonary function
  - Radiographic changes
  - Changes in chest sounds
- Non-CF bronchiectasis: Determine cause of exacerbations; promote good bronchopulmonary hygiene via daily airway clearance.
- Consider surgical resection of damaged lung for focal disease that is refractory to medical management.
- Medical management: Reduce morbidity by controlling symptoms and preventing disease progression.
- Patients with non-CF bronchiectasis may not respond to CF treatment regimens in the same way as patients with CF do.

MEDICATION
- Insufficient evidence exists to support efficacy of short-course antibiotics in adults and children with bronchiectasis (2).
- Frequent exacerbations may be treated with prolonged and aerosolized antibiotics (3,4).
- Role of mucolytics, anti-inflammatory agents, and bronchodilators is still unclear.

First Line
- Antibiotics
  - Potentially useful in acute exacerbations
- Limited evidence supports quinolones over β-lactams for hospitalized patients.
- Chronic therapy decreases sputum production, number of exacerbations, and hospitalizations, but there is a risk of emergence of resistance to antibiotics (5,6).
- Use of inhaled antibiotics can be considered for selected individuals with gram-negative organisms. Caution needs to be taken with airway and systemic adverse effects noted with inhaled tobramycin and aztreonam (4).
- Patients may require twice the usual dose and longer treatment for 14 days (10 to 21 days) for an acute exacerbation.
- Sputum culture and sensitivity should direct therapy; antibiotic selection is complicated by a wide range of pathogens and resistant organisms.
- Should be administered by IV in cases of severe infection (4)
  - Ciprofloxacin: 750 mg PO q12h for adults
  - Amoxicillin clavulanate (Augmentin): 500 mg PO q8–12h; pediatric: base dosing on amoxicillin content
  - Trimethoprim/sulfamethoxazole (SMX): 160 mg trimethoprim/800 mg SMX PO q12h; pediatric: ≥2 months, 8 mg/kg trimethoprim and 40 mg/kg SMX PO/24 hours, administered in 2 divided doses q12h
  - Doxycycline and cefaclor given PO are also effective.
  - Nebulized aminoglycosides (tobramycin): 300 mg by aerosol BID
  - Macrolides: appear to have immunomodulatory benefits
- Chronic use of azithromycin as an oral macrolide for 6 to 12 months in non-CF bronchiectasis has been shown to reduce exacerbations; needs caution with respect to cardiovascular deaths, where it is a QTc-prolonging medication
- All patients considered for chronic therapy with azithromycin should be screened for non-TB mycobacterium infection prior (4).
- Bronchodilators
  - Chronic use of β2-agonists (e.g., albuterol) reverses airflow obstruction (2).
- Inhaled corticosteroids
  - Inhaled corticosteroids may improve lung function, but the effect is small (6).
    - Fluticasone propionate: 110 to 220 μg inhaled BID
  - Use of combination of long-acting bronchodilator with inhaled corticosteroid may reduce dyspnea, wheeze, and cough (6).
    - Budesonide 160 μg/formoterol 4.5 μg 2 puffs inhaled BID

**Second Line**
Other broad-spectrum antimicrobials, including those with antipseudomonal coverage

**ADDITIONAL THERAPIES**
Sputum clearance techniques, including chest physiotherapy (percussion and postural drainage) and pulmonary rehabilitation (improves exercise tolerance)

**SURGERY/OTHER PROCEDURES**
- Surgery if area of bronchiectasis is localized and symptoms remain intolerable despite medical therapy or if disease is life-threatening (3)
- Surgery effectively improves symptoms in 80% of these cases.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Bronchiectasis can present as life-threatening massive hemoptysis. In this situation, in addition to
airway protection and resuscitation, bronchial artery embolization or surgical intervention is necessary to control bleeding (2).

**ONGOING CARE**

Long-term outpatient treatment recommendations for bronchiectasis in children and adults (3):
- Children and adults with CF and non–CF-related bronchiectasis should be treated by comprehensive interdisciplinary chronic disease management programs.
- In children, aim to achieve normal growth and development.
- Patients with primary and secondary immune deficiencies should be under joint care with a clinical immunologist.
- Patient with CF should be referred to a CF center.
- Patient should be informed of the various techniques for airway clearance.
- Nebulized saline or hypertonic saline (7% saline) use prior to airway clearance techniques can help augment sputum production (3).[B].
- Whereas nebulized dornase and high-dose anti-inflammatory agents such as ibuprofen have some benefit in CF-related bronchiectasis, there is no role of such agents in non–CF-related bronchiectasis. In fact, nebulized dornase in adults can be harmful with more frequent exacerbations and decline in lung function.
- Pulmonary rehabilitation should be offered to patients with symptoms of breathlessness affecting activities of daily living (3).[B].
- In situation of an acute exacerbation, use and modify antibiotics as per sputum microbiology.
- Consider suitability of long-term antibiotics for patients with recurrent exacerbations.
- Noninvasive ventilation can improve quality of life in patients with chronic respiratory failure and can reduce hospitalizations.
- Consider lung transplant evaluation in patients with declining respiratory status and FEV$_1$ <30%. However, because non-CF bronchiectasis has significantly lower mortality hazard compared to CF-related bronchiectasis, separate referral and listing criteria should be considered (7).

**FOLLOW-UP RECOMMENDATIONS**

Regular exercise is recommended.

**Patient Monitoring**
- Serial spirometry at least annually (3)
- Chest CTs to monitor progression of disease may be indicated with some conditions such as bronchiectasis with MAC infections.
- Routine microbiologic sputum analysis

**PATIENT EDUCATION**

http://www.lungusa.org/

**PROGNOSIS**
- Mortality rate (death due directly to bronchiectasis) is 10.6–29.7% (7).
- Pseudomonas infection, low body mass index, and advanced age are associated with poorer prognosis (5).
COMPLICATIONS
- Hemoptysis
- Recurrent pulmonary infections
- Pulmonary hypertension
- Cor pulmonale
- Lung abscess

REFERENCES

ADDITIONAL READING

CODES
ICD10
- J47.9 Bronchiectasis, uncomplicated
- J47.1 Bronchiectasis with (acute) exacerbation
- J47.0 Bronchiectasis with acute lower respiratory infection

CLINICAL PEARLS
- Symptoms of bronchiectasis include chronic productive cough, wheezing, and dyspnea often accompanied by repeated respiratory infections.
- A chest x-ray has poor sensitivity and specificity for the diagnosis; a noncontrast high-resolution chest CT is the most important diagnostic tool.
- Current practice guidelines recommend treating acute exacerbations with a 14-day course of
antibiotics. Frequent exacerbations may be treated with prolonged and aerosolized antibiotics.
BRONCHIOLITIS
Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- Inflammation and obstruction of small airways and reactive airways generally affecting infants and young children—upper respiratory infection (URI) prodrome followed by increased respiratory effort, crackles, and wheezing
- Usual course: insidious, acute, progressive
- Leading cause of hospitalizations in infants and children in most Western countries
- Predominant age: newborn—2 years (peak age <6 months). Neonates are not protected despite transfer of maternal antibody.
- Predominant sex: male > female

EPIDEMIOLOGY

Incidence
- There is a 21–25% prevalence of bronchiolitis (<12 months of age, 13% 12 to 24 months) in the United States and it accounts for ~$1.7B in health care cost in United States. Incidence is estimated at 3.2/1,000. Almost 100% of children experience respiratory syncytial virus (RSV) infection by two seasons.
- Usually seasonal (October to May in the Northern Hemisphere) and often occurs in epidemics—in subtropical regions, RSV is endemic year-round
- Responsible for 18.8% (90,000 annually) of all pediatric hospitalizations (excluding live births) in children <2 years
- Incidence increasing since 1980 (with concomitant increase in relative rate of hospitalization from 2002 to 2007); of those <12 months with condition, the hospitalization rate ~2–3%

ETIOLOGY AND PATHOPHYSIOLOGY
RSV accounts for 70–85% of all cases (children <12 months of age), but rhinovirus, parainfluenza virus, adenovirus, influenza virus, Mycoplasma pneumoniae, and Chlamydomphila pneumoniae have all been implicated:
- Infection results in necrosis and lysis of epithelial cells and subsequent release of inflammatory mediators.
- Edema and mucus secretion, which combined with accumulating necrotic debris and loss of cilia clearance, result in airflow obstruction.
- Ventilation–perfusion mismatching resulting in hypoxia
- Air trapping is caused by dynamic airways narrowing during expiration, which increases work of breathing.
- Bronchospasm appears to play little or no role.

RISK FACTORS
- Secondhand cigarette smoke
- Low birth weight, premature birth
- Immunodeficiency
- Formula feeding (little or no breastfeeding)
Contact with infected person (primary mode of spread)
Children in daycare environment
Congenital cardiopulmonary disease
<12 weeks of age

**GENERAL PREVENTION**
- Hand washing or use of alcohol-based hand rubs (preferred)—this simple exercise has been estimated to have the largest impact on prevention of transmission.
- Contact isolation of infected babies
- Persons with colds should keep contact with infants to a minimum.
- Breastfeeding of infants has been associated with reduced morbidity of disease.
- Palivizumab (Synagis), a monoclonal product, administered monthly, October to May, 15 mg/kg IM; used for RSV prevention ONLY in high-risk patients (see American Academy of Pediatrics [AAP] recommendations) (1)

**Pediatric Considerations**
Prior infection does not seem to confer subsequent immunity.

**COMMONLY ASSOCIATED CONDITIONS**
- Upper respiratory congestion
- Conjunctivitis
- Pharyngitis
- Otitis media
- Diarrhea

**DIAGNOSIS**
History and physical examination should be the basis for the diagnosis of bronchiolitis; ancillary testing only indicated if clinical picture is unclear (no single of group of tests confirmatory for bronchiolitis)

**HISTORY**
- Irritability
- Anorexia
- Fever
- Noisy breathing (due to rhinorrhea)
- Cough
- Grunting
- Cyanosis
- Apnea
- Vomiting

**PHYSICAL EXAM**
- Tachypnea
- Retractions (increased work of breathing)
- Rhinorrhea
- Wheezing
- Upper respiratory findings: pharyngitis, conjunctivitis, otitis
DIFFERENTIAL DIAGNOSIS
- Other pulmonary infections such as pertussis, croup, or bacterial pneumonia
- Aspiration
- Vascular ring
- Foreign body
- Asthma
- Heart failure
- Gastroesophageal reflux
- Cystic fibrosis

DIAGNOSTIC TESTS & INTERPRETATION
Laboratory and other ancillary testing (including chest x-ray) are not required if clinical diagnosis is bronchiolitis. Recent meta-analysis found no single history or physical factor that predicted air-space disease on chest radiograph.

Initial Tests (lab, imaging)
- Arterial oxygen saturation by pulse oximetry. Results need to be interpreted in clinical context. Transient hypoxemia is a common phenomenon in healthy infants (1); capnography not found to aid in prediction of disease severity or need for hospitalization
- Rapid respiratory viral antigen testing is not necessary during RSV season because the disease is managed symptomatically but may be useful for epidemiologic, hospital cohorting, or in the very young to reduce unnecessary other workup; also indicated in infants admitted while receiving palivizumab prophylaxis (if positive, prophylaxis may be discontinued)
- The AAP does not recommend routine RSV testing in infants and children with bronchiolitis.
- Chest x-ray findings are variable and may include atelectasis, peribronchial cuffing, hyperinflation, and perihilar infiltrates (AAP, others do not recommend routine chest radiographs in clinical picture of acute bronchiolitis) (1)

Diagnostic Procedures/Other
Point of care ultrasound (POCUS) is being utilized to assist with diagnosis of pneumonia in bronchiolitis with accuracy comparable to radiographs. Also use of a POCUS-derived scoring system may prognosticate patients who need escalation of therapy (2).

TREATMENT
The cornerstone of therapy is supportive to include upper airway suctioning, prevention of significant and prolonged hypoxia, and dehydration. The other interventions noted have historically varying effect on the course of the illness despite numerous studies. Recent clinical practice guidelines do not support the routine use of corticosteroids, bronchodilators, or epinephrine. Despite the recommendations against such treatments, some estimated 50% of patients receive some combination of medication during their course (3). Parental education and support is vital (1)[A].

MEDICATION
First Line
- Humidified oxygen for hypoxia of <90% (many feel that transient pulse oximetry in 85–90% range during sleeping in clinically well-appearing infant may be observed) (1)[C]
Nebulized hypertonic saline (3%) can be effective in reducing length of stay in hospitalized patients but not recommended use in the emergency department (more recent literature review shows some signal of benefit) (1,4)[B].

Antibiotics only if secondary bacterial infection present (rare); not indicated for routine use (1) [B]

Positive-pressure ventilation (PPV) in the form of continuous positive airway pressure (CPAP) can be used in cases of respiratory failure. There is limited clinical evidence other than observational studies.

High-flow nasal cannula oxygen widely used in various settings to improve oxygen saturation with resultant reduction in end-tidal CO₂ (ETCO₂) and respiratory rate, but overall effectiveness remains unproven to date. Recent RCT indicates that high-flow oxygen therapy is effective in treating those potentially needing escalated therapy (5).

**ADDITIONAL THERAPIES**

- Ribavirin and palivizumab for patients at high risk (for prophylaxis per Centers for Disease Control and Prevention/AAP guidelines)
- Heliox therapy (70% helium and 30% oxygen) may be of benefit early in moderate to severe bronchiolitis to reduce degree of respiratory distress due to air flow restriction, but Cochrane Review found little evidence of sustained benefit at 24 hours.
- Although not routinely recommended, inhaled β-agonists (albuterol) can be effective in selected cases (particularly in patients with a history of bronchospasm). Many clinicians will attempt an empiric trial of bronchodilators in a primary presentation to judge the clinical response (some argue that this condition maybe asthma equivalent).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Bronchiolitis can be associated with apnea in children <6 weeks of age.
- Respiratory rate >45 breaths/min with respiratory distress or apnea
- Hypoxia is common, so clinical criteria are more helpful (pulse oximetry <94% used by many as cutoff).
- Ill or toxic appearance
- Underlying heart condition, respiratory condition, or immune suppression
- High risk for apnea (age <30 days, preterm birth [<37 weeks])
- Dehydrated or unable to feed (<50% of normal intake suggested as threshold for hospitalization consideration)
- Uncertain home care
- Use of respiratory distress assessment instrument may aid in determining admission. The five best predictors of admission, age, respiratory rate, heart rate, oxygen saturation, and duration of symptoms, were recently incorporated into a scoring instrument.
- Supplemental oxygen for pulse oximetry <94% on room air if clinically indicated (i.e., retractions, increased WOB, etc.). AAP recommends O₂ saturation >90% if infant otherwise well.
- IV fluids indicated only if tachypnea precludes oral feeding; weight-based maintenance rate plus insensible losses
- Discharge criteria
  - Normal respiratory rate and no oxygen requirement: Recent small studies suggest that after a period of observation, children can be safely discharged on home oxygen with home health follow-up. Despite reassuring appearance, the clinical course is unpredictable, so
follow-up and parental education is important.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hospitalization is usually required only if oxygen is a requirement or unable to feed/drink.
- For a hospitalized patient, monitor as needed depending on the severity of the infection.
- If the patient is receiving home care, follow daily by telephone call for 2 to 4 days; the patient may need frequent office visits.

PATIENT EDUCATION

- American Academy of Family Physicians: http://www.familydoctor.org

PROGNOSIS

- Recovery time is variable. 40% can have symptoms at 14 days and 10% at 4 weeks.
- Mortality statistics differ but probably <1%.
- High-risk infants (bronchopulmonary dysplasia, congenital heart disease) may have a prolonged course.

COMPLICATIONS

- Bacterial superinfection
- Bronchiolitis obliterans
- Apnea
- Respiratory failure
- Death
- Increased incidence of development of reactive airway disease (asthma)

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- J21.9 Acute bronchiolitis, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus
- J21.8 Acute bronchiolitis due to other specified organisms

**CLINICAL PEARLS**
- Bronchiolitis is the leading cause of hospitalizations in infants and children—especially <3 months of age.
- Diagnosis is a clinical one of children in the first 2 years of life, associated with rhinorrhea, cough, labored breathing, and irritability.
- RSV causes the majority of bronchiolitis. Chest x-ray is not indicated.
- Parental education and support is essential.
- Treatment: Nasal and upper airway suctioning mainstay of treatment
BRONCHITIS, ACUTE
Ghazaleh Bigdeli, MD, FCCP

BASICS

DESCRIPTION
- Inflammation of trachea, bronchi, and bronchioles resulting from a respiratory tract infection or chemical irritant (1)
- Cough, the predominant symptom, may last as long as 3 weeks (2,3).
- Generally self-limited, with complete healing and full return of function (2).
- Most infections are viral if no underlying cardiopulmonary disease is present (2).
- Synonym(s): tracheobronchitis

Geriatric Considerations
Can be serious, particularly if part of influenza, with underlying chronic obstructive pulmonary disease (COPD) or congestive heart failure (3)

Pediatric Considerations
- Usually occurs in association with other conditions of upper and lower respiratory tract (trachea usually involved)
- If repeated attacks occur, child should be evaluated for anomalies of the respiratory tract, immune deficiencies, or for asthma.
- Acute bronchitis caused by respiratory syncytial virus (RSV) may be fatal.
- Antitussive medication not indicated in patients age <6 years (2)

EPIDEMIOLOGY
- Predominant age: all ages
- Predominant gender: male = female

Incidence
- ~5% of adults per year
- Common cause of infection in children

Prevalence
Results in 10 to 12 million office visits per year

ETIOLOGY AND PATHOPHYSIOLOGY
- Viral infections such as adenovirus, influenza A and B, parainfluenza virus, coxsackievirus, RSV, rhinovirus, coronavirus (types 1 to 3), herpes simplex virus, metapneumovirus (2)
- Bacterial infections, such as Chlamydia pneumoniae, Mycoplasma, Bordetella pertussis, Haemophilus influenzae, Streptococcus pneumoniae, Moraxella catarrhalis, and Mycobacterium tuberculosis (2)
- Secondary bacterial infection as part of an acute upper respiratory infection
- Possible fungal infections
- Chemical irritants
- Acute bronchitis causes an injury to the epithelial surfaces, resulting in an increase in mucus production and thickening of the bronchiole wall (1).
Genetics
No known genetic pattern

RISK FACTORS
- Infants
- Elderly
- Air pollutants
- Smoking
- Secondhand smoke
- Environmental changes
- Chronic bronchopulmonary diseases
- Chronic sinusitis
- Tracheostomy or endobronchial intubation
- Bronchopulmonary allergy
- Hypertrophied tonsils and adenoids in children
- Immunosuppression
  - Immunoglobulin deficiency
  - HIV infection
  - Alcoholism
- Gastroesophageal reflux disease (GERD)

GENERAL PREVENTION
- Avoid smoking and secondhand smoke.
- Control underlying risk factors (i.e., asthma, sinusitis, and reflux).
- Avoid exposure, especially daycare.
- Pneumovax, influenza immunization

COMMONLY ASSOCIATED CONDITIONS
- Allergic rhinitis
- Sinusitis
- Pharyngitis
- Epiglottitis (rare but can be rapidly fatal)
- Coryza
- Croup
- Influenza
- Pneumonia
- Asthma
- COPD/emphysema
- GERD

DIAGNOSIS

HISTORY
- Cough for >5 days and no evidence of pneumonia, asthma, exacerbation of COPD (3)
- Cough is initially dry and nonproductive, then productive; later, mucopurulent sputum, which may indicate secondary infection
• Cough lasts >5 days (1).
• Dyspnea, wheeze, and fatigue may occur.
• Possible contact with others who have respiratory infections (1)
• Fever may suggest pneumonia or influenza infection (1).

PHYSICAL EXAM
• Fever
• Tachypnea
• Pharynx injected
• Rhonchi, wheezing
• No evidence of pulmonary consolidation, rales, etc.

DIFFERENTIAL DIAGNOSIS
• Common cold
• Acute sinusitis
• Bronchopneumonia
• Influenza
• Bacterial tracheitis
• Bronchiecstasy
• Asthma
• Reactive airways dysfunction syndrome (RADS)
• Allergy
• Eosinophilic pneumonitis
• Aspiration
• Retained foreign body
• Inhalation injury
• Cystic fibrosis
• Bronchogenic carcinoma
• Heart failure
• GERD
• Chronic cough

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• None normally needed; diagnosis is based on history and physical exam showing no postnasal drip or rales (1,3).
• For a complicated picture, consider the following:
  – CBC with differential
  – Influenza titers (if appropriate for time of year) (1)
  – Viral panel
• No testing needed unless concerned about pneumonia
• Pulse oximetry if underlying pulmonary disease is present
• CXR
  – Lungs normal, if uncomplicated
  – Helps to rule out other diseases (pneumonia) or complications

Follow-Up Tests & Special Considerations
• Arterial blood gases: hypoxemia (rarely)
- Pulmonary function tests (seldom needed during acute stages): increased residual volume, decreased maximal expiratory rate (2)
- Sputum culture in those patients intubated or with tracheostomy

**TREATMENT**

**GENERAL MEASURES**
- Outpatient treatment unless elderly or complicated by severe underlying disease
- Rest
- Stop smoking and avoid secondhand smoke.
- Steam inhalations
- Vaporizers
- Adequate hydration
- Antitussives
- Antibiotics are usually not recommended (1,3,4)[A].
- Treat associated illnesses (e.g., GERD).

**MEDICATION**

**ALERT**
Antibiotics are not recommended (1,3)[A] unless a treatable pathogen has been identified or significant comorbidities are present. This should be explained to patients who likely expect an antibiotic to be prescribed (3)[B].

**First Line**
- Supportive; increased fluids (Cough results in increased fluid loss.)
- Antipyretic analgesic such as aspirin, acetaminophen, or ibuprofen
- Decongestants if accompanied by sinus condition
- Cough suppressant for troublesome cough (not with COPD); honey (1 tbsp every 2–4 hours as needed), benzonatate (Tessalon), guaifenesin with dextromethorphan; not indicated in children age <6 years (2)[C]
- Mucolytic agents are not recommended (3)[B].
- Inhaled β-agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm in those with known airflow obstruction (2,5)[B]
- If influenza is highly suspected and symptom onset is <48 hours: oseltamivir (Tamiflu), zanamivir (Relenza) (2)[B] intravenous peramivir (trade name Rapivab) or baloxavir marboxil (Xofluza)
- Antibiotics ONLY if a treatable cause (i.e., pertussis) is identified (2)[A].
  - Clarithromycin (Biaxin): 500 mg q12h or azithromycin (Zithromax) Z-Pak for atypical or pertussis infection (1)[A]
  - In patients with acute bronchitis of a suspected bacterial cause, azithromycin tends to be more effective in terms of lower incidence of treatment failure and adverse events than amoxicillin or amoxicillin-clavulanic acid (6)[B].
    - Doxycycline: 100 mg/day × 10 days if Moraxella, Chlamydia, or Mycoplasma suspected
    - Quinolone for more serious infections or other antibiotic failure or in elderly or patients with multiple comorbidities
Contraindication(s): Doxycycline and quinolones should not be used during pregnancy or in children.

Precautions:
- Multiple antibiotics have the potential to interfere with the effectiveness of oral contraceptives.
- Antibiotic use can be associated with Clostridium difficile infections.
- Cough and cold preparations should not be used in children <6 years (2)[B].

**Second Line**
Other antibiotics if indicated by sputum culture

**ISSUES FOR REFERRAL**
- Complications such as pneumonia or respiratory failure
- Comorbidities such as COPD
- Cough lasting >3 months

**ADDITIONAL THERAPIES**
- Antipyretic for fever (e.g., acetaminophen, or ibuprofen)
- Inhaled β-agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm (2)[B]
- Oral corticosteroids probably not indicated (2)[C]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Throat lozenges for pharyngitis

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Hypoxia—may require supplemental oxygen
- Respiratory failure that may require continuous positive airway pressure/bilevel ventilation
- Severe bronchospasm
- Exacerbation of underlying disease
- Bronchodilators if patient is bronchospastic
- IV fluids may be helpful if patient is dehydrated.
- Ensure patient comfort and monitor for signs of deterioration, especially if underlying lung disease exists.
- May need to follow oxygen saturation in patients with underlying lung disease
- Discharge criteria: improvement in symptoms and comorbidities

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Usually a self-limited disease not requiring follow-up
- Cough may linger for several weeks.
- In children, if recurrent, need to consider other diagnoses, such as asthma (4)

**Patient Monitoring**
- Oximetry until no longer hypoxemic
- Recheck for chronicity.
DIET
Increased fluids (3 to 4 L/day) while febrile

PATIENT EDUCATION
- For patient education materials favorably reviewed on this topic, contact the American Lung Association: 1740 Broadway, New York, NY 10019 (212) 315-8700; www.lungusa.org
- American Academy of Family Physicians: www.familydoctor.org

PROGNOSIS
- Usual: complete resolution
- Can be serious in the elderly or debilitated
- Cough may persist for several weeks after an initial improvement.
- Postbronchitic reactive airways disease (rare)
- Bronchiolitis obliterans and organizing pneumonia (rare)

COMPLICATIONS
- Superinfection such as bronchopneumonia
- Bronchiectasis
- Hemoptysis
- Acute respiratory failure
- Chronic cough

REFERENCES

ADDITIONAL READING

SEE ALSO
- Algorithm: Cough, Chronic
Asthma; Chronic Obstructive Pulmonary Disease and Emphysema

CODES

ICD10
- J20.9 Acute bronchitis, unspecified
- J68.0 Bronchitis and pneumonitis due to chemicals, gases, fumes and vapors
- B97.0 Adenovirus as the cause of diseases classified elsewhere

CLINICAL PEARLS
- Acute bronchitis is a common and generally self-limited disease.
- Treat cough with honey (1 tbsp every 2–4 hours as needed), benzonatate (Tessalon), guaifenesin with dextromethorphan
- It does not require treatment with antibiotics. This needs to be explained to patients who expect antibiotics to be prescribed.
- Cough may linger for several weeks after the resolution of other symptoms.
- Recurrent or seasonal episodes may suggest another disease process, such as asthma.
- Fever is uncommon and should prompt investigation for pneumonia or influenza.
BULIMIA NERVOSA
Umer Farooq, MD  Ayesha Fatima, MBBS

BASICS

DESCRIPTION
Bulimia nervosa is an eating disorder that includes binge eating and inappropriate compensatory behaviors.

- Binge eating is characterized by eating, in a discrete period of time (within 2-hour period), an amount of food that is larger than most people would eat during a similar period of time, and a sense of lack of control over eating during the episode, followed by recurrent inappropriate compensatory behavior to prevent weight gain, such as self-induced vomiting, misuse of laxatives, excessive exercise, and so forth.
- Binge eating and inappropriate compensatory behaviors both occur once a week for 3 months.
- Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) classifies bulimia nervosa severity as the following:
  - Mild: 1 to 3 episodes of inappropriate compensatory behaviors per week
  - Moderate: 4 to 7 episodes of inappropriate compensatory behaviors per week
  - Severe: 8 to 13 episodes of inappropriate compensatory behaviors per week
  - Extreme: 14 or more episodes of inappropriate compensatory behaviors per week
- System(s) affected: oropharyngeal, endocrine/metabolic, gastrointestinal, dermatologic, cardiovascular, pulmonary, psychiatric

EPIDEMIOLOGY
- Predominant age: adolescents and young adults
- Mean age of onset: 18 to 21 years
- Predominant sex: female > male (13:1)

Incidence
28.8 women, 0.8 men per 100,000 per year

Prevalence
- More prevalent than anorexia nervosa
- 1.5% in women age 16 to 35 years
- 0.5% in young men

ETIOLOGY AND PATHOPHYSIOLOGY
- Combination of biologic, psychological, environmental, and social factors. Unique contribution of any specific factor remains unclear.
- Strong evidence of serotonergic dysregulation in bulimia nervosa
- Substantial literature shows genetic evidence for bulimia nervosa.
- Multiple studies demonstrate altered brain function and structure in bulimia nervosa.

RISK FACTORS
- Female gender
- History of obesity and dieting
Body dissatisfaction: critical comments about weight, body shape, or eating: low self-esteem
Severe life stressor
Perfectionist or obsessive thinking
Poor impulse control, substance abuse
Environment stressing high achievement, physical fitness (e.g., armed forces, ballet, cheerleading, gymnastics, or modeling): perceived pressure to be thin
Family history of substance abuse, affective disorders, eating disorder, or obesity
Type 1 diabetes
Childhood trauma (sexual abuse)

GENERAL PREVENTION
Prevention programs can reduce risk factors and future onset of eating disorders.
Target adolescents and young women ≥15 years.
Realistic and healthy weight management strategies and attitudes
Decrease body dissatisfaction and promote self-esteem.
Reduce focus on thin as ideal.
Decrease anxiety/depressive symptoms and improve stress management.

COMMONLY ASSOCIATED CONDITIONS
Major depression and dysthymia
Anxiety disorders
Substance use disorder
Bipolar disorder
Obsessive-compulsive disorder
Borderline personality disorder

DIAGNOSIS
HISTORY
Patients unlikely to self-identify binge eating or purging behaviors; corroborate with parent/relative.
Unhappiness and/or preoccupation with weight and diet attempts
Pattern of binge eating and compensatory behaviors
– Binge is context specific (usually within 2-hour period, they will eat what would be an unusually large amount for most people).
– Vomiting (often with little effort)
– Vigorous aerobic exercise
– Distress/shame related to loss of control
Depressed mood and self-deprecation following the binges
Other possible signs and symptoms
– Requesting weight loss help and mildly underweight to overweight
– Diet pill, diuretic, laxative, ipecac, and thyroid medication use/abuse, frequent fluctuations in weight
– Menstrual disturbance
– Fatigue and lethargy
– Abdominal pain, bloating, constipation, diarrhea, rectal prolapse
– Sore throat and thermal tooth sensitivity
– Omission/underdosing insulin in diabetes patients

Screening
– Clinician administered eating-disorder screen for primary care to identify patients with eating disorders.
  o Are you satisfied with your eating patterns? (No is abnormal.)
  o Do you ever eat in secret? (Yes is abnormal.)
  o Does your weight affect the way you feel about yourself? (Yes is abnormal.)
  o Have any members of your family suffered with an eating disorder? (Yes is abnormal.)
  o Do you currently suffer with or have you ever suffered in the past with an eating disorder? (Yes is abnormal.)

PHYSICAL EXAM
– Often normal
– Tachycardia
– Erosion of dental enamel
– Perimyolysis, cheilosis, gingivitis
– Sialadenosis (parotid gland swelling and/or asymptomatic, noninflammatory parotid gland enlargement)
– Epigastric tenderness to palpation
– Calluses, abrasions, bruising on hand, thumb (Russell sign)
– Peripheral edema

DIFFERENTIAL DIAGNOSIS
– Anorexia, binge eating/purging type
– Major depressive disorder
– Addison disease
– Celiac disease
– Diabetes mellitus
– Hyperthyroidism, hypothyroidism
– Hyperpituitarism
– Hypothalamic brain tumor
– Kleine-Levin syndrome
– Body dysmorphic disorder
– Borderline personality disorder

DIAGNOSTIC TESTS & INTERPRETATION
All lab results may be within normal limits and are not necessary for diagnosis.
– Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the DSM-5 criteria:
  – SCOFF Questionnaire (1)[B]
  – Primary Care Evaluation of Mental Disorders Patient Health Questionnaire

Initial Tests (lab, imaging)
– Blood work, complete blood count, comprehensive metabolic panel, and liver function tests
  – Hypokalemia, hypochloremia
  – Hypomagnesemia, hyponatremia, hypocalcemia, hypophosphatemia, hypoglycemia
  – Serum amylase levels and alkalosis
– Elevated blood urea nitrogen
● Urinalysis
  – Increased urine specific gravity

**Diagnostic Procedures/Other**
● Pregnancy test
● Electrocardiogram: bradycardia or arrhythmias, conduction defects, depressed ST segment due to hypokalemia

**Test Interpretation**
● Esophagitis
● Acute pancreatitis
● Cardiomyopathy and muscle weakness due to ipecac abuse
● Melanosis coli and cathartic colon syndrome
● Delayed or arrested skeletal growth
● Stress fracture and/or osteopenia/osteoporosis
● Irreversible dental erosions

---

**TREATMENT**

Cognitive-behavioral therapy (CBT) should be considered as first-line treatment (2,3)[A].

**GENERAL MEASURES**
● Multidisciplinary team
  – Primary care physician, behavioral health provider, nutritionist
● Build trust; increase motivation for change.
● Assess psychological and nutritional status.
● Consider evidence-based self-help program.

<table>
<thead>
<tr>
<th>CBT for bulimia nervosa (2,3)[A]</th>
</tr>
</thead>
<tbody>
<tr>
<td>– 16–20 50-minute appointments</td>
</tr>
<tr>
<td>– Involve patient in establishing goals.</td>
</tr>
<tr>
<td>– Self-monitoring of food intake, frequency of binges/purges, related antecedents, consequences, thoughts, and emotions</td>
</tr>
<tr>
<td>– Self-monitoring of weight once per week</td>
</tr>
<tr>
<td>– Educate about ineffectiveness of purging for weight control and adverse outcomes.</td>
</tr>
<tr>
<td>– Establish prescribed eating plan to develop regular eating habits and realistic weight goal.</td>
</tr>
<tr>
<td>– Gradually introduce feared foods into diet and challenge fear of loss of control.</td>
</tr>
<tr>
<td>– Problem-solve how to cope with triggers.</td>
</tr>
<tr>
<td>– Decrease ruminations about calories, weight, and purging.</td>
</tr>
<tr>
<td>– Establish relapse prevention plan.</td>
</tr>
<tr>
<td>– Gradual laxative withdrawal</td>
</tr>
</tbody>
</table>

● Interpersonal therapy
  – May act more slowly than CBT
● Transdiagnostic CBT
● Dialectical behavior therapy
● Family therapy for adolescents
● Nutritional education, relaxation techniques
- Educate patient to brush teeth and use baking soda to rinse mouth after vomiting.

**ALERT**
Contraindications to treating bulimia nervosa with CBT (4)[B] are

- Medical instability
- Severe major depression
- Substance use disorder
- Suicidal ideation or behavior
- Psychosis

**MEDICATION**

**First Line**
- Selective serotonin reuptake inhibitors (SSRIs) (5)[A], particularly fluoxetine (Prozac) titrated to 60 mg/day, are effective in reducing symptoms with relatively few side effects. Higher doses than standard doses for depression are often needed.
  - Combination of medication and CBT has been shown to have added benefit over medication or therapy alone.
- To prevent relapse, maintain antidepressant at full therapeutic dose for at least 1 year.
- Avoid bupropion: contraindicated due to its association with seizures in patients who purge
- Precautions
  - Serious toxicity following overdose is common.
  - Patients may vomit medications.

**Second Line**
- Select different SSRI (citalopram, fluvoxamine, and sertraline).
- Ondansetron (Zofran) 4 to 8 mg TID between meals can help prevent vomiting.
- The anticonvulsant topiramate may have some usefulness in helping to diminish binge-purge episodes in bulimic patients. Additionally, bright light therapy in certain controlled trials has reduced binge-purge frequency in bulimia nervosa patients.
- Psyllium (Metamucil) preparations, 1 tbsp QHS with glass of water, can prevent constipation during laxative withdrawal.

**ISSUES FOR REFERRAL**
Patients with bulimia require a multidisciplinary team, including a primary care physician, behavioral health provider, and a nutritionist. Important part of treatment is to arrange mental health therapist for psychotherapy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Bright light therapy may help.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Most patients can be treated as outpatients, however admission (to a specialized eating disorders unit if available) is indicated for the following conditions:
  - Syncope
  - Potassium <3.0
  - Esophageal tears
  - Cardiac arrhythmias
  - Hypothermia
Suicide risk
Intractable vomiting
Hematemesis
Severe malnutrition
Failure to response outpatient treatment

During admission:
Supervised meals and bathroom privileges
Monitor weight and physical activity.
Monitor electrolytes.
Gradually shift control to patients as they demonstrate improvement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Binge/purge activity, including antecedents and consequences, level of exercise activity
- Self-esteem, comfort with body and self
- Ruminations and depressive symptoms
- Repeat any abnormal lab values weekly or monthly until stable.

Diet
- Balanced diet, normal eating pattern
- Nutritional rehabilitation aims to restore a structured and consistent meal pattern: three meals and two snacks per day

PATIENT EDUCATION
https://www.nami.org/Learn-More/Mental-Health-Conditions/Eating-Disorders/Overview

PROGNOSIS
- After effective CBT
  - In the short term, 50% of treated individuals do not meet criteria for diagnosis.
  - In the long term (2 to 10 years), 70% may be asymptomatic.
  - Symptomatic individuals may demonstrate remissions, relapses, subclinical, or other eating disorder–related behaviors.
- Untreated
  - Likely to remain chronic/relapsing problem
- Greater weight fluctuations, other impulsive behaviors, childhood obesity, low self-esteem, family history of alcohol abuse, psychiatric comorbidity, and personality disorder diagnoses (e.g., avoidant personality disorder) may predict poor prognosis.
- Mortality rate: 0.4%. The death rate for bulimia nervosa is much lower than that for anorexia nervosa. Patients who remain in remission for >1 year have a better long-term outcome.

COMPLICATIONS
- Substance use disorder
- Osteopenia/osteoporosis
- Stress fracture
- Gastric dilatation
- Boerhaave syndrome
- Mallory-Weiss tears
- Pseudo-Barter syndrome
- Spontaneous pneumomediastinum
- Potassium depletion, cardiac arrhythmia, cardiac arrest
- Suicide

**Pregnancy Considerations**
Maternal and fetal problems if pregnant
- Binging/purging behaviors may persist, increase, or decrease with pregnancy.
- Increased risk for preterm delivery, operative delivery, and infants with low birth weight should be managed as high risk.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
F50.2 Bulimia nervosa

**CLINICAL PEARLS**

- Asking “Are you satisfied with your eating patterns?” and/or “Do you worry that you have lost control over how much you eat?” may help to screen for an eating problem.
- Consider multidisciplinary team approach with PCP, behavioral health provider, and nutritionist.
- SSRIs, particularly fluoxetine (60 mg daily), may be helpful as a first step or as an adjunctive treatment with CBT.
Pharmacotherapy alone is reasonable if specialized nutritional rehabilitation and psychotherapy are not available.
BUNION (HALLUX VALGUS)
Jennifer G. Chang, MD

BASICS

DESCRIPTION
- Lateral deviation of the great toe (“Hallux abducto valgus” derives from the Latin for “big toe askew.”)
- Associated medial deviation of the 1st metatarsal, leading to a medial prominence of the 1st metatarsophalangeal (MTP) joint (also known as “bunion”)
- Progressive subluxation of the 1st MTP joint in later stages
- System(s) affected: musculoskeletal/skin

EPIDEMIOLOGY
- Predominant age: more common in adults
  - Estimated 23% in adults aged 18 to 65 years
  - Estimated 35.7% in elderly >65 years
- Predominant sex: female > male by ~2:1

Prevalence
- Prevalence increases with age particularly in females.
- Juvenile hallux valgus
  - More common in girls (>80% of cases)
- Commonly bilateral

ETIOLOGY AND PATHOPHYSIOLOGY
Multifactorial. Contributing factors include the following:
- Valgus deviation of the hallux promotes varus position of the 1st metatarsal.
- Medial MTP joint capsule stretches and attenuates, whereas the lateral capsule contracts.
- Metatarsal head moves medially, shifting the sesamoid bones to a more lateral position.
- Extensor hallucis longus deviates laterally.
- Lateral and plantar migration of abductor hallucis moves the great toe into plantar flexion and lateral pronation.
- Medial collateral ligament stretches and eventually ruptures, decreasing stability and causing progressive subluxation of the 1st MTP joint.

RISK FACTORS
- Genetic predisposition
- Abnormal biomechanics (i.e., flexible flat feet)
- Foot deformities: joint laxity, hindfoot pronation, Achilles tendon tightness, pes planus (fallen arches), metatarsus primus varus
- Amputation of 2nd toe
- Inflammatory joint disease
- Neuromuscular disorders (cerebral palsy, stroke)
- Improper footwear (high heels; narrow toe box)
GENERAL PREVENTION
Proper footwear may decrease the progression of the disease.

COMMONLY ASSOCIATED CONDITIONS
- Medial bursitis of the 1st MTP joint (most common)
- Hammertoe deformity of the 2nd phalanx
- Plantar callus
- Metatarsalgia
- Degeneration of 1st metatarsal head cartilage
- Pronated feet; ankle equinus
- Onychocryptosis (ingrown toenail)
- Entrapment of the medial dorsal cutaneous nerve
- Synovitis of the MTP joint

DIAGNOSIS
- Based on clinical exam
- Radiographs are used for staging.

HISTORY
- Painful MTP joint (most common symptom in adults)
- Abnormal position of great toe
- Enlargement of the MTP joint medially (patients complain of a “bump”)
- Shoes do not fit properly.
- Pain with ambulation
- Skin irritation, blister, or callus at the 1st MTP

PHYSICAL EXAM
- Observe gait; may be antalgic due to pain
- Medial prominence at the MTP joint
- Skin changes: erythema, blistering, callus or ulceration at the MTP joint
- Great toe over- or underriding the 2nd toe
- Examine the entire 1st metatarsal and toe for:
  - 1st MTP range of motion
  - 1st tarsometatarsal (TMT) mobility
  - Neurovascular integrity
  - Degenerative osteoarthritis

DIFFERENTIAL DIAGNOSIS
- Trauma
  - Turf toe; sesamoiditis; stress fracture
- Infection
  - Osteomyelitis; septic arthritis
- Joint disorder
  - Osteoarthritis; rheumatoid arthritis; pseudogout; gout
- Tendon disorder
  - Tendinosis; tenosynovitis; tendon rupture
DIAGNOSTIC TESTS & INTERPRETATION

- Weight-bearing AP and lateral radiographs (sesamoid view optional) to assess:
  - Joint congruency and degenerative changes
  - Lateral sesamoid bone displacement
  - Rounded 1st metatarsal head
  - Longer 1st metatarsal

- Radiographic parameters:
  - Hallux valgus angle (HVA): Long axis of the 1st MT and proximal phalanx is normally <15 degrees.
  - Intermetatarsal angle (IMA): Between long axis of 1st and 2nd metatarsal is normally <9 degrees.
  - Distal metatarsal articular angle (DMAA): Between 1st metatarsal long axis and line through base of distal articular cap is normally <15 degrees.
  - Hallux valgus interphalangeus: Between long axis of distal phalanx and proximal phalanx is normally <10 degrees.

TREATMENT

- Primary indication for treatment is pain.
- There are conservative (nonoperative) and surgical approaches.
- Only surgical approaches can correct the hallux valgus deformity.
- Surgical treatment is generally more effective in improving pain but has attendant risks.

GENERAL MEASURES

- Nonoperative treatment options may improve symptoms and delay the progression of hallux valgus deformity, although high-quality evidence is limited:
  - Proper fitting footwear: low-heeled, wide-toe shoes to decrease stress on MTP joint (i.e., wide toe box)
  - Orthotics: correct foot alignment (pes planus and overpronation). Improving gait may prevent bunion formation and reduce pressure on the MTP.
  - Night splinting: in theory, stabilizes and balances soft tissue structures around the MTP. Limited evidence shows improvement in degree of angulation in mild hallux valgus.
  - Manual and manipulative therapy (MMT) stretches contracted soft tissue.
  - Foot exercises and stretching may improve intrinsic foot muscle strength and increase range of motion.
  - Pads/spacers: Pads decrease friction on the MTP joint. A toe spacer in the 1st interdigital space may reduce pain (1)[C].

MEDICATION

- Topical and oral medications (NSAIDs) can be used to relieve pain and swelling. Other topical options include capsaicin cream.
- Corticosteroid injections may improve pain (rarely used).

ADDITIONAL THERAPIES
Custom orthoses are a safe intervention that may decrease pain at 6 and 12 months compared with no treatment; however, this improvement is less than that seen with surgical intervention (2)[B].

**SURGERY/OTHER PROCEDURES**
- Surgery is indicated for patients with severe pain, dysfunction, or persistent symptoms that do not abate with conservative therapy.
- >100 different surgical techniques exist to treat hallux valgus.
  - No technique is proven superior; no universally accepted standard exists for procedure selection.
  - Minimally-invasive techniques are gaining popularity.
  - Choice of technique depends on disease severity, radiographic findings, and patient/surgeon-specific factors:
    - Arthrodesis: fusion of the 1st MTP joint; used for severe and/or recurrent hallux valgus; fusion of the 1st TMT joint (modified Lapidus) is considered for TMT joint hypermobility.
    - Arthroplasty: removing the joint or replacing it with a prosthesis; high revision rates
    - Exostectomy/bunionectomy: removing the medial bony prominence of the MTP joint
    - Soft tissue realignment: alters the function of surrounding ligaments and tendons; used for minor deformities or as an adjunct to bony correction techniques
    - Osteotomy and realignment: various techniques; can correct large deformities, but evidence of long-term outcome is lacking (3)[C]
    - Mini-tight rope procedure: use of a FiberWire to correct the misalignment of the deformity
- Some patients may have little to no improvement in symptoms despite interventions. Providers should establish realistic expectations prior to surgery.
- In pediatric patients, surgery should generally be delayed until skeletal maturity (4)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Marigold ointment may reduce pain and soft tissue swelling related to bunion.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Postoperative treatment includes physical therapy, physiotherapy, supportive footwear, continuous passive motion, or manual manipulation.
- Time until full weight-bearing depends on the surgical procedure.

**PROGNOSIS**
Patient outcome varies depending on biomechanical factors, severity of the deformity, and treatment modality used. The radiologic HA angle predicts surgical outcomes. Patients with an HA angle <37 degrees have a higher chance of having the deformity successfully corrected with surgery compared with patients with an HA angle >37 degrees (5)[B].

**COMPLICATIONS**
- Risks associated with surgery include infection, persistent pain, and poor cosmetic result.
- Additional risks vary with the surgical procedure.
Other complications may include:
- Early swelling
- Hallux varus
- Recurrence of bunion
- Metatarsal fracture
- Decreased sensation over the 1st metatarsal or phalanx

REFERENCES

ADDITIONAL READING

CODES

ICD10
- M20.10 Hallux valgus (acquired), unspecified foot
- M20.11 Hallux valgus (acquired), right foot
- M20.12 Hallux valgus (acquired), left foot

CLINICAL PEARLS

- Avoid footwear with high heels, pointed toe boxes, or inadequate toe space to reduce development or progression of bunions.
- Surgery generally results in superior outcomes for pain relief in appropriately selected patients.
- No single surgical method has shown to be superior for long-term pain relief.
- Establish realistic expectations prior to surgery to improve patient satisfaction with surgical outcomes.
**BURNS**
Caleb J. Mentzer, DO ● Cragin D. Currence, MD ● James R. Yon, MD

---

**BASICS**

**DESCRIPTION**
- Tissue injuries caused by application of heat, chemicals, electricity, or irradiation
- Extent of injury (depth of burn) is a result of intensity and duration of exposure.
  - 1st degree involves superficial layers of epidermis.
  - 2nd degree involves varying amounts of epidermis (with blister formation) and part of the dermis.
  - 3rd degree involves destruction of all skin elements (full thickness) with coagulation of subdermal plexus.
- System(s) affected: endocrine/metabolic, pulmonary, skin/exocrine

**Geriatric Considerations**
- Prognosis is worse for severe burns.
- Patients >60 years of age account for 11% of all burns.

**Pediatric Considerations**
Consider child abuse or neglect when dealing with hot water burns in children; abuse accounts for 15% of pediatric burns. Special concerns are sharply demarcated wounds, immersion injuries, and suspect stories. Involve child welfare services early.

**EPIDEMIOLOGY**
- Predominant age: 30 years; 13% infants; 11% >60 years of age
- Predominant gender: Males account for 70%.

**Incidence**
Per year in the United States
- 1.2 to 2.0 million burns; 700,000 emergency room visits; 45,000 to 50,000 hospitalizations;
  3,900 deaths owing to burn-related complications
- In children: 250,000 burns; 15,000 hospitalizations; 1,100 deaths
- Estimated total cost of $2 billion annually for burn care
- House fires cause 75% of deaths.
- Burn deaths decreasing nationally due to improved prevention and treatment
- Increase in burns from the illegal production of methamphetamines. Patients can present with a combination of chemical burn, thermal burn, and explosion injury.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Open flame and hot liquid are the most common causes of burns (heat usually ≥45°C): flame burns more common in adults; scald burns are more common in children.
- Caustic chemicals or acids (may show little signs or symptoms for the first few days)
- Electricity (may have significant injury with very little damage to overlying skin)
- Excess sun exposure
RISK FACTORS
• Water heaters set too high
• Workplace exposure to chemicals, electricity, or irradiation
• Young children and older adults with thin skin are more susceptible to injury.
• Carelessness with burning cigarettes: related to 18% of fatal fires in 2006
• Inadequate or faulty electrical wiring
• Lack of smoke detectors: Lacking or nonfunctioning smoke alarms are implicated in 63% of residential fires.
• Arson: cause of 12.4% of fires that resulted in fatalities in 2012

GENERAL PREVENTION
Home safety education should be a key mechanism for injury prevention.
• Families educated on home safety were more likely to have safe hot water temperatures.
• Safety education results in more families having functioning smoke alarms and increased use of fireguards.

COMMONLY ASSOCIATED CONDITIONS
Smoke inhalation syndrome
• May involve thermal burn to respiratory mucosa (e.g., trachea, bronchi) as well as carbon monoxide inhalation
• Occurs within 72 hours of burn
• Should be suspected in all burns occurring in an enclosed space or exposure to explosions

DIAGNOSIS
HISTORY
• History of source of burn
• In children or elderly: Check for consistency between the history and the burn’s physical characteristics.

PHYSICAL EXAM
• 1st degree: erythema of involved tissue, skin blanches with pressure; skin may be tender.
• 2nd degree: Skin is red and blistered; skin is very tender.
• 3rd degree: Burned skin is tough and leathery; skin is nontender.
• Rule of 9s
  – Each upper extremity: adult and child 9%
  – Each lower extremity: adult 18%; child 14%
  – Anterior trunk: adult and child 18%
  – Posterior trunk: adult and child 18%
  – Head and neck: adult 10%; child 18%
• Quick estimate: The surface area of the patient’s hand (palmar surface plus fingers) is 1% of the body surface area (BSA).
• Careful documentation of extent of burn and the estimated depth of burn
• Check for any signs suggestive of potential airway involvement: singed nasal hair, facial burns, carbonaceous sputum, progressive hoarseness, inflamed oropharynx, circumferential burns around the neck, tachypnea.
DIAGNOSTIC TESTS & INTERPRETATION
- Children: glucose (hypoglycemia may occur in children because of limited glycogen storage)
- Smoke inhalation: arterial blood gas, carboxyhemoglobin
- Electrical burns: ECG, urine myoglobin, creatine kinase isoenzymes

Initial Tests (lab, imaging)
- Labs: hematocrit; type and crossmatching; electrolytes, including BUN and creatinine; urinalysis
- Imaging: chest radiograph; xenon scan is useful in suspected smoke inhalation.

Diagnostic Procedures/Other
Bronchoscopy may be necessary in smoke inhalation to evaluate lower respiratory tract (1)[A].

TREATMENT
- Prehospital care
  - Remove the patient from the source of burn.
  - Extinguish and remove all burning clothing.
  - Room-temperature water may be poured onto burn but only in the first 15 minutes following burn exposure.
  - Wrap patient to prevent hypothermia.
  - All patients to receive 100% oxygen via face mask
- Hospitalization for all serious burns
  - 2nd-degree burns >10% of BSA
  - Any 3rd-degree burn
  - Burns of hands, feet, face, or perineum
  - Electrical or lightning burns
  - Inhalation injury
  - Chemical burns
  - Circumferential burn
- Transfer to burn center for (2)[C]
  - 2nd- and 3rd-degree burns >10% of BSA in patients <10 years and >50 years of age
  - 2nd-degree burns >20% of BSA and full-thickness burns >5% BSA in any age range
  - 3rd-degree burns in any age group
  - Burns of hands, feet, face, or perineum
  - Electrical or lightning burns
  - Inhalation injury
  - Chemical burns
  - Circumferential burn
  - Burns in patients with additional trauma (fractures, etc.) in which the burn is the more severe injury; otherwise, send to trauma center for stabilization
  - Burn injuries in patients with preexisting medical conditions that could affect management, mortality, or recovery

GENERAL MEASURES
- Based on depth of burns and accurate estimate of total BSA involved (rule of 9s)
- Tetanus prophylaxis (if not current)
● Remove all rings, watches, and other items from injured extremities to avoid tourniquet effect.
● Remove clothing and cover all burned areas with dry sheets.
● Flush area of chemical burn (for ~2 hours).
● For all major burns, use 100% oxygen administration; consider early intubation.
● Do not apply ice to burn site.
● Nasogastric tube (high risk of paralytic ileus)
● Foley catheter
● Analgesia
● ECG monitoring in first 24 hours following electrical burn
● Whirlpool hydrotherapy followed by silver sulfadiazine (Silvadene) occlusive dressings in severe burns
● Daily or BID cleansing with dressing changes
● Burn fluid resuscitation
  − Calculate fluid resuscitation from time of burn, not from time treatment begins.
  − 2 to 4 mL lactated Ringer × body weight (kg) × % BSA burn (1/2 given in first 8 hours, in second 8 hours, and in third 8 hours); in children, this is given in addition to maintenance fluids and is adjusted according to urine output and vital signs. Protocol-based resuscitation leads to superior outcomes.
  − Colloid solutions are not recommended during the first 12 to 24 hours of resuscitation [3] [A].
  − Other: Use of biologic membranes or skin substitutes may be indicated for burn coverage.
● Inhalation injury
  − Intubation, ventilation with positive end-expiratory pressure assistance. Employ lung protective ventilation strategies.
  − Hyperbaric oxygen treatment may be useful in patients with carbon monoxide levels >25%; patients with coma, focal neurologic deficit, ischemic ECG changes; and pregnant patients.
  − Prophylactic antibiotics and steroids are not indicated [4][C].

MEDICATION
First Line
● IV morphine or hydromorphone (Dilaudid) for severe pain
● Oral analgesics, such as acetaminophen (Tylenol) with codeine, acetaminophen with oxycodone (Percocet), or acetaminophen with hydrocodone (Lortab) for moderate pain
● Silver sulfadiazine (Silvadene): Apply topically to burn site (can cause leukopenia). Do not use in sulfonamide-allergic patients, women who are pregnant/breastfeeding, or infants (<2 months).
● Neosporin or bacitracin ointment: Apply to facial burns.
● Mupirocin: has potent inhibitory activity against methicillin-resistant Staphylococcus aureus (MRSA)
● Acticoat A.B. (a dressing consisting of two sheets of high-density polyethylene mesh coated with nanocrystalline silver) has a more controlled, prolonged release of silver, allowing less frequent dressing changes.
● Electrical burn with myoglobinuria will require alkalinization of urine and mannitol.
● Consider H₂ blockers (e.g., famotidine) or proton pump inhibitors (e.g., lansoprazole, pantoprazole) for stress ulcer prophylaxis in severely burned patients.
● Tetanus toxoid/tetanus immunoglobulin
● There is no clear indication for prophylactic systemic antibiotics.
Use of negative pressure wound therapy may result in a low-protease environment with higher levels of angiogenic factor (vascular endothelial growth factor [VEGF]) during wound healing, leading to more chaotic, hyperkeratinized, thickened epidermis when compared with a standard hydrocolloid dressing.

**Second Line**
- Mafenide (Sulfamylon) for full-thickness burn, best against Pseudomonas (caution: metabolic acidosis, painful)
- Silver nitrate 0.5% (messy, leeches electrolytes from burn, causes water toxicity)
- Povidone-iodine (Betadine) may result in iodine absorption from burn and “tan eschar,” makes débridement more difficult.
- Travase (enzymatic débridement)

**SURGERY/OTHER PROCEDURES**
- Escharotomy may be necessary in constricting circumferential burns of extremities or chest due to compartment syndrome.
- Tangential excision with split-thickness skin grafts: Early excision of burns results in a significant reduction in mortality (excluding patients with inhalational injury) and a significant decrease in hospital length of stay (5)[B].
- Various dressings (e.g., biosynthetic, biologic) are available to help reduce the number of dressing changes and promote healing.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Early mobilization is the goal.

**DIET**
- High-protein, high-calorie diet when bowel function resumes
- Nasogastric tube feedings may be required in early postburn period.
- Total parenteral nutrition if NPO is expected for >5 days
- Early initiation of enteral nutrition in the first 24 hours of admission results in shorter intensive care unit (ICU) stay and lower wound infection rates.

**PATIENT EDUCATION**
- Use of sunscreen: Skin grafts or newly epithelialized skin is highly sensitive to sun exposure and thermal extremes.
- Prevent access to electrical cords/outlets.
- Isolate household chemicals.
- Use low-temperature setting for water heater (<54°C).
- Household smoke detectors with special emphasis on maintenance
- Family/household evacuation plan
- Proper storage and use of flammable substances

**PROGNOSIS**
1st-degree burn: complete resolution
2nd-degree burn: epithelialization in 10 to 14 days (deep 2nd-degree burns probably will require skin graft)
3rd-degree burn: no potential for reepithelialization; skin graft is required.
Baux score (sum of age and TBSA burned) and Denver 2 score (pulmonary score ranging 0 to 3, using PaO$_2$/FiO$_2$ cutoffs of 100, 175, and 250), renal score (0 to 3, using creatinine cutoffs of 1.8, 2.5, and 5.0 mg/dL), hepatic score (0 to 3, using bilirubin cutoffs of 2, 4, and 8 mg/dL), and cardiac score (0 to 3, based on number and dosage of inotropes) can be used to estimate mortality (6)[B].

Length of hospital stay and need for ICU care depend on extent of burn, smoke inhalation, comorbidities, and age.
Burn size is correlated to complications; >60% TBSA burned in children and >40% in adults are at increased risk for mortality and morbidity (6)[B].
A 50% survival rate can be expected with a 62% burn in patients aged 0 to 14 years, 63% burn in patients aged 15 to 40 years, 38% burn in patients aged 40 to 65 years, and 25% burn in patients >65 years of age.
90% of survivors can be expected to return to an occupation comparable to their preburn employment.

COMPLICATIONS
Gastroduodenal ulceration (Curling ulcer)
Marjolin ulcer: malignant squamous cell carcinoma developing in old burn site
Signs of infection: discoloration, green fat, edema, eschar separation, and conversion of 2nd-degree to 3rd-degree wound
Biopsy is the best way to diagnose wound infection.
Burn wound sepsis: most commonly S. aureus (including MRSA), vancomycin-resistant enterococci, and gram-negative organisms
Pneumonia
Decreased mobility with possibility of future flexion contractures
Hypertrophic scarring common with burns

REFERENCES
CODES

ICD10
- T30.0 Burn of unspecified body region, unspecified degree
- T30.4 Corrosion of unspecified body region, unspecified degree

CLINICAL PEARLS
- 1st degree: erythema of involved tissue; skin blanches with pressure. Skin may be tender.
- 2nd degree: Skin is red and blistered. Skin is very tender.
- 3rd degree: Burned skin is tough and leathery. Skin is not tender.
BURSITIS, PES ANSERINE (PES ANSERINE SYNDROME)
Jennifer B. Schwartz, MD

BASICS

DESCRIPTION
● The pes anserinus (“goosefoot”) is the combined insertion of the sartorius, gracilis, and semitendinosus tendons on the anteromedial tibia.
● The pes anserine muscles help flex the knee and resist valgus stress.
● The pes anserine bursa lies between the semitendinosus tendons and the tibial attachment of the medial collateral ligament.
● Pes anserine syndrome is due to irritation of the bursa and/or tendons in this area.

EPIDEMIOLOGY

Incidence
Inflammation of the pes anserine bursa is detected in up to 2.5% of magnetic resonance imaging (MRI) studies of patients with knee pain. The overall incidence is likely higher.

ETIOLOGY AND PATHOPHYSIOLOGY
Pes anserine bursitis occurs due to:
● Overuse injury
● Excessive valgus and rotary stresses
● Mechanical forces and degenerative changes
● Direct trauma

RISK FACTORS
● Obesity, age, female gender (common in middle age, overweight females)
● Osteoarthritis, medial meniscal tears
● Pes planus; genu valgum
● Long distance running, hill running
● Swimming (“breaststroker’s knee”); cycling
● Sports with side-to-side/cutting activity (soccer, basketball, racquet sports)

COMMONLY ASSOCIATED CONDITIONS
● Osteoarthritis (OA)
  – Increased incidence of pes bursitis in patients with severe OA (>90% association with OA in one study)
  – Higher grades of OA associated with a thicker pes anserine bursa and larger area of bursitis
● Valgus knee deformity
● Obesity, female gender
● Diabetes mellitus (questionable association)

DIAGNOSIS
HISTORY
- Medial knee pain is the most common complaint.
- Pain is located 4 to 6 cm distal to the medial joint line on the anteromedial aspect of the tibia.
- Pain exacerbated by knee flexion:
  - Going up or down stairs
  - Getting out of a chair
  - Sitting cross-legged

PHYSICAL EXAM
- Common findings include:
  - Tenderness to palpation at the pes anserine insertion
    - 30% of asymptomatic patients will have tenderness to deep palpation in this area.
  - Pain worsens with flexion of the knee against resistance.
  - Localized swelling of the pes anserine insertion
- Findings that suggest an alternative diagnosis: joint effusion, tenderness directly over the joint line, erythema or warmth, locking of the knee, systemic signs such as fever or pain with passive knee movement

DIFFERENTIAL DIAGNOSIS
- Medial collateral ligament injury
- Medial meniscal injury
- Medial plica syndrome
- Medial compartment OA
- Semimembranosus bursitis
- Popliteal/meniscal cyst
- Tibial stress fracture
- Septic arthritis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Primarily a clinical diagnosis
- Lab work not indicated
- Imaging is not indicated unless there is concern for underlying bony injury/fracture, ligamentous injury, or meniscal tear.

Follow-Up Tests & Special Considerations
- X-ray
  - Can demonstrate underlying osteoarthritis
- Ultrasound (US)
  - Can demonstrate focal edema within the pes anserine bursa but has poor correlation with clinical findings
  - Many patients with the clinical diagnosis of pes anserine bursitis have no morphologic changes of the pes anserine complex on US.
- MRI: can demonstrate inflammation of the bursa and delineate the pes anserine bursa from other structures. T2-weighted axial images are best on MRI.
  - No large studies have evaluated the correlation between the clinical diagnosis of pes anserine bursitis and radiographic evidence of pes anserine pathology on MRI.
– May see fluid in the pes bursa on MRI in 5% of asymptomatic patients

**TREATMENT**

Pes anserine bursitis is often self-limited. Conservative therapy is most common:

- Relative rest and activity modification to avoid offending movements (especially knee flexion)
- Ice to the affected area
- Kinesio taping (2)[B]
- Physical therapy for knee strengthening and range of motion activities
- Nonsteroidal anti-inflammatory drug NSAIDs for pain control
- Corticosteroid injection
- Weight loss to improve biomechanical forces at the knee
- Extracorporeal shock wave therapy

**MEDICATION**

**First Line**

- NSAIDs, such as ibuprofen (800 mg PO TID) or naproxen (500 mg PO BID), are common first-line therapy.
- Physical therapy and treatment of underlying knee pathology also important for recovery
  - One study showed kinesiotaping to be more effective than physical therapy + naprosyn (2) [C]

**Second Line**

- Corticosteroid injection combined with local anesthetic provides relief in many patients.
  - Inject at the point of maximal tenderness using standard aseptic technique.
  - ~2 mL of anesthetic (i.e., 1% lidocaine) and 1 mL of steroid (i.e., 40 mg of methylprednisolone) is injected into the bursa using a small (e.g., 25-gauge, 1-inch) needle.
  - Insert needle perpendicular to the skin until bone is felt and then withdraw slightly before injecting.
  - Avoid injecting directly into the tendon
- US-guided injection is superior to blind injection (3)[C].
- Platelet-rich plasma injections can provide pain relief (4)[C].
- Extra corporeal shock wave therapy (ESWT) can also decrease pain in best bursitis (5)[C].

**ADDITIONAL THERAPIES**

- Hamstring and Achilles stretching
- Quadriceps strengthening—particularly of the vastus medialis (terminal 30 degrees of knee extension)
- Adductor strengthening

**SURGERY/OTHER PROCEDURES**

- No role for surgery in routine isolated cases
- Drainage or removal of bursa may be used in severe/refractory cases.

**ONGOING CARE**
Home exercise program focusing on flexibility and strengthening

**DIET**
Consider dietary changes as part of a comprehensive weight-loss program if obesity is a contributing factor.

**PROGNOSIS**
Most cases of pes anserine syndrome respond to conservative therapy. Recurrence is common, and multiple treatments may be required.

**REFERENCES**

**ADDITIONAL READING**

**CODES**
**ICD10**
- M70.50 Other bursitis of knee, unspecified knee
- M70.51 Other bursitis of knee, right knee
- M70.52 Other bursitis of knee, left knee
CLINICAL PEARLS

- Consider pes anserine syndrome in patients presenting with medial knee pain.
- Pes anserine syndrome is relatively common in athletes and in older, obese patients with OA.
- Tenderness over the insertion of the pes anserine tendon on the medial aspect of the tibia 4 to 6 cm distal to the joint line is common in asymptomatic patients as well—correlation of the entire clinical picture is necessary for accurate diagnosis.
- Consider pes anserine syndrome in patients who have persistent symptoms associated with medial-sided OA.
- Treatment is typically conservative. A local steroid/anesthetic injection may provide pain relief and enhance rehabilitation.
**BASICS**

**DESCRIPTION**

- Heterogeneous mucocutaneous infection with commensal Candida species
- Characterized by superficial infection of the skin, mucous membranes, and nails
- >20 Candida species cause infection in humans. Candida albicans is most common (80% of isolates).
  - Candida auris is an emerging global pathogen with a high propensity to develop drug resistance (1).
- Candidiasis affects:
  - Aerodigestive system
    - Oropharyngeal candidiasis (thrush): mouth, pharynx
    - Angular cheilitis: corner of the mouth
    - Esophageal candidiasis
    - Gastritis and/or ulcers, associated with thrush; alimental or perianal
  - Other systems
    - Candida vulvovaginitis: vaginal mucosa and/or vulvar skin
    - Candidal balanitis: glans of the penis
    - Candidal paronychia: nail bed or nail folds
    - Folliculitis
    - Interdigital candidiasis: webs of the digits
    - Candidal diaper dermatitis and intertrigo (within skin folds)
- Synonym(s): monilia; thrush; yeast; intertrigo

**ALERT**

Vaginal antifungal creams and suppositories can weaken condoms and diaphragms.

**Pregnancy Considerations**

- Vaginal candidiasis is common during pregnancy.
- Extend topical treatment during pregnancy by several days (typically a full 7-day course).
- Vaginal yeast infection at birth increases the risk of newborn thrush but is of no overall harm to baby.

**EPIDEMIOLOGY**

- Common in the United States; particularly with immunodeficiency and/or uncontrolled diabetes
- Age considerations
  - Infants and seniors: thrush and cutaneous infections (infant diaper rash)
  - Women of childbearing age: vaginitis
  - Prepubertal or postmenopausal: yeast vaginitis
- Predominant sex: female > male

**Incidence**
Unknown—mucocutaneous candidiasis is common in immunocompetent patients. Complication rates are low.

**Prevalence**
Candida species are normal flora of oral cavity, pharynx, esophagus, and gastrointestinal (GI) tract that are present in >70% of the U.S. population.

**ETIOLOGY AND PATHOPHYSIOLOGY**
C. albicans (responsible for 80–92% vulvovaginal and more than 80% of oral isolates). Altered cell–mediated immunity against Candida species (either transient or chronic) increases susceptibility to infection.

**Genetics**
Chronic mucocutaneous candidiasis is a heterogeneous, genetic syndrome with infection of skin, nails, hair, and mucous membranes; typically presents in infancy

**RISK FACTORS**
- Immune suppression (antineoplastic treatments, transplant patients, cellular immune defects)
- Malignant diseases
- AIDS or hematologic/immune disorders (neutropenia)
- Corticosteroid use
- Smoking and alcoholism
- Hyposalivation (Sjögren disease, drug-induced xerostomia, radiotherapy) (2)
- Broad-spectrum antibiotic therapy
- Douches, chemical irritants, and concurrent vaginitides alter vaginal pH and predispose patients to candidal vaginitis.
- Denture wear, poor oral hygiene (2)
- Birth control pills, intrauterine devices
- Endocrine alterations (diabetes mellitus, pregnancy, renal failure, hypothyroidism)
- Uncircumcised men at higher risk for balanitis

**GENERAL PREVENTION**
- Use antibiotics and steroids judiciously; rinse mouth after using inhaled steroids.
- Avoid douching.
- Treat other vaginal infections.
- Minimize perineal moisture (wear cotton underwear; frequent diaper changes).
- Clean dentures often; use well-fitting dentures and remove during sleep.
- Optimize glycemic control in diabetics.
- Preventive regimens during cancer treatments, especially in patients with hematologic malignancies (3)
- Treat with highly active antiretroviral therapy in HIV-infected patients.
- Antifungal prophylaxis against oral candidiasis is not recommended in HIV-infected adults unless patients have frequent or severe recurrences.

**COMMONLY ASSOCIATED CONDITIONS**
- HIV
- Leukopenia
- Diabetes mellitus
Cancer and other immunosuppressive conditions

DIAGNOSIS

HISTORY

Infants/children
- Oral: adherent white patches on oral mucosae or on the tongue that do not wipe away easily
- Perineal: erythematous rash with characteristic satellite lesions; painful if skin layer eroded. 40–75% of diaper rashes >3 days are C. albicans.
- Angular cheilitis: painful fissures at mouth corners

Adults
- Vulvovaginal lesions; whitish “curd-like” discharge; pruritus; burning
- Balanitis: erythema, erosions, scaling; dysuria

Immunocompromised hosts
- Oral: white, raised, painless, distinct patches; red, slightly raised patches/petechiae
- Esophagitis: dysphagia, odynophagia, retrosternal pain; usually concomitant thrush
- GI symptoms: abdominal pain
- Folliculitis: follicular pustules

PHYSICAL EXAM

Infants/children
- Oral: white, raised, distinct patches within the mouth; when wiped off, reveals red base
- Perineal: erythematous maculopapular rash with satellite pustules or papules
- Angular cheilitis: tender fissures in mouth corners, often cracked and bleeding

Adults
- Vulvovaginal: thick, whitish, cottage cheese–like discharge; vagina or perineum erythema
- Balanitis: erythema, linear erosions, scaling
- Interdigital: redness, excoriation at base and web spaces of fingers and/or toes, possible maceration

Immunocompromised hosts
- Oral: white, raised, non-tender, distinct patches; red, slightly raised patches; thick, dark-brownish coating; deep fissures (2)
- Esophagitis: Often, oral thrush is visible.
- Folliculitis: follicular pustules
- Interdigital: redness, excoriation at base of fingers and/or toes, often maceration

DIFFERENTIAL DIAGNOSIS

For oral candidiasis
- Leukoplakia; lichen planus; geographic tongue
- Herpes simplex; erythema multiforme
- Pemphigus

Baby formula or breast milk can mimic thrush—easier to remove than thrush (no red base when wiped away).

Hairy leukoplakia: does not rub off; dorsum and lateral margins of tongue

Angular cheilitis from vitamin B or iron deficiency, staphylococcal infection, or edentulous overclosure
- Bacterial vaginosis and Trichomonas vaginalis tend to have more odor, itch, and a different discharge.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- 10% potassium hydroxide (KOH) slide preparation: mycelia (hyphae) or pseudomycelia (pseudohyphae) yeast forms; few white blood cell or 15–30% NaOH (4,5)[A]
- Associated with normal vaginal pH (<4.5)
- Barium swallow: cobblestone appearance, fistulas, or dilatation (denervation)

**Diagnostic Procedures/Other**
- If first-line treatment fails, obtain samples for culture.
- Sabouraud dextrose agar for fungal growth (4)[A]
- Biopsy of hyperplastic candidiasis (4)[A]
- Esophagitis may require endoscopy with biopsy (if suspicious for cancer).
- HIV-seropositive patients with thrush and dysphagia relieved by antifungal have Candida esophagitis.

**Test Interpretation**
Biopsy: epithelial parakeratosis with polymorphonuclear leukocytes in superficial layers; periodic acid–Schiff staining reveals candidal hyphae (4,5)[A].

**TREATMENT**

**GENERAL MEASURES**
Screen for immunodeficiency (diabetes, HIV, autoimmune disease).

**MEDICATION**

**First Line**
- Vaginal (choose 1)
  - Miconazole (Monistat) 2% cream: one applicator or 200 mg (one suppository), intravaginally QHS for 7 days
  - Clotrimazole (Gyne-Lotrimin, Mycelex): intravaginal suppository (100 mg QHS for 7 days; 200 mg QHS for 3 days; 500 mg daily for 1 day) or 2% cream (one applicator QHS for 3 days)
  - Fluconazole 150 mg PO single dose
- Oropharyngeal
  - Mild disease
    - Clotrimazole (Myclex): oral 10-mg troche; 20 minutes 5 times daily for 7 to 14 days
    - Nystatin suspension: 100,000 U/mL swish and swallow 400,000 to 600,000 U 4 times per day
  - Nystatin pastilles: 200,000 U each, QID daily for 7 to 14 days (5)[A]
    - Nystatin ointment: 100,000 U/g under denture and corners of mouth for 3 weeks
    - Remove dentures at night; clean 2 times weekly with white vinegar, 0.1% hypochlorite solution, or chlorhexidine gluconate (2% suspension) (2).
– Moderate to severe disease
  o Fluconazole: 200 mg load and then 100 to 200 mg (>14 days of age: 6 mg/kg × 1 dose
    and then 3 mg/kg q24h × 7 to 14 days [max 100 mg/day])

**Esophagitis**
– Fluconazole: PO 400 mg load and then 200 to 400 mg/day for 14 to 21 days or IV 400 mg
  (6 mg/kg) daily if oral therapy not tolerated

**Pregnancy Considerations**
2% miconazole cream, intravaginally, for 7 days in uncomplicated candidiasis; systemic
amphotericin B for invasive candidiasis in pregnancy

**Second Line**

**Vaginal**
– Terconazole (Terazol): 0.4% cream (one applicator QHS for 7 days of induction therapy);
  0.8% cream/80-mg suppositories (one applicator or one suppository QHS for 3 days)
  - For recurrent cases (≥4 symptomatic episodes in 1 year): induction therapy with 10 to 14
days of topical or oral azole and then fluconazole 150 mg once per week for 6 months (5)
  [A]
  o In HIV patients: Concerns with this regimen include emergence of drug resistance (6)[A].

**Oropharyngeal**
– Miconazole oral gel (20 mg/mL): QID, swish and swallow.
– Itraconazole (Sporanox) suspension: 200 mg (20 mL) daily; swish and swallow for 7 to 14
days.
– Posaconazole (Noxafil) oral suspension: 400 mg BID for 3 days and then 400 mg daily for
  up to 28 days
– Amphotericin B (Fungizone) oral suspension (100 mg/mL): 1 mL QID daily, swish and
  swallow; use between meals.

**Esophagitis**
– Amphotericin B (variable dosing) IV dose of 0.3 to 0.7 mg/kg daily or an echinocandin
  should be used for patients who cannot tolerate oral therapy.
– For refractory disease:
  o Itraconazole (Sporanox) oral solution: 200 mg daily
  o Posaconazole (Noxafil) oral suspension: 400 mg BID
  o Voriconazole (Vfend) 100 to 200 mg q12h PO or IV for 14 to 21 days (5)[A]

**Continue treatments for 2 days after infection gone:**
– Contraindications
  o Ketoconazole, itraconazole, or nystatin (if swallowed): severe hepatotoxicity
  o Amphotericin B: can cause nephrotoxicity
– Precautions
  o Miconazole: can potentiate the effect of warfarin but drug of choice in pregnancy
  o Fluconazole: renal excretion: rare; hepatotoxicity: resistance frequent
  o Itraconazole: Doubling the dosage results in ~3-fold increase in itraconazole plasma
    concentrations.
– Possible interactions (rarely seen with creams, lotions, or suppositories)
  o Fluconazole
    o Rifampin: decreased fluconazole concentrations
    o Tolbutamide: decreased concentrations
Warfarin, phenytoin, cyclosporine: altered metabolism; check levels.
– Itraconazole: potent CYP3A4 inhibitor. Carefully assess all coadministered medications.
– Work in progress for a vaccine in patients with chronic mucocutaneous candidiasis (4)[A]

ISSUES FOR REFERRAL
• Evaluate patients with recurrent superficial candidal infections without obvious reasons, for immunodeficiency (6)[A].
• GI candidiasis

ADDITIONAL THERAPIES
• For infants with thrush: Boil pacifiers and bottle nipples; assess mother’s breasts/nipples for Candida infection.
• For denture-related candidiasis: Disinfect dentures (using soak solution of white vinegar, 2% chlorhexidine gluconate solution, or 0.1% hypochlorite solution) and treat orally.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Probiotics: Lactobacillus and Bifidobacterium may inhibit Candida spp.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Proper oral hygiene. Protocols for brushing, denture care, and oral cavity moistening reduce oral candidiasis.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Immunocompromised persons benefit from regular evaluation and screening.

DIET
Active culture yogurt or other live Lactobacillus may decrease colonization; indeterminate evidence

PATIENT EDUCATION
• Advise patients at risk for recurrence about potential for overgrowth with antibacterial therapy.
• “Azole” medications are pregnancy Category C.
• Polyene medications are pregnancy Category B; however, only give orally when benefits outweigh risks.

PROGNOSIS
• Benign prognosis in immunocompetent patients
• For immunosuppressed persons, Candida may become an AIDS-defining illness with significant morbidity.

COMPLICATIONS
In HIV patients, moderate immunosuppression (e.g., CD4 200 to 500 cells/mm³) may be associated with chronic candidiasis (6)[A]. With more severe immunosuppression (e.g., CD4 <100 cells/mm³), esophagitis or systemic fungal infections are possible.
REFERENCES

ADDITIONAL READING

SEE ALSO

Candidiasis, Invasive; HIV/AIDS

CODES

ICD10

- B37.9 Candidiasis, unspecified
- B37.0 Candidal stomatitis
- B37.49 Other urogenital candidiasis

CLINICAL PEARLS

- Candidiasis is typically a clinical diagnosis. KOH preparations are a simple confirmatory office test. Culture and biopsy are rarely needed.
- Person-to-person transmission is rare.
- If tongue pain continues after treatment, consider burning mouth syndrome. Obtain a biopsy if there is concern for oral cancer.
- Oral antifungal medications are hepatically metabolized and may have serious side effects.
CAPACITY (COMPETENCE) DETERMINATION AND INFORMED CONSENT
Jon S. Parham, DO, MPH, FAAFP ● Sandra N. New, DNP

BASICS
- Personal autonomy in decision making is a fundamental personal freedom.
- Capacity determination is an inherent element of the informed consent process.
- It is universally presumed that patients 18 years and older (or an emancipated minor under individual state laws) have legal and clinical capacity to give informed consent for health care testing, interventions, and treatment or to refuse same no matter the harm or benefit until proven otherwise.

DESCRIPTION
- Capacity:
  - A clinical evaluation; determined by an authorized health care provider
  - Focuses on perceived ability of patient to participate in informed consent
- Competence:
  - A legal determination of abilities, performed by a court judge
  - Involves medical information, but not limited to medical issues
- Capacity is the currently preferred term to competence: Legal Capacity and Medical Capacity
- A capacity determination is needed when arriving at a health care decision for testing, treatment, or an intervention involving risk of serious harm or no improvement.
  - Any treating health care provider can evaluate capacity, including the provider also obtaining informed consent or a psychiatrist or neuropsychiatric consultant
- Medical capacity is determined by:
  - Clinical observation and response to questions
  - Capacity assessment tool(s)
  - Cognitive assessment tool
  - Interviews with a guardian or designated health care power of attorney (if indicated)
- The four “C”s of capacity are:
  - Context: comprehension of their health status
  - Choices: able to describe options
  - Consequences: able to explain possible outcomes
  - Consistency: continuity of choice selection (1)[C]
- Adequate cognition is a fundamental component, but not the sole determinant of capacity.

EPIDEMIOLOGY
Being near “end of life” increases the chance of having an advanced directive:
- Among almost 800,000 U.S. adults studied, approximately 1/3 have completed an advanced directive (2).
- As many as 1/3 of seriously ill geriatric patients near end of life do not have advanced directives (3).

Incidence
Need for capacity determination has been increased due to:
• Increasing patient longevity
• Prolonged chronic disease states
• Better patient rehabilitation opportunities
• Safer anesthetics and advanced postsurgery care

**Prevalence**
Prevalence varies based on the patient risk factors (pretest probability) and physician experience:
• Only 2.8% of healthy outpatient seniors were found to lack capacity (4).
• Among >3,700 geriatric hospital patients near end of life requiring health care decisions, only 30% demonstrated capacity to make those decisions (5).
• Highest rate of incapacity is in patients with a learning disability.

**ETIOLOGY AND PATHOPHYSIOLOGY**
• Dementia is the most likely cause for individuals to be found incapable of making health care decisions in the outpatient setting.
• Capacity is a dynamic state; reassessment is necessary with each significant health care decision and informed consent.

**RISK FACTORS**
• For incapacity:
  – Longevity, multiple comorbidities, in hospital for medical reasons
  – Never married, never worked outside home
• Insufficient informed consent:
  – Patient factors:
    o Health illiteracy
    o Language and cultural barriers
    o Excessive information
  – Provider factors:
    o Inexperience with process (e.g., house staff)
    o Insufficient discussion time
    o Use of medical terminology

**GENERAL PREVENTION**
Early assessment and periodic reassessment of capacity in:
• Dynamic patient conditions, like electrolyte imbalance, closed head injuries, delirium states
• After procedures with anesthesia or analgesics
• Enhancement and dissipation of mind-altering substances

**COMMONLY ASSOCIATED CONDITIONS**
• Dementia/Alzheimer disease, Parkinson disease, and traumatic brain injury
• Schizophrenia, depression, and substance abuse
• Acute illness, metabolic derangement

**DIAGNOSIS**
In patients without capacity, physicians are unable or unwilling to recognize the incapacity in 42% of cases (4).
HISTORY
Family or frequent observers are resources regarding behavior patterns and reasoning displayed by patients.

PHYSICAL EXAM
Verbal patient responses, facial expression, and body language often confirm capacity or are “alerts” for more formal evaluation.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Screening for capacity occurs with:
- Informal patient conversations
- Discussions inherent to medical history taking
- Informed consent discussions

Follow-Up Tests & Special Considerations
- Four common tools for the formal evaluation of capacity
  - MacArthur Competence Assessment Tool-Treatment (MacCAT-T)—gold standard
    - Assesses: understanding, reasoning, appreciation, expression of choice
    - Semi structured interview, 20 minutes
  - Aid to Capacity Evaluation (ACE)
    - Semi structured interview, 7 questions
  - Assessment of Capacity for Everyday Decision-Making (ACED)
    - Semi structured interview
    - Used with cognitively impaired seniors to measure capacity to perform independent activities of daily living
  - Capacity Assessment Tool (CAT)
    - Structured interview
    - Assesses capacity to discern between two intervention choices (Scott D)

- Special situation/considerations for assessment of capacity for informed consent
  - Communication impairments
    - Translators of all languages, including for deafmute and blind combined with deafness
    - Health literacy level accommodation
  - Patient participation in research or experimental intervention protocols
  - Patient refusal to participate in informed consent
  - Child as patient

TREATMENT
GENERAL MEASURES
Steps to take if a patient fails to have capacity or fails to display ability to participate in informed consent:
- Determine the acuity of the need for decision making (e.g., decisions regarding emergency care—“loss of life or limb”—are made by treating provider).
- Correct any reversible causes of impaired capacity (e.g., electrolyte rebalance or language translation).
- Reframe questions that help determine capacity or simplify explanation in informed consent.
- Seek out next of kin to become a proxy decision maker with understanding of patient’s values.
- A court-appointed guardian process is lengthy and usually is not necessary.

**ISSUES FOR REFERRAL**
Specialist consultation is not usually necessary to determine capacity for medical decision making. As indicated, consider consulting with the following expert services:
- Psychiatry
- Neuropsychiatry
- Medical ethics
- Health care attorney

**ONGOING CARE**
The following have responsibility for medical decision making and informed consent when the patient does not have capacity:
- Spouse (unless legally separated)
- Adult child
- A parent
- An adult sibling
- An adult who has provided unique care and has a special knowledge of the patient values and is accessible (6)

**FOLLOW-UP RECOMMENDATIONS**
Reassessment of patient is a provider responsibility:
- At each significant medical decision point
- If the patient shows signs of change in capacity

**REFERENCES**

**ADDITIONAL READING**
- Baón-Pérez BS, Álvarez-Marrodán I, Navío-Acosta M, et al. Spanish validation of the

SEE ALSO

Advance Care Planning

CLINICAL PEARLS

- Use a structured approach to assessing decision-making capacity, including an assessment of language barriers, identification and remediation of reversible causes of incapacity, a comprehensive interview to assess consent, and the inclusion of appropriate formal assessment tools.
- Capacity is dynamic, so reassess at every significant health care decision/informed consent point.
- The order of succession for decision making is: spouse, adult child, parent, adult sibling, adult with close relationship.
- Integrate formal assessment of patient with severity of decision consequences into patient context for capacity determination.
**BASICS**

**DESCRIPTION**
- Carbon monoxide (CO) is an odorless, tasteless, colorless gas produced during the incomplete combustion of carbon-based compounds. If inhaled, CO may cause nonspecific symptoms and is potentially fatal.
  - CO inhalation leads to displacement of oxygen from binding sites on hemoglobin to form carboxy hemoglobin (COHb).
  - The formation of COHb leads to tissue hypoxia from decreased oxygen carrying capacity and a left shift of the oxyhemoglobin dissociation curve.
  - CO binds to mitochondrial cytochrome oxidase, impairing adenosine triphosphate (ATP) production. It also binds to myoglobin, affecting muscle function.
- System(s) affected: cardiovascular, pulmonary, musculoskeletal, nervous

**Pregnancy Considerations**
Tissue hypoxia due to CO poisoning may cause significant fetal abnormalities because CO has a stronger affinity and a longer half-life when bound to fetal hemoglobin. The fetus is therefore susceptible to adverse outcomes even if the mother is unaffected.

**EPIDEMIOLOGY**

**Incidence**
CO poisoning is the third leading cause of poisoning death in the United States.
- Accounts for 50,000 ER visits annually (16 cases per 100,000 population); 1–3% are fatal.
- Approximately 15,000 intentional poisoning occur per year, accounting for 2/3 reported deaths (10-fold higher than unintentional poisonings).
- Vague symptoms may cause patients to not seek care, leading to underdiagnosis.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- CO is rapidly absorbed through the lungs, binding hemoglobin with 210 to 240 times the affinity of oxygen. This stabilizes hemoglobin in the relaxed high affinity state (R state), reducing oxygen-carrying capacity and delivery, leading to left shift of the oxyhemoglobin dissociation curve.
- CO inactivates cytochrome oxidase. This leads to decreased ATP production, especially in tissues with high metabolic demands (brain, heart). The electron transport chain continues, generating superoxide radicals, leading to further damage.
- Increased peroxynitrite production contributes to impaired mitochondrial function and hypoxia.
- CO displaces NO from platelets, leading to platelet activation and aggregation. Oxidative stress, lipid peroxidation, and apoptosis are additional effects.
- Proteases released from neutrophil degranulation interact with xanthine hydrogenase forming xanthine oxidase. This inhibits endogenous defense against oxidative stress.
- Brain hypoxia leads to excitatory amino acid production and increased nitrite levels, resulting in further ischemia.
- CO also promotes the release of NO which can lead to profound hypotension.

**RISK FACTORS**
- Alcohol and tobacco use
- Closed or improperly ventilated spaces
- Fires and fire-related injuries
- High-risk vocations: coal miners, auto mechanics, paint stripping, work in the solvent industry
- Exposure to exhaust from motor vehicles, faulty furnaces, stoves, generator use (power outages and storms), and other fuel burning devices
- If exposed, infants, elderly patients, and patients with comorbid conditions such as cardiovascular disease, anemia, and chronic respiratory conditions have increased risk for poor outcomes.
- Increased endogenous CO production occurs in patients with hemolytic anemia.

**GENERAL PREVENTION**
- Appropriate ventilation around fuel-burning devices
- Installation of in-home CO monitors or alarms
- Postexposure determination of CO source to limit future exposures and/or eliminate source
- Public policy to ensure building code safety

**COMMONLY ASSOCIATED CONDITIONS**
- CO and cyanide poisoning often occur simultaneously after smoke inhalation and have synergistic effects.
- Intentional poisoning often occurs in the context of coingestion of other substances (~40%).
- Up to 50–75% of fire-related injuries have a component of CO poisoning.

**DIAGNOSIS**
- Clinical triad of (i) relevant symptoms, (ii) history of CO exposure, (iii) and elevated COHb levels (1)
- An elevated carboxyhemoglobin level of >3% in a nonsmoker and >10% in smokers confirms exposure. The COHb level does not correlate with the severity of the illness or long-term prognosis but is necessary for the diagnosis (1,2,3,4).
- Older pulse oximters do not differentiate COHb from oxyhemoglobin, with normal oximeter readings in a hypoxic patient (3). Eight-wavelength CO oximeters can detect CO exposure but cannot reliably make a definitive diagnosis of CO poisoning (1,2).

**HISTORY**
- The diagnosis of CO poisoning is dependent on duration and mechanism of exposure. No single symptom is sensitive or specific. A high index of suspicion is necessary.
- Common symptoms include
  - Headache (84% of patients)
  - Confusions/impaired judgment
  - Dizziness
  - Nausea/vomiting
- Fatigue
- Chest pain and shortness of breath

Patients may also present with visual disturbances, seizures, syncope, arrhythmias, and loss of consciousness.

Long-term (subacute) exposure defined as >24 hours and occurs with repeated exposure to low concentrations of CO. Symptoms include chronic fatigue, emotional distress, memory deficits, difficulty working, sleep disturbances, vertigo, neuropathy, recurrent infections, polycythemia, paresthesia, abdominal pain, and diarrhea.

- Exclude pregnancy in all female patients.

**PHYSICAL EXAM**

- Findings vary. Patients often report confusion or have altered mental status.
- Classically described “cherry red” skin coloring of lips and skin is rare (<1% of cases).
- Examine for signs of burns (enclosed space fires) or other secondary injuries.
- Full neurologic and mental status examinations; confusion/CNS depression, ataxia, visual field defects, papilledema, and nystagmus
- Respiratory depression or tachypnea, and cyanosis
- Tachycardia, hypotension, cardiac dysrhythmias

**DIFFERENTIAL DIAGNOSIS**

- Cyanide toxicity (also coexistent)
- Methylene chloride (dichloromethane) inhalation or ingestion
- Viral syndromes
- Behavioral disorders (major depressive disorder)
- Other causes of mental status changes:
  - Infections (meningitis or encephalitis)
  - Metabolic causes (hypoglycemia)
  - Alcohol intoxication, opiates, acetylsalicylic acid (ASA) overdose
  - Trauma
  - CNS lesions

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Diagnosis requires a recent history of CO exposure, consistent symptoms, and demonstration of an elevated COHb level.
- Noninvasive COHb measurement should not be used to diagnose CO poisoning (2)[A].
- Arterial or venous blood gas is recommended:
  - COHb levels of >3% in nonsmokers, >10% in smokers. COHb may be low despite significant poisoning (e.g., treatment with O₂ or significant time elapses before the level is drawn).
  - Significant metabolic acidosis; anion gap >16
  - Elevated lactate confers worse prognosis.
  - PaO₂ tends to be normal because O₂ dissolved in blood is not affected by CO.
- Basic labs: serum chemistries, CBC
- ECG in all patients
  - Cardiac enzymes in patients with moderate or severe poisoning. If elevated, there is an increased risk of mortality. Important for (2)[B]:
Follow-Up Tests & Special Considerations

- Consider CO poisoning in younger patients with chest pain or symptoms suggestive of ischemia.
- Consider the diagnosis in afebrile patients with vague or “flulike” symptoms. CO poisoning and the flu are both common during the winter time.
- Patients may present as a group (coworkers, family members, school children) with similar symptoms.
- Patients with intentional poisoning should undergo behavioral evaluation when stable.
- Implement suicide precautions if appropriate.

TREATMENT

GENERAL MEASURES

- Prompt removal from the CO source
- Supportive care as necessary
- Intubation and mechanical ventilation may be necessary for severe intoxication, particularly if the patient is unable to protect their airway or if there are signs of respiratory failure.
- Poison Control: 800-222-1222 (United States)

MEDICATION

100% oxygen via nonrebreathing reservoir facemask until COHb is normal (<3%) and patient is asymptomatic, regardless of oxygen saturation or \( PO_2 \) (1)[C],(2,4)[A]

ADDITIONAL THERAPIES

- The efficacy of hyperbaric oxygen (HBO\(_2\)) remains controversial; unclear whether HBO\(_2\) reduces the incidence of adverse neurologic outcomes compared to normobaric oxygen (NBO\(_2\)) alone (2,4,5)[A]
- NBO\(_2\) and HBO\(_2\) reduce the elimination half-life of COHb to ~85 minutes and 20 minutes, respectively (1).
- If HBO\(_2\) is unavailable, administer NBO\(_2\) until CO has normalized and symptoms have resolved (2,4,5)[A].
- HBO\(_2\) therapy may reduce permanent neurologic deficit by reversing inflammatory response and mitochondrial dysfunction (1)[C].
- Optimal HBO\(_2\) protocols are unclear (4)[C].
- HBO\(_2\) currently recommended for:
- Age >36 years (4)[C]
- Exposure >24 hours (4)[C]
- Levels >25% (1,4)[C]
- Loss of consciousness (1,4)[C]
- Abnormal neurologic or psychiatric signs (1)[C]
- Cardiovascular dysfunction (1)[C]
- Severe acidosis (1,4)[C]

Empirically treat patients for cyanide poisoning who present with CO poisoning from a house fire, if the pH is <7.20 or plasma lactate is >10 mmol/L (1,4)[C].

HBO₂ not as likely to be helpful if >24 hours has elapsed since exposure.

Expert consensus favors HBO₂ therapy for pregnant women (4)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients whose symptoms do not improve after 4 to 5 hours of 100% O₂ should be transported to the nearest HBO₂ facility. Hospitalize patients with severe poisoning, ECG or laboratory evidence of end-organ damage, and those with concerning medical or social factors.
- Admit unconscious patients with CO poisoning to ICU.
- Patients with accidental poisoning and mild symptoms that resolve in the ED can be safely discharged.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- All patients treated for acute CO poisoning should follow up in 1 to 2 months after discharge (1,4).
- If there are behavioral or cognitive concerns, pursue neuropsychological evaluation, particularly following intentional CO poisoning.
- Long-term cognitive, psychiatric, speech, occupational, and physical rehab may be necessary.

Patient Monitoring
Repeat measurement of COHb levels with arterial blood gases.

PATIENT EDUCATION

- Professional installation and maintenance of combustion devices
- Consumer Product Safety Commission hotline 1-800-638-2772
- CO detector in bedrooms and by potential CO sources
- Annual furnace inspections (6)[B]
- Avoid use of combustion engines indoors; periodic furnace inspection
- www.cdc.gov/co/default.htm

PROGNOSIS

Although most patients completely recover, chronic neuropsychiatric impairment is described in 12–68% of patients.

COMPLICATIONS

- High-activity metabolic tissues are at higher risk.
Cardiac:
- Myocardial infarction (acute and long term)
- Demand ischemia
- Reduced left ventricular function
- Dysrhythmia (prolonged QT)

Pulmonary:
- Inhalation injury
- Pulmonary edema
- Pneumonia (aspiration)
- Acute respiratory failure

Neurologic:
- Anoxic encephalopathy
- Vestibular and motor deficits
- Hippocampal atrophy
- Cognitive dysfunction
- Delayed posthypoxic leukoencephalopathy
- Diffuse brain atrophy
- Parkinsonism

Behavioral:
- Depression, anxiety
- Irritability, moodiness, and violence

Geriatric Considerations
Increased number of comorbid leading to possibility of complications and worse outcomes

CODES

ICD10
- T58.91XA Toxic effect of carb monx from unsp source, acc, init
- T58.8X1A Toxic effect of carb monx from oth source, accidental, init
- T58.01XA Toxic effect of carb monx from mtr veh exhaust, acc, init

CLINICAL PEARLS

- CO poisoning warrants a high index of suspicion, especially in patients exposed to fire; during the winter months, in young patients with chest pain; and when patients present as a group.
- Noninvasive CO oximeters are not reliable for the diagnosis of CO poisoning.
- If CO poisoning is suspected, remove individuals from the source and immediately administer 100% oxygen.
- Although not required, consider HBO₂ for the treatment of CO poisoning if it is available.
CARDIOMYOPATHY
Yousef Ahmed, MD ● Henry DeYoung, MD ● Derek Lodico, DO

BASICS

DESCRIPTION

- Cardiomyopathies are myocardial diseases which result in structural and functional heart abnormalities in the absence of coronary artery disease, congenital heart disease, valvular disease, or hypertension which could sufficiently explain the clinical myocardial dysfunction (1).
- Current classification scheme attempts to differentiate between myocardial diseases confined to the myocardium (primary) and those due to systemic disorders (secondary). Specific causes of myocardial dysfunction due to other cardiovascular disorders are considered a third, separate category (1).
- Classification of cardiomyopathies
  - Primary (mainly involves the myocardium)
    - Genetic
      - Hypertrophic cardiomyopathy (HCM)
      - Arrhythmogenic right ventricular cardiomyopathy/dysplasia (ARVC/D)
      - Left ventricular (LV) noncompaction (LVNC)
      - Glycogen storage (Danon type, PRKAG2)
      - Conduction defects
      - Mitochondrial myopathies
      - Ion channel disorders: long QT syndrome (LQTS), Brugada syndrome, short QT syndrome, and catecholaminergic polymorphic ventricular tachycardia (CPVT)
    - Mixed (genetic and nongenetic)
      - Dilated cardiomyopathy (DCM)
      - Restrictive (nonhypertrophied and nondilated)
    - Acquired
      - Myocarditis, stress cardiomyopathy, peripartum, tachycardia induced, infants of type 1 diabetic mothers
  - Secondary (multiorgan involvement; see list below)
    - Specific: ischemic, valvular, hypertensive, and congenital heart disease
- Patients with end-stage cardiomyopathy have stage D heart failure or severe symptoms at rest refractory to standard medical therapy.
- Systems affected: cardiovascular, renal, hepatic, and pulmonary

Pediatric Considerations
Progressive course and early diagnosis may alter disease course. Causes: DCM, HCM, RCM, LVNC in childhood, endocrine, uremic, nutritional

Pregnancy Considerations
Peripartum cardiomyopathy (PPCM) may occur in peripartum women well before and up to months after delivery.

EPIDEMIOLOGY
Predominant age: Ischemic cardiomyopathy is the most common etiology; predominantly in patients aged >50 years. Consider uncommon causes in young. In the young, HCM is the most common cause of sudden cardiac death and important underlying cause of heart failure disability.

**Incidence**
DCM: 5 to 8 new cases per 100,000 population annually

**Prevalence**
- DCM: roughly 1:2,500; third most common cause of heart failure and most common reason for heart transplantation
- HCM: at least 1:500 of the adult population
- RCM: more commonly seen in the tropics

**ETIOLOGY AND PATHOPHYSIOLOGY**
- HCM: hypertrophied, nondilated left ventricle without other systemic or cardiac disease which could produce wall thickening
- ARVC/D: involves the right ventricle with progressive loss of myocytes and fatty/fibrofatty tissue replacement; can be associated with myocarditis (adenovirus or enterovirus)
- LVNC: congenital cardiomyopathies with “spongy” appearance of the LV myocardium
- LQTS: most common ion channelopathy with prolonged ventricular repolarization and QTc
- DCM: Ventricular chamber enlargement and systolic dysfunction with normal LV wall thickness result in progressive heart failure and further complications; strong genetic component with infectious and toxic etiologies
- RCM: normal/decreased ventricular volume with restrictive physiology, biatrial enlargement, and impaired ventricular filling
- Myocarditis: acute or chronic inflammation of the myocardium produced by toxins, drugs, or infectious causes
- PPCM: a form of DCM with LV systolic dysfunction and heart failure of unknown etiology
- Stress cardiomyopathies: triggered by profound psychological stress resulting in acute but rapidly reversible LV systolic dysfunction
- Endocrine: diabetes mellitus, hyperthyroidism, hypothyroidism, hyperparathyroidism, pheochromocytoma, acromegaly
- Nutritional deficiencies: beriberi, pellagra, scurvy, selenium, carnitine, kwashiorkor
- Autoimmune/collagen: systemic lupus erythematosus, dermatomyositis, rheumatoid arthritis, scleroderma, polyarteritis nodosa
- Infectious causes
  - Viral (e.g., HIV, coxsackievirus, adenovirus)
  - Bacterial and mycobacterial (e.g., diphtheria, rheumatic fever)
  - Parasitic (e.g., toxoplasmosis, Trypanosoma cruzi)
- Infiltrative (2): amyloidosis, Gaucher disease, Hurler disease, Hunter disease, Fabry disease
- Storage: hemochromatosis, glycogen storage disease (type II, Pompe), Niemann-Pick disease
- Neuromuscular/neurologic: Duchenne and Emery-Dreifuss muscular dystrophies, Friedreich ataxia, myotonic dystrophy, neurofibromatosis, tuberous sclerosis
- Toxic: alcohol, drugs and chemotherapy (anthracyclines, cyclophosphamide, trastuzumab [Herceptin]), radiation, heavy metal, chemical agents
- Inflammatory (granulomatous): sarcoidosis
- Idiopathic
Endomyocardial: endomyocardial fibrosis, hypereosinophilic syndrome (Loeffler endocarditis)

**Genetics**
Autosomal dominant HCM is the most common form of primary genetic cardiomyopathy, which is commonly caused by many mutations that encode contractile proteins of the cardiac sarcomere. Genetic causes of DCM are less common, accounting for 1/3 cases, with mostly autosomal dominant inheritance. LVNC and ARVC are also inherited in an autosomal dominant fashion in addition to LQTS and other ion-channel disorders.

**RISK FACTORS**
- Hypertension
- Hyperlipidemia
- Obesity
- Coronary artery disease
- Diabetes mellitus
- Smoking
- Physical inactivity
- Excessive alcohol intake
- Dietary sodium
- Obstructive sleep apnea
- Chemotherapy

**GENERAL PREVENTION**
Reduce salt and water intake, and perform home blood pressure (BP) and daily weight measurements.

**DIAGNOSIS**

**HISTORY**
- Dyspnea at rest or with exertion
- Paroxysmal nocturnal dyspnea
- Orthopnea
- Postprandial dyspnea
- Right upper quadrant pain or bloating
- Fatigue
- Syncope
- Edema

**PHYSICAL EXAM**
- Tachypnea
- Cheyne-Stokes breathing
- Low pulse pressure
- Cool extremities
- Jugular venous distention
- Bibasilar rales
- Tachycardia
- Displaced point of maximal impulse (PMI)
- S₃ gallop
- Blowing systolic murmur
- Hepatosplenomegaly
- Ascites
- Edema

**DIFFERENTIAL DIAGNOSIS**
- Severe pulmonary disease
- Primary pulmonary hypertension
- Recurrent pulmonary embolism
- Constrictive pericarditis
- Some advanced forms of malignancy
- Anemia

**DIAGNOSTIC TESTS & INTERPRETATION**
- ECG: LV hypertrophy, interventricular conduction delay, atrial fibrillation, evidence of prior Q-wave infarction
- Hyponatremia
- Prerenal azotemia
- Anemia
- Mild elevation in troponin
- Elevated B-type natriuretic peptide (BNP) or pro-BNP
- Mild hyperbilirubinemia
- Elevated liver function tests
- Elevated uric acid

**Initial Tests (lab, imaging)**
- ECG
- Chest radiograph
  - Cardiomegaly
  - Increased vascular markings to the upper lobes
  - Pleural effusions may or may not be present.
- Echocardiography
  - In DCM, four-chamber enlargement and global hypokinesis are present.
  - In HCM, severe LV hypertrophy is present.
  - Segmental contraction abnormalities of the LV are indicative of previous localized myocardial infarction.
- Cardiac MRI
  - May be useful to characterize certain nonischemic cardiomyopathies
- Stress myocardial perfusion imaging (MPI)
  - Recommended in those with new-onset LV dysfunction or when ischemia is suspected

**Diagnostic Procedures/Other**
Cardiac catheterization
- Helpful to rule out ischemic heart disease
- Characterize hemodynamic severity
- Pulmonary artery catheters may be reasonable in patients with refractory heart failure to help guide management.
TREATMENT

See “Heart Failure, Chronic” for detailed treatment protocols.

GENERAL MEASURES

- Reduction of filling pressures
- Treatment of electrolyte disturbances

MEDICATION

First Line

- Systolic failure syndromes
  - Either an ACE inhibitor or an ARB is equally effective and should be considered in all patients; initiate at low doses and titrate as tolerated to target doses (3)[A].
  - Sacubitril/valsartan (Entresto), a combination drug containing a neprilysin inhibitor and valsartan (ARNI), was approved in 2015 for the treatment of systolic heart failure (ejection fraction [EF] <40%) as an alternative to an ACE/ARB (4)[A].
  - In patients who have been stable on an ACE or ARB, morbidity and mortality may be further reduced (all-cause mortality reduction approximately NNT 33 over 2 years treatment) by replacement with an ARNI (4)[A], with careful monitoring needed for hypotension and angioedema.
  - Loop diuretics
    o May need to be given IV initially and then orally as patient stabilizes
  - Furosemide, 40 to 120 mg/day or TID (3)[A]
  - β-Blockers
    o Use with caution in acutely decompensated or low-cardiac output states.
    o Initiate with low doses and titrate as tolerated.
  - Metoprolol succinate, 12.5 to 200 mg/day; carvedilol, 3.125 to 25 mg BID; or bisoprolol, 1.25 to 10 mg/day (3)[A]
  - Patients with New York Heart Association (NYHA) II to IV heart failure, EF <35%, on standard therapy: aldosterone antagonists: spironolactone or eplerenone (3)[A]
  - Digoxin, 0.125 to 0.250 mg/day for symptomatic patients on standard therapy (3)[B]
  - Combination hydralazine/isosorbide dinitrate is first-line treatment in African American patients with classes III and IV symptoms already on standard therapy and for all patients with reduced EF and symptoms incompletely responsive to ACE inhibitor and β-blocker (3) [A].
    o Contraindications
      • β-Blockers: low cardiac output, 2nd- or 3rd-degree heart block
      • Avoid use of diltiazem and verapamil in patients with systolic dysfunction.
      • Aldosterone antagonists: oliguria, anuria, renal dysfunction
      • Loop diuretics: hypokalemia, hypomagnesemia
      • ACE inhibitors: pregnancy, angioedema
      • ARNIs: patients currently on an ACE inhibitor or who have taken one in the past 36 hours, patients with a history of angioedema

- Precautions
  - In patients with chronic kidney disease, digoxin dosage should be ≤0.125 mg/day and drug levels followed carefully to avoid toxicity.
– Closely monitor electrolytes.
– ACE inhibitors and ARNIs: Initiate with care if BP is low.
– β-Blockers: Avoid in patients with evidence of poor tissue perfusion; they may further depress systolic function.
– Milrinone, dobutamine: long-term use associated with increased mortality

Medications to avoid
– NSAIDs
– Glitazones
– Cilostazol

Second Line
– Inotropic therapy (e.g., dobutamine or milrinone) for cardiogenic shock and support prior to surgery or cardiac transplantation (3)[B]
– Continuous inotrope infusion may be considered in stage D outpatients for symptom control in those who are not eligible for transplantation or mechanical circulatory support (3)[B].

ISSUES FOR REFERRAL
Management by a heart failure team improves outcomes and facilitates early transplant referral.

ADDITIONAL THERAPIES
– Prophylactic implantable cardioverter-defibrillator (ICD) should be considered for patients with a left ventricular ejection fraction (LVEF) <35% and mild to moderate symptoms (3)[A].
– Cardiac resynchronization therapy (CRT) is recommended and should be considered for patients in sinus rhythm with a QRS >150 ms, LVEF <35%, in functional class (FC) I to III, and ambulatory FC IV patients (3)[A].
– Patients with severe, refractory heart failure with no reasonable expectation of improvement should not be considered for an ICD. Palliative care is a reasonable option in such patients.
– Consideration of an LV assist device as “permanent” or destination therapy or cardiac transplantation is reasonable in selected stage D patients.

ONGOING CARE

DIET
Low fat, low salt, fluid restriction

PROGNOSIS
~20–40% of patients in NYHA FC IV die within 1 year. With a transplant, 1-year survival is as high as 94%.

COMPLICATIONS
Worsening congestive heart failure syncope, renal failure, arrhythmias, or sudden death

CODES

ICD10
- I42.9 Cardiomyopathy, unspecified
- I42.0 Dilated cardiomyopathy
- I42.5 Other restrictive cardiomyopathy

CLINICAL PEARLS
- Cardiomyopathy represents the end-stage of a large number of disease processes involving the heart muscle.
- Ischemic, hypertensive, postviral, familial, alcoholic, and incessant tachycardia-induced are the most common cardiomyopathy varieties seen in the United States.
- Core therapy for heart failure applies salt restriction, diuretics, ACE inhibitors, β-blockers, digoxin, and electrical treatments, such as cardiac resynchronization and implantable defibrillators, as appropriate.
CAROTID SINUS HYPERSENSITIVITY
Amal Shine, MD • Brock Kabat, MD • Hugh R. Peterson, MD, FACP

BASICS

DESCRIPTION
- The carotid sinus, located at the bifurcation of the internal and external carotid arteries, contains baroreceptors that are responsive to increases or decreases in arterial pressure. It plays a central role in blood pressure (BP) homeostasis.
- An endogenous increase in BP or external pressure applied to a carotid sinus causes an increase in the baroreceptor firing rate and activates vagal efferents and/or inhibits the sympathetic discharge to the heart and blood vessels, resulting in a slowing of the heart rate and/or drop in BP.
- In carotid sinus hypersensitivity (CSH), stimulation of one or both carotid sinuses causes an exaggerated baroreceptor response that can result in dizziness or syncope.
- CSH is defined as asystole for at least 3 seconds and/or a drop in systolic BP of at least 50 mm Hg during carotid sinus massage (CSM).
- CSH is generally divided into three subtypes, based on response to CSM:
  - Cardioinhibitory (70–75%): asystole for at least 3 seconds
  - Vasodepressor (5–10%): fall in systolic BP of at least 50 mm Hg
  - Mixed (20–25%): combination of the first 2 subtypes
- Carotid sinus syndrome (CSS) typically (but not consistently) refers to CSH with syncope and may be classified as:
  - Spontaneous CSS: syncope after accidental mechanical manipulation (trigger) of the carotid sinuses (e.g., shaving, tight collars, or tumors)
  - Induced CSS: syncope diagnosed by CSM although no mechanical trigger is found

EPIDEMIOLOGY
- Disease of elderly; virtually unknown in people aged <50 years
- More prevalent in males by ratio of 4:1
- Typical patient is an older man, usually with a history of coronary artery disease (CAD) and hypertension (HTN), with right CSH > left CSH

Prevalence
- In 2006 CSH was found in 39% of unselected adults >65 years of age using standard diagnostic criteria (1), and found to be comparable with 2019 review of prevalence data (2).
- CSH may be a cause of the symptoms in 30% of elderly patients with unexplained syncope

ETIOLOGY AND PATHOPHYSIOLOGY
- The exact mechanism of CSH remains unknown. Changes in any part of the reflex arc or the target organs may give rise to this condition, or it may be a part of a generalized autonomic disorder associated with autonomic dysregulation.
- Associated with resting sympathetic overactivity and increased baroreflex sensitivity
- Bradycardia and asystole seen in cardioinhibitory and mixed CSH subtypes appear to be mediated by vagal efferents, whereas vasodilatation and arterial hypotension in the vasodepressor and mixed subtypes are attributed to decrease sympathetic tone.
Symptomatic CSH has been shown to be associated with impaired cerebral autoregulation, and in asymptomatic CSH, it was found to be normal.

Atherosclerosis may diminish carotid sinus compliance, resulting in a reduction in afferent impulse traffic in the baroreflex pathway (3).

CSH is often idiopathic but can be caused by:
- Carotid body tumors
- Inflammatory and malignant lymph nodes in the neck
- Extensive scarring from prior neck surgery in the area of the carotid sinus
- Metastatic cancer

**RISK FACTORS**
- Male gender
- Advanced age
- CAD
- HTN
- DM

**COMMONLY ASSOCIATED CONDITIONS**
- Sick sinus syndrome
- Atrioventricular block
- CAD
- HTN
- Orthostatic hypotension
- Vasovagal syncope
- Alzheimer disease
- Parkinson disease

**DIAGNOSIS**

**HISTORY**
- Recurrent syncope: usually sudden, unexplained, of short duration, seemingly spontaneous, and with complete recovery, although fractures and other injuries may occur
- Unexplained falls: Evidence of a causal relationship is suggested between falls and the cardioinhibitory subgroup.
- Dizziness: Manifests as transient light-headedness or presyncope but not usually as true vertigo; associated more with vasodepressor and mixed subtypes
- Syncope may be associated with prodrome or retrograde amnesia.
- Causative or exacerbating factors
  - Any CSM-like maneuver such as shaving, wearing tight collars, or turning one’s head sharply
  - Neck tumors, extensive neck scarring secondary to radical dissection or radiation fibrosis, and neck trauma
  - Certain medications can potentiate symptoms associated with CSH:
    - Digoxin or β-blockers (especially with cardioinhibitory subtype)
    - Physostigmine, morphine, methacholine, increase vagal sensitivity and may predispose to cardioinhibitory subtype of CSH
PHYSICAL EXAM
Normal unless carotid baroreceptor is stimulated, then
- Bradycardia
- Hypotension
- Pallor
- Diaphoresis

DIFFERENTIAL DIAGNOSIS
- Neurocardiogenic syncope
- Postural hypotension
- Situational syncope
- Postural tachycardia syndrome (POTS)
- Primary autonomic insufficiency
- Hypovolemia
- Dysrhythmias
- Sick sinus syndrome
- Cerebrovascular insufficiency
- Other causes of syncope (e.g., metabolic, psychogenic)
- Electrocardiogram may demonstrate sinus pause(s) or atrial-ventricular block.
- Carotid duplex scan to rule out carotid stenosis in presence of a bruit (see the following section)

DIAGNOSTIC TESTS & INTERPRETATION
Diagnostic Procedures/Other
- CSM is indicated in patients >40 years of age with syncope of unknown etiology after a negative initial evaluation (4)[B].
- Commonly accepted technique for accurate diagnosis involves the following steps:
  - Patient in supine position for 5 minutes with continuous BP monitoring and ECG (on footplate-type tilt table for increased diagnostic accuracy); baseline BP and ECG are recorded.
  - For 5 to 10 seconds, apply firm longitudinal massage over the right carotid sinus (between the superior border of the thyroid and the angle of the mandible) at the site of maximal pulsation:
    - Note that light pressure over the carotid sinus will not reliably produce a hypersensitivity response.
    - Record symptoms, BP, and note ECG changes.
    - Discontinue if asystole ≥3 seconds
  - If initial test nondiagnostic, apply pressure to the left carotid sinus while the patient remains supine; if still nondiagnostic, repeat in 70-degree head-up tilt (first on the right then, if necessary, the left), allowing time for hemodynamic adjustment to the head-up position.
  - Evidence behind the testing strategy
  - Right side first: Up to 66% with CSH have positive response on the right; if a positive right response, no need to repeat test on the left side
  - 30% of CSM exams are found to be nondiagnostic in the supine position, positive predictive value increases from 77% to 96% with a specificity of 93% by performing CSM in the 70-degree position (5)
  - Absolute contraindications for CSM testing
- Carotid bruit present: must examine via carotid ultrasound with Doppler first:
  - No testing if >70% stenosis
  - Supine only testing if 50–70% stenosis
- Myocardial infarction, transient ischemic attack, or stroke within the past 3 months
- Relative contraindications to CSM testing
- History of ventricular tachycardia or ventricular fibrillation
- False-positive results with CSM are relatively common in the elderly. Care should be taken to exclude other causes of syncope.
- Neurologic and cardiovascular complications have been reported during CSM.
  - Cardiovascular complications (primarily arrhythmia) are extremely rare. Transient neurologic symptoms and signs occur in up to 0.9% of patients. Persistent neurologic deficits are extremely rare following CSM. Correctly performed CSM should be considered a safe, low-risk procedure (3)[C].

**Test Interpretation**

Standard positive response criteria (asystole ≥3 seconds and/or drop in systolic BP ≥50 mm Hg) is based on historical observations, although expert review of more recent data suggest these criteria may be too sensitive (6)[C].

- Specificity of the CSM technique increases if reproduction of a patient’s syncope is demonstrated during a test (4)[B].

**TREATMENT**

**GENERAL MEASURES**

- No treatment is required for asymptomatic individuals.
- High-dietary salt intake and increased fluid intake may be helpful to maintain intravascular volume in patients with vasodepressor subtype and absence of other cardiovascular disease.

**MEDICATION**

**First Line**

No single agent has demonstrated long-term effectiveness for treatment of recurrent and symptomatic CSH.

**Second Line**

- Fludrocortisone or midodrine may be used to improve orthostatic symptoms in patients with vasodepressor subtype (not approved by FDA for this indication). However, fludrocortisone causes sodium and water retention and should be used with caution in elderly patients with heart disease. An adverse effect with midodrine is that it increases mean ambulatory BP (3) [C].
- Atropine may be used in the acute setting in patients with cardioinhibitory subtype with bradycardia.
- Some evidence of benefit from sertraline and fluoxetine in patients unresponsive to pacemakers (3)[C]

**SURGERY/OTHER PROCEDURES**

- 2017 College of Cardiology/American Heart Association/Heart Rhythm Society (ACC/AHA/HRS) Guideline for the Evaluation and Management of Patients With Syncope
recommendations:
– Class IIa indication: Permanent cardiac pacing is reasonable in patients with carotid sinus syndrome that is cardioinhibitory or mixed.
– Class IIb indication: It may be reasonable to implant a dual-chamber pacemaker in patients with carotid sinus syndrome who require permanent pacing.

- Permanent pacing may reduce the frequency of symptoms but may not completely eliminate them.
- Surgery for patients with CSH secondary to mass effect from tumor burden
- Carotid sinus denervation by surgery or radiation therapy is no longer recommended because of the high rate of complications.

**ONGOING CARE**

**PATIENT EDUCATION**
- Avoid precipitating maneuvers (as described above) that place pressure on the neck, such as tight collars and neckties.
- With syncope, restrict driving or other potentially hazardous activities until the patient is cleared by the physician (4).
- Avoid precipitating medications like vasodilators and those temporally related to symptoms.
- Teach patient to assume supine position if prodromal symptoms or presyncope occurs.
- Explain diagnosis, provide reassurance, and explain risk of recurrence.

**PROGNOSIS**
- The presence of CSH has not been demonstrated to confer an independent mortality risk.
- Untreated CSS patients have a syncope recurrence rate as high as 62% within 4 years.
- Patients with cardioinhibitory CSH who received a pacemaker had a significant reduction in their mean number of falls, from 9.3 to 4.1 falls in a 1-year follow-up period (3).

**REFERENCES**
ADDITIONAL READING

SEE ALSO

Syncope

CODES

ICD10
G90.01 Carotid sinus syncope

CLINICAL PEARLS

- Consider CSH as a potential cause for syncope, dizziness, or unexplained falls, especially in the elderly.
- Diagnose CSH via CSM (using firm pressure for 5 to 10 seconds), producing asystole of at least 3 seconds and/or a drop in systolic BP of at least 50 mm Hg.
- Remember to auscultate for carotid artery bruit prior to considering CSM (see Contraindications under “Diagnostic Procedures”).
- Consider dual-chamber pacemaker in patients with recurrent syncope and cardioinhibitory or mixed CSH subtypes.
- The finding of CSH does not exclude other causes of syncope.
CAROTID STENOSIS
Evangelos Giakoumatos, MD, MSc • Naureen Bashir Rafiq, MBBS

**BASICS**
Carotid stenosis may be caused by atherosclerosis, intimal fibroplasia, vasculitis, adventitial cysts, or vascular tumors; atherosclerosis is the most common etiology.

**DESCRIPTION**
- Narrowing of the carotid artery lumen is typically due to atherosclerotic changes in the vessel wall. Atherosclerotic plaques are responsible for 90% of extracranial carotid lesions and up to 30% of all ischemic strokes.
- A “hemodynamically significant” carotid stenosis produces a drop in pressure or a reduction in flow. It corresponds approximately to a 60–99% diameter-reducing stenosis.
- Carotid lesions are classified by the following:
  - Symptom status
    - Asymptomatic: tend to be homogenous and stable
    - Symptomatic: tend to be heterogeneous and unstable; present with stroke or transient cerebral ischemic attack
  - Degree of stenosis
    - High grade: 80–99% stenosis
    - Moderate grade: 50–79% stenosis
    - Low grade: <50% stenosis

**EPIDEMIOLOGY**
More common in men and with increasing age (see “Risk Factors”)

**Incidence**
Unclear (Asymptomatic patients often go undiagnosed.)

**Prevalence**
- Moderate stenosis
  - Age <50 years: men 0.2%, women 0%
  - Age >80 years: men 7.5%, women 5%
- Severe stenosis
  - Age <50 years: men 0.1%, women 0%
  - Age >80 years: men 3.1%, women 0.9%

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Atherosclerosis begins during adolescence, consistently at the carotid bifurcation. The carotid bulb has unique blood flow dynamics. Hemodynamic disturbances cause endothelial injury and dysfunction. Plaque formation in vessel wall results and stenosis then ensues.
- Initial cause is not well understood, but certain risk factors are frequently present (see “Risk Factors”). Tensile stress on the vessel wall, turbulence, and arterial wall shear stress seem to be involved.

**Genetics**
• Increased incidence among family members
• Genetically linked factors
  – Diabetes mellitus (DM), race, hypertension (HTN), family history, obesity
  – In a recent single nucleotide polymorphism study, the following genes were strongly associated with worse carotid plaque: TNFSF4, PPARA, TLR4, ITGA2, and HABP2.

**RISK FACTORS**
• Nonmodifiable factors: advanced age (>65 years old), male sex, family history, coronary artery disease (CAD), peripheral artery disease, aortic aneurysmal disease, congenital arteriopathies
• Modifiable factors: smoking, diet, dyslipidemia, physical inactivity, obesity, HTN, DM
• Possible factors: Chlamydia pneumoniae and Cytomegalovirus

**GENERAL PREVENTION**
• Antihypertensive treatment to maintain blood pressure (BP) <140/90 mm Hg (Systolic BP of 150 mm Hg is target in elderly.)
• Smoking cessation to reduce the risk of atherosclerosis progression and stroke
• Lipid control: regression of carotid atherosclerotic lesions seen with statin therapy

**COMMONLY ASSOCIATED CONDITIONS**
• Transient ischemic attack (TIA)/stroke
• CAD/myocardial infarction (MI)
• Peripheral vascular disease (PVD)
• HTN
• DM
• Hyperlipidemia

**DIAGNOSIS**
Screening for carotid stenosis is not recommended. However, in the setting of symptoms suggestive of stroke or TIA, workup for this condition may be indicated.

**HISTORY**
• Identification of modifiable and nonmodifiable comorbidities (see “Risk Factors”)
• History of cerebral ischemic event
• Stroke, TIA, amaurosis fugax (monocular blindness), aphasia
• CAD/MI
• Peripheral arterial disease
• Review of systems, with focus on risk factors for
  – Cardiovascular disease
  – Stroke (HTN and arrhythmias)

**PHYSICAL EXAM**
• Lateralizing neurologic deficits: contralateral motor and/or sensory deficit
• Amaurosis fugax: ipsilateral transient visual obscuration from retinal ischemia
• Visual field defect
• Dysarthria, aphasia (in the case of dominant hemisphere involvement, usually left)
• Carotid bruit (low sensitivity and specificity)
DIFFERENTIAL DIAGNOSIS
- Aortic valve stenosis
- Aortic arch atherosclerosis
- Arrhythmia with cardiogenic embolization
- Migraine
- Brain tumor
- Metabolic disturbances
- Functional/psychological deficit
- Seizure

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Workup for suspected TIA/stroke may include the following:
- Complete blood count with differential
- Basic metabolic panel
- Erythrocyte sedimentation rate (if temporal arteritis a consideration)
- Glucose/hemoglobin A1c
- Fasting lipid profile
- Duplex ultrasonography is the recommended initial diagnostic test in asymptomatic patients with known or suspected carotid stenosis.
- Duplex ultrasound (US) identifies ≥50% stenosis, with 98% sensitivity and 88% specificity.

Follow-Up Tests & Special Considerations
- Proceed to imaging if there is suggestion of stenosis from history or physical exam.
- Other noninvasive imaging techniques can add detail to duplex results:
  - CT angiography
    - 88% sensitivity and 100% specificity
    - Requires IV contrast with risk for subsequent renal morbidity
  - MR angiography
    - 95% sensitivity and 90% specificity
    - Evaluates cerebral circulation (extracranial and intracranial) as well as aortic arch and common carotid artery
    - The presence of unstable plaque can be determined if the following characteristics are seen:
      - Presence of thin/ruptured fibrous cap
      - Presence of lipid-rich necrotic core
      - Tends to overestimate degree of stenosis

Diagnostic Procedures/Other
Cerebral angiography is the traditional gold standard for diagnosis:
- Delineates the anatomy pertaining to aortic arch and proximal vessels
- The procedure is invasive and has multiple risks:
  - Contrast-induced renal dysfunction (1–5% complication rate)
  - Thromboembolic-related complications (1–2.6% complication rate) and neurologic complications
  - Should be used only when other tests are not conclusive
Test Interpretation

- Stenosis consistently occurs at the carotid bifurcation, with plaque formation most often at the level of the proximal internal carotid artery:
  - Plaque is thickest at the carotid bifurcation.
  - Plaque occupies the intima and inner media and avoids outer media and adventitia.
- Plaque histology
  - Homogenous (stable) plaques seldom hemorrhage or ulcerate:
    - Fatty streak and fibrous tissue deposition
    - Diffuse intimal thickening
  - Heterogenous (unstable) plaques may hemorrhage or ulcerate:
    - Presence of lipid-laden macrophages, necrotic debris, cholesterol crystals
    - Ulcerated plaques
  - Soft and gelatinous clots with platelets, fibrin, and red and white blood cells

TREATMENT

Smoking cessation, BP control, antiplatelet medication, and statin medication are the primary treatments for both asymptomatic and symptomatic carotid stenosis.

GENERAL MEASURES

- Lifestyle modifications: dietary control and weight loss, exercise of 30 min/day at least 5 days/week
- Patients should be advised to quit smoking and offered smoking cessation intervention to reduce the risk of atherosclerotic progression and stroke.
- Control of HTN with antihypertensive agents to maintain BP <140/90 mm Hg; <150/90 mm Hg in the elderly. In carefully selected individuals, tighter blood pressure control might reduce cerebrovascular events, but this remains uncertain.

MEDICATION

- Antihypertensive treatment (<140/90 mm Hg), <150/90 mm Hg in the elderly
- Diet, smoking cessation, and exercise are useful adjuncts to therapy.
- Statin initiation is recommended; choose moderate- to high-intensity statin therapy for anti-inflammatory benefit.
- A comprehensive program that includes tight control of HTN with ACE inhibitor or angiotensin receptor blocker treatment reduces the risk in individuals with diabetes. Stroke prevention benefit of intensive glucose lowering therapy has not been established (1)[A].
- Aspirin: 75 to 325 mg/day
- If patient has sustained TIA or ischemic stroke, antiplatelet therapy with
  - Aspirin alone (75 to 325 mg/day), or
  - Clopidogrel alone (75 mg/day), or
  - Aspirin plus extended-release dipyridamole (25 and 200 mg BID, respectively)
  - A combination of clopidogrel plus aspirin is NOT recommended within 3 months post-TIA or CVA.

ISSUES FOR REFERRAL

- For acute symptomatic stroke, order imaging and contact neurology.
- For known carotid stenosis, some suggest duplex imaging every 6 months if stenosis is >50%
and patient is a surgical candidate.

**SURGERY/OTHER PROCEDURES**

- Symptomatic carotid stenosis (history of ischemia ipsilateral to stenosis)
  - Carotid endarterectomy (CEA) is of some benefit in 50–69% symptomatic stenosis, highly beneficial for those with 70–99% stenosis without near occlusion and has no benefit in people with carotid near-occlusion (2)[A].
  - CEA is recommended for patients with a life expectancy of at least 5 years. The anticipated rate of perioperative stroke or mortality must be <6% (3)[B].
  - Treatment with aspirin (81 to 325 mg/day) is recommended for all patients who are having CEA. Aspirin should be started prior to surgery and continued for at least 3 months postsurgery but may be continued indefinitely (3)[B].
  - Carotid artery stenting (CAS) provides similar long-term outcomes as CEA (4)[A]. Age should be considered when planning a carotid intervention.
    - CAS has an increased risk of adverse cerebrovascular events in the elderly compared to the young but similar mortality risk. CEA is associated with similar neurologic outcomes in the elderly and young, at the expense of increased mortality (5)[A].
    - CAS is suggested in selected patients with neck anatomy unfavorable for arterial surgery and those with comorbid conditions that greatly increase the risk of anesthesia and surgery.
    - Dual antiplatelet therapy with aspirin (81 to 325 mg/day) plus clopidogrel (75 mg/day) is recommended for 30 days post-CAS.

- Asymptomatic patients
  - As compared with CAS, CEA is the preferred option for the management of asymptomatic carotid stenosis if a surgical option is chosen. CAS has the potential for increased risks of periprocedural stroke and periprocedural death (6)[A].
  - The advantage of surgical compared with medical therapy has decreased with contemporary medical management. It is not possible to make an evidence-based recommendation for or against surgical therapy with current literature (1)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Any patient with presentation of acute symptomatic carotid stenosis should be hospitalized for further diagnostic workup and appropriate therapy.
- Rapid evaluation for symptoms compatible with TIA should be obtained in the emergency department (ED) or inpatient setting.
- Discharge criteria: 24 to 48 hours post-CEA, if ambulating, taking adequate PO intake, and neurologically intact

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Duplex at 2 to 6 weeks postoperatively
- Duplex every 6 to 12 months
- Reoperative CEA or CAS is reasonable, if there is rapidly progressive restenosis.
- Patients with any of the following: renal failure, heart failure, diabetes, and age >80 years have
a high readmission rate following CEA; thus, intensive medical therapy and rigorous follow-up is recommended.

**DIET**
Heart-healthy diet low in saturated fat, no trans fat

**PATIENT EDUCATION**
For patient education materials on this topic, consult the following:
- American Heart Association: [http://www.heart.org](http://www.heart.org)

**COMPLICATIONS**
- Untreated: TIA/stroke (risk of ipsilateral stroke approximately 1.68% per year)
- Postoperative (status post CEA)
  - Perioperative (within 30 days)
    - Stroke/death, cranial nerve injury, hemorrhage, hemodynamic instability, MI
  - Late (>30 days postop)
    - Recurrent stenosis, false aneurysm at surgical site

**REFERENCES**

**ADDITIONAL READING**
- Jonas DE, Feltner C, Amick HR, et al. Screening for asymptomatic carotid artery stenosis: a

SEE ALSO

Algorithms: Stroke; Transient Ischemic Attack and Transient Neurologic Defects

CODES

ICD10
- I65.29 Occlusion and stenosis of unspecified carotid artery
- I65.21 Occlusion and stenosis of right carotid artery
- I65.22 Occlusion and stenosis of left carotid artery

CLINICAL PEARLS

- Atherosclerosis is responsible for 90% of all cases of carotid artery stenosis.
- Duplex US is the best initial imaging modality.
- Antiplatelet therapy and aggressive treatment of vascular risk factors are the mainstays of medical therapy.
- Compared with CEA, CAS increases the risk of any stroke and decreases the risk of MI. For every 1,000 patients opting for stenting rather than endarterectomy, 19 more patients would have strokes and 10 fewer would have MIs.
CARPAL TUNNEL SYNDROME
Frances A. Tepolt, MD, CAQSM ● Rahul Kapur, MD

BASICS

DESCRIPTION
- Symptomatic compression neuropathy of the median nerve
- Increased pressure within the carpal tunnel leads to compression of the median nerve and characteristic motor-sensory findings.
- The dorsal aspect of the carpal tunnel is composed of the carpal bones. The transverse carpal ligament defines the palmar boundary.
  - The carpal tunnel contains nine flexor tendons and the median nerve.
- Symptoms most commonly affect the dominant hand; >50% of patients will experience bilateral symptoms.
- System(s) affected: musculoskeletal, nervous

ALERT
Increased incidence during pregnancy (up to 20–45%)

EPIDEMIOLOGY
- Predominant age: 40 to 60 years
- Predominant sex: female > male (3:1 to 10:1)

Incidence
- Two peaks: late 50s (women), late 70s (both genders)
- Incidence up to 276/100,000 has been reported.
- Incidence increases with age.

Prevalence
- 4% in women and 2% in men; 50 cases per 1,000 individuals per year in United States
- 14% in diabetics without neuropathy and 30% in patients with diabetic neuropathy
- Rising prevalence may be the result of increasing lifespan and increasing prevalence of diabetes.
- Most expensive upper extremity musculoskeletal disorder; >$2 billion per year
- Carpal tunnel release (CTR) is one of the most frequently performed hand/wrist procedures, with approximately 600,000 CTR procedures per year
- Median time lost by U.S. workers with carpal tunnel syndrome (CTS) = 28 days

ETIOLOGY AND PATHOPHYSIOLOGY
- Combination of mechanical trauma, inflammation, increased pressure, and ischemic injury to the median nerve within the carpal tunnel
- Acute CTS caused by rapid and sustained pressure in carpal tunnel, usually secondary to trauma, may require urgent surgical decompression.
- Distal radius fractures and volar lunate dislocations increase risk.
- Chronic CTS divided into four categories:
  - Idiopathic: combination of edema and fibrous hypertrophy without inflammation
- Anatomic: persistent median artery, ganglion cyst, infection, space-occupying lesion in carpal tunnel
- Systemic: associated with conditions such as obesity, diabetes, hypothyroidism, rheumatoid arthritis, amyloidosis, scleroderma, renal failure, and drug toxicity
- Exertional: repetitive use of hands and wrists, repeated palmar impact, use of vibratory tools.

Genetics
Unknown; however, a familial type has been reported.

RISK FACTORS
- Prolonged postures in extremes of wrist flexion and extension including activities such as gardening, cycling, or tennis; repetitive exposure to vibration (motorcycle riding)
  - There is insufficient evidence to implicate computer use in the development of CTS.
- Alterations of fluid balance: pregnancy, rheumatoid arthritis, obesity, renal failure, hypothyroidism, congestive heart failure
  - CTS is the most common neuropathy in patients with rheumatoid arthritis.
- Neuropathic factors: diabetes, alcoholism, vitamin deficiency, or exposure to toxins

GENERAL PREVENTION
There is no known prevention for CTS. It is recommended to take occasional (e.g., hourly) breaks when doing repetitive work involving hands or if prolonged occupational exposure to vibratory tools.

COMMONLY ASSOCIATED CONDITIONS
- Diabetes, obesity; pregnancy; hypothyroidism
- Osteoarthritis of small joints of hand and wrist
- Hyperparathyroidism, hypocalcemia

DIAGNOSIS

HISTORY
- Nocturnal pain, numbness, and tingling of the thumb, index, long, and radial portion of the ring fingers; patients may not localize and alternatively describe the entire hand as being affected.
- Hand weakness during tasks such as opening jars is often noted early in the disorder.
- Atypical presentation involves paresthesias in radial digits, with pain radiating proximally along median nerve to elbow and sometimes the shoulder.
- Symptoms characteristically are relieved by shaking or rubbing the hands.
- During waking hours, symptoms occur when driving, talking on the phone, and occasionally when using the hands for repetitive maneuvers.
- Presence of predisposing factors, such as diabetes, obesity, acromegaly, pregnancy, or occupational exposure

PHYSICAL EXAM
- Durkan compression test: Direct compression of median nerve at carpal tunnel for 30 seconds elicits symptoms (87% sensitivity; 90% specificity).
- Positive Phalen sign: Holding the wrist in fully flexed position for 60 seconds precipitates
paresthesias (68% sensitivity; 73% specificity).
- Positive Tinel sign: Tapping over the palmar surface of the wrist proximal to the carpal tunnel may produce an electric sensation along the distribution of the median nerve (50% sensitivity; 77% specificity).
- Loss of two-point discrimination
- Wasting of thenar musculature is a late sign, poorly associated with ruling out CTS.

DIFFERENTIAL DIAGNOSIS
- Cervical spondylosis (carpal tunnel may also occur with cervical spine disease; “double crush”)
- Generalized peripheral neuropathy
- Brachial plexopathy, in particular upper trunk
- Central nervous system disorders (multiple sclerosis, cerebral infarction)
- Thoracic outlet syndrome
- Pronator syndrome
- Anterior interosseous syndrome
- Musculoskeletal disorders of the wrist:
  - Trauma or distal radius fracture
  - Degenerative joint disease
  - Rheumatoid arthritis
  - Ganglion cyst
- Scleroderma

DIAGNOSTIC TESTS & INTERPRETATION
- No laboratory test is diagnostic.
  - Normal serum thyrotropin (thyroid-stimulating hormone [TSH]) and normal serum chemistries help exclude secondary conditions associated with CTS.
- Special tests
  - Electrodiagnostic studies
    - Sensitivity 85%; specificity 95%
    - Most useful with low pretest probability and suspicion of alternate peripheral neuropathy, radiculopathy, or “double-crush” phenomenon with compression at multiple locations
    - Nerve conduction studies compare latency and amplitude of median nerve signals across the carpal tunnel.
- The most sensitive indicator is median sensory distal latency, which is prolonged in CTS.
- Standard radiographs of the wrist evaluate bony anatomy and degenerative joint disease but are not necessary to diagnose CTS.
- Ultrasound—rapid, noninvasive, painless modality; sensitivity 82%; specificity 92%; hypoechoic median nerve cross-sectional area >10 mm
- Magnetic resonance imaging is of limited benefit.

TREATMENT

GENERAL MEASURES
- Strong evidence supports immobilization (brace/splint/orthosis) and the use of local steroid (methylprednisolone) injection in improving patient-reported outcomes.
Strong evidence indicates that surgical treatment of CTS results in better functional improvements at 1 year compared with nonoperative treatment.

A trial of nonoperative management is generally recommended for patients with mild to moderate CTS symptoms.

**MEDICATION**

**First Line**

Mainstay treatments for mild to moderate carpal tunnel syndrome include night splinting and local corticosteroid injection.

- Recent research has shown significantly improved outcomes with a single relatively low dose local corticosteroid injection (40 mg methylprednisolone acetate) compared to night splints at short-term (6-week) follow-up (1)[A].
  - Improvements in pain and function are maintained over 6 months following local corticosteroid injection, while improvements can be seen over the same time period with splinting, resulting in no significant difference between injection and splinting at 6-month follow-up (1)[A].

- A positive response to injection may signal a higher likelihood of benefit of surgery.
- Side effects of injection include reduction of collagen and proteoglycan synthesis, limiting tenocytes, and reducing mechanical strength of tendon, leading to further degeneration and risk for rupture.
- No evidence supports multiple trials of injection, thus surgery should be considered for those with refractory or recurrent symptoms.

**Second Line**

- Oral corticosteroids are less effective than local corticosteroid injection but more effective than placebo in the short term; long-term benefits of oral corticosteroid use have not been shown (2)[A].
  - The long-term risks of even a short course of steroids should be balanced with the limited potential benefit of symptom improvement.

- Although commonly used, nonsteroidal anti-inflammatory medications provide no significant improvement in symptoms compared to placebo (2)[A].
  - Contraindications: GI intolerance
  - Precautions: GI side effects of NSAIDs may preclude their use in selected patients.

- Myofascial massage therapy, ultrasound, extracorporeal shockwave therapy (ESWT), interferential current, iontophoresis, and continuous shortwave diathermy can help to reduce symptoms and improve function in the short and mid-term, however more research is needed to understand long-term effects and to investigate which treatment parameters for physical therapy and electrophysical modalities are most effective (3)[A].

**ISSUES FOR REFERRAL**

Preoperative electrodiagnostic studies are generally obtained prior to any surgical intervention.

**SURGERY/OTHER PROCEDURES**

- Completely dividing the transverse carpal ligament provides symptom relief in >95% of patients.
- Surgical decompression is an outpatient procedure performed under local or regional anesthesia.
Incisional healing generally takes 2 weeks; an additional 2 weeks may be required before using the affected hand for tasks requiring strength.

Complete resolution of numbness in 93.8% of patients with severe CTS by electromyogram at follow-up of 9.3 years ([4][B]).

The approach should be based on surgeon and patient preference.
- Endoscopic surgery results in a shorter recovery time compared to open surgery, although outcomes are similar after 6 months ([5][A]).
- Patients undergoing endoscopic release are at greater risk of nerve injury and lower risk of scar tenderness compared to open release ([5][A]).

COMPLEMENTARY & ALTERNATIVE MEDICINE
No trial data support the use of vitamin B_6 in the prevention or treatment of CTS.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Patients treated nonoperatively (splinting, injections) require follow-up over 4 to 12 weeks to ensure adequate progress.
- There is only limited, low-quality evidence to suggest that rehabilitation exercises such as wrist immobilization, ice therapy, and multimodal hand rehabilitation are beneficial.
- 7–20% of patients treated surgically may experience recurrence.

PATIENT EDUCATION

PROGNOSIS
- Patients with severe CTS may not recover completely after surgical release. Paresthesias and weakness may persist, but nighttime symptoms generally resolve.
- If untreated, more severe cases of CTS can lead to numbness and weakness in the hand, atrophy of the thenar muscles, and permanent loss of median nerve function.

COMPLICATIONS
- Postoperative infection (rare)
- Injury to the median nerve or its recurrent (motor) branch

REFERENCES

ADDITIONAL READING

SEE ALSO

- Arthritis, Rheumatoid (RA); Hypoparathyroidism; Lupus Erythematosus, Systemic (SLE); Scleroderma
- Algoritms: Carpal Tunnel Syndrome; Pain in Upper Extremity

CODES

ICD10
- G56.0 Carpal tunnel syndrome
- G56.01 Carpal tunnel syndrome, right upper limb
- G56.02 Carpal tunnel syndrome, left upper limb

CLINICAL PEARLS

- Paresthesias associated with CTS are characteristically confined to the thumb, index, long, and radial 1/2 of the ring fingers of the affected hand.
- Thenar atrophy is a late finding, indicating severe nerve damage.
- The Durkan (carpal compression) test is superior to Tinel sign (tapping on median nerve over carpal tunnel) and Phalen maneuver (holding wrists in flexion) for the clinical diagnosis of
CTS.
- Often the diagnosis is clinical; electrodiagnostic studies provide objective evidence of nerve compression and are sensitive and specific for diagnosis.
- Steroid injection and night splinting are mainstays of treatment for mild to moderate CTS.
- Surgical release of the carpal tunnel is >90% effective long-term.
BASICS

DESCRIPTION

- A cataract is any opacity or discoloration of the lens, localized or generalized; the term is usually reserved for changes that affect visual acuity (1,2).
- Etymology: from Latin catarractes, for “waterfall”; named after foamy appearance of opacity
- Leading cause of blindness worldwide, estimated 20 million people (1,2)
- Types include the following:
  - Age related: 90% of total
  - Metabolic (diabetes via accelerated sorbitol pathway, hypocalcemia, Wilson disease)
  - Congenital (1/250 newborns; 10–38% of childhood blindness)
  - Systemic disease associated (myotonic dystrophy, atopic dermatitis [AD])
  - Secondary to associated eye disease, so-called complicated (e.g., uveitis associated with juvenile rheumatoid arthritis or sarcoid, tumor such as melanoma or retinoblastoma)
  - Traumatic (e.g., heat, electric shock, radiation, concussion, perforating eye injuries, intraocular foreign body)
  - Toxic/nutritional (e.g., corticosteroids)
- Morphologic classification:
  - Nuclear: exaggeration of normal aging changes of central lens nucleus, often associated with myopia due to increased refractive index of lens (Some elderly patients consequently may be able to read again without spectacles, so-called second sight of the aged.)
  - Cortical: outer portion of lens; may involve anterior, posterior, or equatorial cortex; radial, spoke-like opacities
  - Subcapsular: Posterior subcapsular cataract has more profound effect on vision than nuclear or cortical cataract; patients particularly troubled under conditions of miosis; near vision frequently impaired more than distance vision

System(s) affected: nervous

Geriatric Considerations
Some degree of cataract formation is expected in all people >70 years of age.

Pediatric Considerations
See Congenital cataract; may present as leukocoria

Pregnancy Considerations
See Congenital cataract (i.e., medications, metabolic dysfunction, intrauterine infection, and malnutrition).

EPIDEMIOLOGY

Incidence
- ~48% of the 37 million cases of blindness worldwide result from cataracts (1,2).
- Leading cause of treatable blindness and vision loss in developing countries (1,2)
- Predominant age: depends on type of cataract
Predominant sex: male > female

**Prevalence**
- Cataract type and prevalence are highly variable based on population demographic.
- An estimated 50% of people 65 to 74 years of age and 70% of people >75 years of age have age-related cataract.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Age-related cataract:
  - Continual addition of layers of lens fibers throughout life creates hard, dehydrated lens nucleus that impairs vision (nuclear cataract).
  - Aging alters biochemical and osmotic balance required for lens clarity; outer lens layers hydrate and become opaque, adversely affecting vision.
- Congenital:
  - Usually unknown etiology
  - Drugs (corticosteroids in 1st trimester, sulfonamides)
  - Metabolic (diabetes in mother, galactosemia in fetus)
  - Intrauterine infection during 1st trimester (e.g., rubella, herpes, mumps)
  - Maternal malnutrition
- Other cataract types:
  - Common feature is a biochemical/osmotic imbalance that disrupts lens clarity.
  - Local changes in lens protein distribution lead to light scattering (lens opacity).

**Genetics**
- Congenital (e.g., chromosomal disorders [Down syndrome])
- Genetics of age-related cataract are not yet established but likely multifactorial contribution.

**RISK FACTORS**
- Aging
- Cigarette smoking
- Ultraviolet (UV) sunlight exposure
- Diabetes
- Prolonged high-dose steroids
- Positive family history
- Alcohol

**GENERAL PREVENTION**
- Use of UV protective glasses
- Avoidance of tobacco products
- Effective control of diabetes
- Care with high-dose, long-term steroid use (systemic therapy > inhaled treatment)
- Protective methods using pharmaceutical intervention (e.g., antioxidants, acetylsalicylic acid [ASA], hormone replacement therapy [HRT]) show no proven benefit to date.

**COMMONLY ASSOCIATED CONDITIONS**
- Diabetes (especially with poor glucose control)
- Myotonic dystrophy (90% of patients develop visually innocuous change in 3rd decade; becomes disabling in 5th decade)
• AD (10% of patients with severe AD develop cataracts in 2nd to 4th decades; often bilateral)
• Neurofibromatosis type 2
• Associated ocular disease or “secondary cataract” (e.g., chronic anterior uveitis, acute [or repetitive] angle-closure glaucoma or high myopia)
• Drug induced (e.g., steroids, chlorpromazine)
• Trauma

DIAGNOSIS

HISTORY
• Age-related cataract:
  – Decreased visual acuity, blurred vision, distortion, or “ghosting” of images (1,2)
  – Problems with visual acuity in any lighting condition
  – Falls or accidents; injuries (e.g., hip fracture)
• Congenital: often asymptomatic; leukocoria; parents notice child’s visual inattention or strabismus.
• Other types of cataract:
  – May also present with decreased visual acuity
  – Appropriate clinical history or signs to help with diagnosis

PHYSICAL EXAM
• Visual acuity assessment for all cataracts
• Age-related cataract: lens opacity on eye examination
• Congenital:
  – Lens opacity present at birth or within 3 months of birth
  – Leukocoria (white pupil), strabismus, nystagmus, signs of associated syndrome (as with Down or rubella syndrome)
  – Note: must always rule out ocular tumor; early diagnosis and treatment of retinoblastoma may be lifesaving.
• Other types of cataract: may present with decreased visual acuity associated with characteristic physical findings (e.g., metabolic, trauma)

DIFFERENTIAL DIAGNOSIS
• An opaque-appearing eye may be due to opacities of the cornea (e.g., scarring, edema, calcification), lens opacities, tumor, or retinal detachment. Biomicroscopic examination (slit lamp) or careful ophthalmoscopic exam should provide diagnosis.
• In the elderly, visual impairment is often due to multiple factors such as cataract and macular degeneration, both contributing to visual loss.
• Age-related cataract is significant if symptoms and ophthalmic exam support cataract as a major cause of vision impairment.
• Congenital lens opacity in the absence of other ocular pathology may cause severe amblyopia.
• Note: Cataract does not produce a relative afferent pupillary reaction defect. Abnormal pupillary reactions mandate further evaluation for other pathology.

DIAGNOSTIC TESTS & INTERPRETATION
• Visual quality assessment: Glare testing, contrast sensitivity is sometimes indicated.
• Retinal/macular function assessment: potential acuity meter testing
- Workup of underlying process

**Test Interpretation**
Consistent with lens changes found in the type of cataract; however, diagnosis is made by clinical examination.

**TREATMENT**
- Outpatient (usually)
- ~1.64 million cataract extractions in the United States yearly (3,4)

**GENERAL MEASURES**
Eye protection from UV light

**MEDICATION**
There are currently no medications to prevent or slow the progression of cataracts.

**ISSUES FOR REFERRAL**
If patient has cataract and symptoms do not seem to support recommended surgery, a second opinion by another ophthalmologist may be indicated.

**SURGERY/OTHER PROCEDURES**
- Age-related cataract:
  - Surgical removal is indicated if visual impairment–producing symptoms are distressing to the patient, interfering with lifestyle or occupation, or posing a risk for fall or injury (3,4) [A].
  - Because significant cataract may develop gradually, the patient may not be aware of how it has changed his or her lifestyle. Physician may note a significant cataract, and patient reports “no problems.” Thus, evaluation requires effective physician–patient exchange of information.
  - Preoperative evaluation: by the primary care physician:
    - Patients on anticoagulants may need to be temporarily discontinued 1 to 2 weeks before surgery if possible (but not always necessary, thus need to discuss with ophthalmologist).
    - Patients who have ever taken an α-blocker such as tamsulosin (Flomax) should alert their ophthalmologist (increased risk of intraoperative floppy iris syndrome [IFIS] even in patients who no longer use these drugs).
  - Anesthesia: usually regional injection or topical with sedation and monitoring of vital signs
  - Surgical technique: cataract extraction via phacoemulsification through small incisions created by blade or laser, followed by implantation of a prosthetic intraocular lens; lenses have power calculated based on size of the eye and curvature of cornea usually to correct for distance vision; surgery performed on one (usually worse) eye, with contralateral surgery after recovery and if deemed necessary; generally takes <1 hour depending on surgical technique
  - Postoperative care: usually protective eye shield as directed, topical antibiotic, NSAIDs, and steroid ophthalmic medications; keeping eye protected, avoid lifting or bending over for a few weeks.
- Congenital cataract:
– Treatment is surgical removal of cataract. Newborns may require surgery within days to reduce risk of severe amblyopia. Use of lens implants is controversial because the eyes are growing.
– Postoperative care: long-term patching program for good eye to combat amblyopia; refractive correction of operative eye, with multiple repeat examinations; challenging for physician and parents

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

● As cataract progresses, an ophthalmologist may change spectacle correction to maintain vision. When this is no longer successful and interferes with patient’s activities of daily living, surgery is indicated.
● Following surgery, spectacle correction may be required to maximize near and/or far visual acuity. Refraction is usually prescribed several weeks after surgery.

PATIENT EDUCATION

Medline Plus on cataracts at: https://www.nlm.nih.gov/medlineplus/cataract.html

PROGNOSIS

● Ocular prognosis is good after cataract removal if no prior or coexisting ocular disease: 94.3% of otherwise healthy eyes achieve best corrected visual acuity of 20/40 or better. Success rates are lower with comorbidities such as diabetes and glaucoma (5).
● In congenital cataracts, prognosis often is poorer because of the high risk of amblyopia.

COMPLICATIONS

● Vary widely from delay in visual recovery or protracted visual discomfort to blindness and loss of eye

   Nearly all reported complications occur rarely (<2% of eyes) except for posterior capsule opacification (14.7–42.7% of eyes, usually treated with Nd:YAG laser capsulotomy in office with a rate of 4–25.3%) (6)[B].
   Poor preoperative visual acuity is related to surgical complications.

REFERENCES

2009;35(7):1234–1238.

SEE ALSO
- Floppy Iris Syndrome
- Algorithm: Cataracts

CODES

ICD10
- H26.9 Unspecified cataract
- H25.9 Unspecified age-related cataract
- Q12.0 Congenital cataract

CLINICAL PEARLS
- Cataracts are the leading cause of blindness worldwide; 90% are age-related.
- Primary indication for cataract surgery is visual impairment leading to significant lifestyle changes for the patient.
- For congenital cataracts, must always rule out ocular tumor because early diagnosis and treatment of retinoblastoma may be lifesaving.
- Before prescribing an α-blocker for an older adult with hypertension or a prostate or urinary retention problem, consider whether the patient has cataracts (due to increased risk of IFIS).
CELIAC DISEASE
Lloyd A. Runser, MD, MPH, FAAFP ● Radoslava Djigrova

BASICS

DESCRIPTION
● An immune-mediated reaction to dietary gluten (found in wheat, barley, rye) primarily affecting the small intestine in genetically predisposed individuals. Affected individuals cannot tolerate gliadin (a component of gluten found in rye, barley, and wheat)
● Presentations
  – Typical
    o Diarrheal illness characterized by villous atrophy with symptoms of malabsorption (steatorrhea, weight loss, vitamin deficiencies, anemia); resolves with a gluten-free diet (GFD)
    o <50% of adults present with gastrointestinal (GI) symptoms.
  – Atypical
    o Minor GI symptoms, with a myriad of extraintestinal manifestations (e.g., anemia, liver function tests, dental enamel defects, neurologic symptoms, infertility)
  – Asymptomatic (silent) disease
    o Found when screening first-degree relatives
    o Positive laboratory tests and genetics, without signs/symptoms; normal histology on biopsy
● System(s) affected: GI
● Synonym(s): celiac sprue; gluten-sensitive enteropathy

EPIDEMIOLOGY

Incidence
● 1 to 13/100,000 worldwide (1)
● 6.5/100,000 in United States (2)
● Primarily affects those of Northern European ancestry
● Predominant sex: female > male (3:2)

Prevalence
● 0.7% in the United States; an estimated 3 million Americans have celiac disease (3).
● 8 to 204/100,000 worldwide (1)

ETIOLOGY AND PATHOPHYSIOLOGY
Sensitivity to gluten, specifically gliadin protein fraction. Tissue transglutaminase (tTG) modification of the gliadin protein leads to immunologic cross-reactivity, inflammation, and tissue damage (villous atrophy) with subsequent GI symptoms and malabsorption.

Genetics
Homogeneity for HLA-DQ2/DQ8 increases risk of celiac disease and enteropathy-associated T-cell lymphoma.

RISK FACTORS
First-degree relatives: 5–20% incidence (1)
Second-degree relatives

**Pediatric Considerations**
No other risk factors (e.g., grain processing, genetically modified organisms, hygiene and illness during childhood, breastfeeding, time of introduction of solid foods, pollution, tobacco use, and medication) explain why some susceptible individuals develop celiac, whereas others do not (4).

**COMMONLY ASSOCIATED CONDITIONS**
- Dermatitis herpetiformis (DH): 85% of patients with DH have celiac disease. All patients should follow GFD (1).
- Secondary lactase deficiency
- Osteopenia and osteoporosis
- Thyroid disease: Hashimoto thyroiditis
- Type 1 diabetes: 3–10% of patients with type 1 diabetes also have celiac disease (1).
- Symptomatic iron deficiency: 10–15% have celiac disease.
- Elevated aspartate aminotransferase and alanine aminotransferase (with no direct cause)
- Hyposplenism
- Irritable bowel syndrome (IBS)
- Restless leg syndrome
- Celiac disease is associated with increased risk for adenocarcinoma and lymphoma of the small bowel.
  - The risk of lymphoproliferative malignancies depends on small intestinal histopathology.
  - Little to no increased risk in latent celiac disease (seropositive but normal biopsy)
- Associated autoimmune conditions (type 1 diabetes, autoimmune thyroiditis, primary biliary cirrhosis, autoimmune hepatitis, psoriasis, Sjögren disease)
- Associated genetic conditions (Down syndrome, IgA deficiency, Turner syndrome, Williams syndrome)

**Pregnancy Considerations**
- Prevalence of celiac disease: 2.5 to 3.5 times higher in women with unexplained infertility
- Up to 19% of men with celiac disease have androgen resistance. Semen quality and likelihood of pregnancy increase with GFD.
- Higher rates of low birth weight, prematurity, spontaneous abortions, intrauterine growth restriction, and stillbirths

**Pediatric Considerations**
Children with celiac disease at higher risk for type 1 diabetes, Down syndrome, Turner syndrome, Williams syndrome, IgA deficiency, and autoimmune thyroid disease (5)[C]

**DIAGNOSIS**

**HISTORY**
- Diarrhea, cramping are the most common GI symptoms.
- Steatorrhea (fatty stools)
- Abdominal pain or distension
- Nausea, vomiting, flatulence
- Weight loss, weakness, fatigue
- Delayed puberty
- Iron deficiency anemia
- Recurrent aphthous stomatitis
- Dental enamel hyperplasia
- Muscle cramps
- Bone or joint pain
- Anxiety, depression
- Tingling numbness in hands, feet
- Migraines
- In children, malabsorption may manifest as failure to thrive, short stature, or chronic fatigue
- Anorexia
- Constipation or encopresis

**PHYSICAL EXAM**
Physical examination is often normal. Findings include:
- Orthostatic hypotension
- Peripheral edema
- Oropharynx: aphthous stomatitis, glossitis, cheilosis
- Skin: dermatitis herpetiformis (symmetric erythematous papules and blisters on elbows, knees, buttocks, and back), signs of anemia
- Abdomen: distention

**DIFFERENTIAL DIAGNOSIS**
- Gluten allergy–type II allergic reaction with signs of anaphylaxis
- Nonceliac gluten sensitivity—GI symptoms and/or systemic symptoms improved by GFD but without biomarkers characteristic of celiac disease
- Short bowel syndrome, small intestinal bacterial overgrowth
- Lactose intolerance; dyspepsia
- Gastroesophageal reflux disease (GERD)
- Pancreatic exocrine insufficiency
- Crohn disease; Whipple disease
- Tropical sprue; hypogammaglobulinemia
- Intestinal lymphoma; microscopic colitis
- Autoimmune enteropathy; HIV enteropathy
- Acute enteritis; radiation enteritis
- Eosinophilic gastroenteritis; giardiasis
- IBS

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Tissue biopsy is the gold standard for diagnosis.
- Do not base diagnosis solely on serology in adults. Patients with symptoms highly suggestive of celiac disease or those with positive serologies should undergo endoscopy for small bowel biopsy while on a gluten-containing diet.
- Biopsy and histologic examination of duodenal bulb during routine upper endoscopy increases
the diagnostic yield of celiac disease. Sampling of the duodenal bulb and the distal duodenum is recommended to improve histologic confirmation of celiac disease.

- IgA anti-tTG is the preferred serologic test in patients >2 years (1)[C].
- Total serum IgA to screen for IgA deficiency

**ALERT**
Positive IgA tTG has high sensitivity and specificity (sensitivity, 95–98%; specificity, 95%) if on normal (non–gluten-free) diet for at least 4 weeks.

- IgA-deficient patients have false-negative IgA anti-tTG antibodies.
- IgA deficiency is 10 to 15 times more prevalent in patients with celiac disease.
- The tTG antibody test is the preferred test (over the deamidated gliadin peptide [DGP] antibody).

**Follow-Up Tests & Special Considerations**

- If patient is IgA deficient OR if IgA anti-tTG are negative, follow up with anti-DGP IgA and IgG.
  - Sensitivity, 94%; specificity, 99% (~anti-tTG)
- Do not use HLA DQ serotyping for initial diagnosis. Consider if discrepant serology–histology results in patients unable to test on GFD and children with Down syndrome (1)[C].
- Consider bone mineral density testing at the time of diagnosis and after 1 year (if osteopenia/osteoporosis on initial testing) or 2 years (if normal initially and patient still symptomatic or nonadherent to diet).
- Younger age on diagnosis, less severe initial histologic damage, and male gender increase likelihood for achieving mucosal recovery.

**Pediatric Considerations**

- Test symptomatic pediatric patients with IgA and IgA anti-tTG antibodies.
- Periodic monitoring with IgA anti-tTG Ab can assess dietary adherence.
- Negative serology cannot rule out CD.
- Consider HLA for high-risk children with negative serology.
- Limit IgA antiendomysial antibodies to patients with illnesses that increase false-positive tTG Ab, such as type I diabetes or autoimmune liver disease.

**Diagnostic Procedures/Other**

- Endoscopy with a minimum of four biopsies of distal duodenum and two of duodenal bulb at time of initial evaluation correctly diagnose 95% of children (1)[C].
- Video capsule endoscopy is a promising alternative with a sensitivity and specificity of 80% and 95%; particularly helpful if antibody screening and clinical picture are consistent with celiac disease despite nondiagnostic duodenal biopsies

**Test Interpretation**

Small-bowel biopsy

- Villous atrophy, hyperplasia and lengthening of crypts, infiltration of plasma cells, and intraepithelial lymphocytosis in lamina propria
- Villous atrophy also caused by Crohn disease, radiation enteritis, giardia, and other food intolerances
TREATMENT

GENERAL MEASURES
- Gluten-free diet (GFD)—avoid wheat, barley, and rye.
  - Rice, corn, and nut flour are safe and palatable substitutes (1)[C].
  - Grains: uncontaminated oats, rice, corn, tapioca, quinoa, amaranth, sorghum
- Levels of IgA antigliadin normalize with gluten abstinence.
- Lifelong abstinence is required; immune response to gluten will recur with resumption of gluten intake.

MEDICATION

First Line
Usually no medications. GFD is primary treatment.

Second Line
- In refractory disease, consult with GI for consideration of choice, dosing, and duration of second-line agents:
  - Steroids (prednisone (1)[C] or budesonide (1)[B])
  - Azathioprine (used with caution; use may lead to lymphoma) (1)[C]
  - Cyclosporine
  - Infliximab
  - Cladribine
- Depending on disease severity, patients may develop nutritional deficiencies that require appropriate supplementation.

ISSUES FOR REFERRAL
- Additional nutritional support with qualified dietitian
- Refractory celiac disease
- Child with positive celiac serology

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Many alternative therapies are under development. Future treatment may include predigestion of gluten with peptidase, tight junction blockade, transglutaminase 2 or HLA DQ2/DQ8 blockers, and induction of immune tolerance (4).
- Patients with celiac disease are at increased risk for pneumococcal infection. Pneumococcal vaccination should be considered, especially for those between the ages of 15 and 64 years who may not have received vaccination.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Consultation with registered dietitian
- Screen for osteoporosis and treat accordingly.
- Follow-up with GI at 3 to 6 months for serology and 12 months for repeat biopsy if indicated

Patient Monitoring
Repeat esophagogastroduodenoscopy if no clinical response to GFD or relapse in symptoms (1)[C].
Follow anti-tTG IgA or deaminated antigliadin antibodies as a measure of response/compliance with diet (vs. antigliadin IgA or IgG).

**DIET**
- Remove gluten: wheat, rye, barley, and products with gluten additives (processed food/meat, medications, hygiene products).
- Dietary change is challenging (especially identifying sources of “hidden” gluten) and should be coordinated with a skilled registered dietitian.

**PATIENT EDUCATION**
- Discuss how to recognize gluten in various products.
- Highlight potential complications and outcomes of failing to follow a GFD.
- Support groups and self-education
  - National Celiac Association: [https://nationalceliac.org/](https://nationalceliac.org/)
  - Beyond Celiac: [https://www.beyondceliac.org/](https://www.beyondceliac.org/)

**PROGNOSIS**
- Good prognosis if adherent to GFD
- Patients should see improvement within 7 days of dietary modification.
- Symptoms usually resolve in 4 to 6 weeks.
- It is unknown whether strict dietary adherence decreases cancer risk.

**COMPLICATIONS**
- Malignancy: Untreated and refractory patients have increased cancer risk, but successful treatment decreases risk to population baseline (1)[C].
- Refractory disease (rare ~1–2% of all patients)
  - May respond to prednisone
  - May need total parenteral nutrition
- Osteoporosis
- Dehydration
- Electrolyte depletion

CODES

ICD10
K90.0 Celiac disease

CLINICAL PEARLS

- Screen for celiac disease in patients with nonspecific GI symptoms, presumed IBS, dermatitis herpetiformis, unexplained transaminitis, or unexplained iron deficiency anemia.
- Test total IgA levels along with IgA anti-tTG antibodies in patients >2 years of age. Positive serology is not definitive.
- Diagnostic testing must be completed while on a gluten-containing diet.
- Endoscopic biopsy with histologic examination of the intestinal mucosa is the gold standard for diagnosis.
- Standard of treatment is a gluten-free diet. Patient symptoms should improve in 7 days if fully compliant.
BASICS

Infection of the skin is a common global health burden with >650,000 admissions per year in the United States alone (1).

DESCRIPTION

- An acute bacterial infection of the dermis and subcutaneous (SC) tissue

- Types and locations:
  - Periorbital cellulitis: bacterial infection of the eyelid and surrounding tissues (anterior compartment)
  - Orbital cellulitis: infection of the eye posterior to the septum; sinusitis is most common risk factor.
  - Facial cellulitis: preceded by upper respiratory infection or otitis media
  - Buccal cellulitis: infection of cheek in children associated with bacteremia (common before Haemophilus influenzae type B vaccine)
  - Peritonsillar cellulitis: common in children; associated with fever, sore throat, and “hot potato” speech
  - Abdominal wall cellulitis: common in morbidly obese patients
  - Perianal cellulitis: sharply demarcated, bright, perianal erythema
  - Necrotizing cellulitis: gas-producing bacteria in the lower extremities; more common in diabetics

EPIDEMIOLOGY

- Predominant sex: male = female
- Seasonality increased hospitalizations for cellulitis in the summer with fewer in the winter months (2).

Incidence
200/100,000 patient/years

Prevalence
- The exact prevalence is uncertain because cellulitis is common and not reportable. It affects all age groups and all races; however, certain types of cellulitis/microorganisms occur in certain populations.
- In the United States, ~14.5 million annual cases of cellulitis account for $3.7 billion in ambulatory costs (1).
- Cellulitis accounts for ~1.4% of hospitalizations in the U.S. and is associated with $5.5 billion in yearly costs (3).

ETIOLOGY AND PATHOPHYSIOLOGY

Cellulitis is caused by bacterial penetration through a compromise in the epidermis, the protective barrier of the skin.
Microbiology
- β-Hemolytic streptococci (groups A, B, C, G, and F), Staphylococcus aureus, including methicillin-resistant S. aureus (MRSA), and gram-negative aerobic bacilli are most common.
- S. aureus seen in periorbital and orbital cellulitis and IV drug users
- Pseudomonas aeruginosa seen in diabetics and other immunocompromised patients
- H. influenza causes buccal cellulitis.
- Clostridia and non–spore-forming anaerobes: necrotizing cellulitis (crepitant/gangrenous)
- Streptococcus agalactiae: cellulitis following lymph node dissection
- Pasteurella multocida and Capnocytophaga canimorsus: cellulitis preceded by bites
- Streptococcus iniae: immunocompromised hosts
- Rare causes: Mycobacterium, fungal (mucormycosis, aspergillosis, syphilis)

Genetics
No genetic pattern

RISK FACTORS
- Disruption of skin barrier: trauma, infection, insect bites, injection drug use, body piercing
- Inflammation: eczema or radiation therapy
- Edema due to venous insufficiency; lymphatic obstruction due to surgery or congestive heart failure (CHF)
- Elderly, diabetes, hypertension, obesity
- Recurrent cellulitis:
  - Cellulitis recurrence score (predicts recurrence of lower extremity cellulitis based on presence of lymphedema, chronic venous insufficiency, peripheral vascular disease, and deep venous thrombosis) (4)[A]
  - Recurrent cellulitis is seen in immunocompromised patients (HIV/AIDS), steroids and TNF-α inhibitor therapy, diabetes, hypertension, cancer, peripheral arterial or venous diseases, chronic kidney disease, dialysis, IV or SC drug use (4).

GENERAL PREVENTION
- Good skin hygiene
- Support stockings to decrease edema
- Maintain tight glycemic control and proper foot care in diabetic patients.

COMMONLY ASSOCIATED CONDITIONS
Abscess

DIAGNOSIS
Primarily a clinical diagnosis

HISTORY
- Previous trauma, surgery, animal/human bites, dermatitis, and fungal infection are portals of entry for bacterial pathogens.
- Pain, itching, and/or burning
- Fever, chills, and malaise
PHYSICAL EXAM
- Assess vital signs for hemodynamic stability
- Localized pain and tenderness with erythema, induration, swelling, and warmth
- Regional lymphadenopathy
- Purulent drainage (from abscesses)
- Orbital cellulitis: proptosis, globe displacement, limitation of ocular movements, vision loss, diplopia
- Facial cellulitis: malaise, anorexia, vomiting, pruritus, burning, anterior neck swelling

DIFFERENTIAL DIAGNOSIS
Toxic shock syndrome, venous stasis dermatitis (commonly mistaken as cellulitis), bursitis, acute dermatitis or intertrigo, herpes zoster or herpetic whitlow, deep vein thrombosis or thrombophlebitis, acute gout or pseudogout, necrotizing fasciitis or myositis, gas gangrene, osteomyelitis, erythema chronicum migrans or malignancy, drug reaction, sunburn, or insect stings

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- If there are signs of systemic disease (fever, heart rate >100 bpm, or systolic blood pressure <90 mm Hg): blood cultures, creatine phosphokinase, C-reactive protein (CRP). Consider serum lactate levels.
- White blood cell has 84% specificity and 43% sensitivity; CRP has a sensitivity of 67% and specificity of 95% (pars plana vitrectomy 95% and negative predictive value 68%).
- Aspirates from point of maximum inflammation are more sensitive (45% positive culture) than aspirates from leading edge (5% positive culture).
- Blood cultures: pathogens isolated in <5% of patients. Blood cultures in children are more likely to show a contaminant than true positive.
- Swab open cellulitis wounds for culture.
- Plain radiographs, computed tomography, and magnetic resonance imaging (MRI) are useful if osteomyelitis, fracture, necrotizing fasciitis, retained foreign body.
- MRI and ultrasound are most useful for evaluation of potential underlying abscesses.
- Gallium-67 scintigraphy helps detect cellulitis superimposed on chronic limb lymphedema.
- Procalcitonin is not useful in diagnosing early cellulitis.

Diagnostic Procedures/Other
Consider lumbar puncture in children with H. influenzae type B or if meningeal signs and facial cellulitis.

TREATMENT

GENERAL MEASURES
- Immobilize/elevate involved limb to reduce swelling.
- Sterile saline dressings or cool aluminum acetate compresses for pain relief
- Edema: compression stocking, pneumatic pumps; diuretic therapy for CHF patients
- Mark the area of cellulitis to monitor progression.
- Tetanus immunization if needed, particularly if there is an open (traumatic) wound
MEDICATION

First Line
- Target treatment if known pathogen and/or with certain exposures (animal bites)
- Empiric antibiotic selection:
  - Nonpurulent cellulitis
    - With nonpurulent drainage, target treatment toward β-hemolytic streptococci and methicillin-sensitive S. aureus.
    - Outpatient: treatment duration of 5 to 10 days (6)[C]
      - Oral: for mild cellulitis
        - Cephalexin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 3 to 4 doses
        - Dicloxacillin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 4 doses
        - Clindamycin 300 to 450 mg PO q6–8h; children: 20 to 30 mg/kg/day in 4 doses
      - IV: for rapidly progressing cellulitis
        - Cefazolin 1 to 2 g IV q8h; children: 100 mg/kg/day IV in 2 to 4 divided doses
        - Oxacillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
        - Nafcillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
        - Clindamycin 600 to 900 mg IV q8h; children: 25 to 40 mg/kg/day IV in 3 to 4 doses
  - Purulent cellulitis (probable community-acquired methicillin-resistant S. aureus)
    - Culture purulent wounds and follow up in 48 hrs.
    - Incise and drain abscesses and start empiric antibiotic therapy. Modify based on culture results; tailor duration based on clinical response (7)[C]:
      - Oral
        - Clindamycin 300 to 450 mg PO; children: 40 mg/kg/day in 3 to 4 doses
        - Trimethoprim-sulfamethoxazole (TMP-SMX) 1 DS tab PO BID; children: dose based on TMP at 8 to 12 mg/kg/day divided in 2 doses
        - Doxycycline 100 mg PO BID; children >8 years of age: ≤45 kg: 4 mg/kg/day divided in 2 doses; >45 kg: 100 mg PO BID
        - Minocycline 200 mg PO once and then 100 mg PO BID; children >8 years old: 4 mg/kg PO once and then 4 mg/kg PO BID
        - Linezolid 600 mg PO BID; children <12 years: 10 mg/kg/dose (max 600 mg/dose) PO TID; ≥12 years: 600 mg PO BID
        - Tedizolid 200 mg PO once daily; children: Dosing is not established.
      - IV
        - Vancomycin 15 to 20 mg/kg/dose IV every 8 to 12 hours
        - Daptomycin 4 mg/kg/dose IV once daily; if bacteremia is present or suspected: 6 mg/kg IV once daily
        - Linezolid 600 mg IV BID
        - Tedizolid 200 mg IV once daily
        - Ceftaroline 600 mg IV q12h
        - Tigecycline 100 mg IV once, thereafter 50 mg IV q12h
  - Necrotizing cellulitis: requires broad-spectrum coverage to cover clostridial and anaerobic species: ampicillin-sulbactam 1.5 to 3.0 g q6–8h IV or piperacillin-tazobactam 3.37 g q6–8h IV plus ciprofloxacin 400 mg q12h IV plus clindamycin 600 to 900 mg q8h IV; have a low threshold for consultation, intensive care, and emergent surgical consultation
  - Freshwater exposure: penicillinase-resistant: penicillin plus gentamicin or fluoroquinolone; salt water exposure: doxycycline 200 mg IV in 2 divided doses
Bites: The combination of amoxicillin and clavulanic acid is recommended for human and dog bites. Ticarcillin and clavulanic acid or the combination of a 3rd-generation cephalosporin (i.e., ceftriaxone) plus metronidazole provides adequate parenteral therapy for animal or human bites. If allergic to penicillin, use fluoroquinolone plus metronidazole.

Facial cellulitis in adults: ceftriaxone IV

Diabetic foot infection:
- Mild/moderate: cephalexin or cephalexin plus doxycycline or TMP-SMX plus amoxicillin clavulanate
- Severe: ampicillin/sulbactam or imipenem/cilastatin or meropenem; alternative: combinations of targeting anaerobes as well as gram-positive and gram-negative aerobes

If severe infection, toxicity, immunocompromised patients, or worsening infection despite empirical therapy, admit for empiric antibiotic therapy covering MRSA.

Recurrent streptococcal cellulitis: penicillin 250 mg BID, or if penicillin-allergic, use erythromycin 250 mg BID

Dalbavancin, a 2nd-generation lipoglycopeptide antibiotic with MRSA coverage, can be used to treat cellulitis and be administered rarely as once a week (7)[C].

Pediatric Considerations
- Avoid doxycycline in children ≤8 years old and during pregnancy.
- The Melbourne ASSET tool is helpful in determining the need for IV antibiotics in pediatric populations (sensitivity 60%, specificity 93%) (8).

Second Line
Mild infection
- Penicillin allergy: erythromycin 500 mg PO q6h
- Cephalexin remains a cost-effective therapy for outpatient management of cellulitis at current estimated MRSA levels.

SURGERY/OTHER PROCEDURES
- Débridement for gas and purulent matter
- Intubation or tracheotomy may be needed for cellulitis of the head or neck.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Severe infection, suspicion of deeper or rapidly spreading infection, tissue necrosis, or severe pain
- Marked systemic toxicity or worsening symptoms that do not resolve after 24 to 48 hours of therapy
- Patients with underlying risk factors or severe comorbidities
- Patients not improved with initial outpatient management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Repeat relevant labs (blood culture, CBC, potentially lumbar puncture) if patient is toxic or not improving.
• Cutaneous inflammation may worsen in the first 24 hours due to release of bacterial antigens. Symptomatic improvement usually occurs in 24 to 48 hours, but visible improvement may take 72 hours.

**DIET**
Glucose control in diabetics

**PATIENT EDUCATION**
Good skin hygiene

**PROGNOSIS**
With adequate antibiotic treatment, prognosis is good.

- Low-dose penicillin prophylaxis in patients with recurrent cellulitis decreases recurrence (**9**)[B].
- Older age, higher body mass index, and diabetes mellitus are factors that have been shown to lower early response to antibiotics.

**COMPLICATIONS**
- Local abscess or bacteremia, sepsis
- Superinfection with gram-negative organisms
- Lymphangitis, especially if recurrent
- Thrombophlebitis or venous thrombosis
- Bacterial meningitis
- Gangrene

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- L03.032 Cellulitis of left toe
- L03.312 Cellulitis of back [any part except buttock]
- L03.211 Cellulitis of face

CLINICAL PEARLS

- S. aureus and group A Streptococcus are the most common organisms causing cellulitis.
- Consider MRSA if cellulitis does not respond to antibiotics within 48 hours or if purulence present.
- Rapid expansion of infected area with red/purple discoloration and severe pain may suggest necrotizing fasciitis, requiring urgent surgical evaluation.
- Venous stasis dermatitis often mimics cellulitis leading to improper use of antibiotics.
CELLULITIS, ORBITAL
Robert T. Carlisle, MD, MPH ⋅ Paul M. Allred, MD

BASICS
DESCRIPTION
- Acute, severe, vision-threatening infection of orbital contents posterior to the orbital septum.
- Preseptal (previously referred to as periorbital) cellulitis is anterior to the septum. Location determines the appropriate workup and treatment.
- Synonym(s): postseptal cellulitis

EPIDEMIOLOGY
- No difference in frequency between genders in adults. Higher incidence in boys in childhood.
- More common in children
- Orbital cellulitis is much less common than preseptal cellulitis (1)

Incidence
The incidence of orbital cellulitis has declined since introduction of routine Haemophilus influenzae type b (Hib) vaccination.

ETIOLOGY AND PATHOPHYSIOLOGY
- Sinusitis is classically associated with orbital cellulitis. Local skin conditions are typically associated with preseptal cellulitis.
- The ethmoid sinus is separated from the orbit by the lamina papyracea ("layer of paper"), a thin bony separation, and is often the source of contiguous spread of infection to the orbit. The ethmoid sinus is present at birth.
- The orbital septum is a connective tissue barrier that extends from the skull into the lid and separates the preseptal from the orbital space.
- Cellulitis in the closed bony orbit causes proptosis, globe displacement, orbital apex syndrome (mass effect on the cranial nerves), optic nerve compression, and vision loss.
- Cultures of surgical specimens in adults often grow multiple organisms. In over 1/3 of cases, no pathogen is recovered (2)[B]. Blood cultures typically do not grow an organism.
- Most common organisms (3)[C].(4)[C]:
  - Staphylococcus aureus, Streptococcus pneumoniae, Streptococcus anginosus
- Less common organisms:
  - Moraxella catarrhalis, H. influenzae, group A β-hemolytic Streptococcus, Pseudomonas aeruginosa, anaerobes, phycomycosis (mucormycosis), aspergillosis, Mycobacterium tuberculosis, Mycobacterium avium complex, trichinosis, Echinococcus
- Haemophilus is no longer the leading cause of orbital cellulitis (3)[B].(4)[B]. Methicillin-resistant Staphylococcus aureus (MRSA) is increasingly a clinical consideration.

Genetics
No known genetic predisposition

RISK FACTORS
- Sinusitis is present in 80–100% of cases (3)[C]. Pansinusitis is often observed in adults (1).
Orbital trauma, retained orbital FB, ophthalmic surgery, and/or history of sinus surgery (1)
Dental, periorbital, skin, or intracranial infection; acute dacryocystitis (inflammation of the lacrimal sac) and acute dacryoadenitis (inflammation of the lacrimal gland)
Immunosuppressed patients are at increased risk of adverse outcomes.

GENERAL PREVENTION
- Routine Hib vaccination
- Appropriate treatment of bacterial sinusitis
- Proper wound care and perioperative monitoring of orbital surgery and trauma
- Avoid trauma to the sinus and orbital regions.

COMMONLY ASSOCIATED CONDITIONS
- Sinusitis, especially pansinusitis in adults
- Trauma and intraorbital FB
- Preseptal cellulitis
- Adverse outcomes include orbital apex syndrome, vision loss, ophthalmoplegia, abscess, meningitis, or cavernous sinus thrombosis

DIAGNOSIS

HISTORY
- Complaints of acute onset red, swollen, tender eye or eyelid, and pain with eye movements
- History of surgery, trauma, sinus or upper respiratory infection, dental infection
- Malaise, fever, stiff neck, mental status changes
- Specific signs of orbital cellulitis include:
  - Proptosis, double vision, ophthalmoplegia, vision loss (or decreased field of vision), pain with eye movement, decreased color vision (differentiating green and red)

ALERT
- Differentiating orbital from preseptal cellulitis is the critical diagnostic step. Preseptal cellulitis can be identified by exam or following computed tomography (CT) scan.
- Both preseptal and orbital cellulitis present with a red, swollen painful eye or eyelid.
- Diplopia, ophthalmoplegia, painful extraocular movements, proptosis, vision loss, and fever suggest orbital involvement.
- Contrast CT is the imaging method of choice and must be done for suspicion of orbital cellulitis.
- Treat with immediate IV antibiotics, hospital admission, and ophthalmology referral.
- Monitor frequently for vision loss, cavernous sinus thrombosis, abscess, and meningitis.

PHYSICAL EXAM
Vital signs
- Assess visual acuity (with glasses if required).
- Lid exam and palpation of the orbit
- Pupillary reflex for afferent pupillary defect
- Extraocular movements; assess for pain with eye movement—if present, then concerning for orbital cellulitis.
- Red desaturation: Patient views red object with one eye and compares to the other; reduced red
color may indicate optic nerve involvement.

- Proptosis; pain with palpation
- Confrontation visual field testing

**DIFFERENTIAL DIAGNOSIS**

- Preseptal cellulitis
  - Eyelid erythema with or without conjunctival erythema, afebrile, no pain on eye movement, no diplopia, normal eye exam, vision intact
- Metastatic tumors and autoimmune inflammation may masquerade as orbital cellulitis in rare cases; usually present with painless, slow onset of symptoms
- Idiopathic orbital inflammatory disease (orbital pseudotumor) (3)[C]
  - Afebrile, normal white blood cells (WBCs); usually subacute, may have pain, responds to steroids after ruling out orbital cellulitis
- Orbital foreign body
- Arteriovenous fistula (carotid-cavernous fistula)
  - Spontaneous or due to trauma; bruit may be present; insidious, subacute onset
- Cavernous sinus thrombosis
  - Signs of orbital cellulitis with cranial nerves III, IV, V, and VI findings; often bilateral and acute
  - Severe illness
- Acute thyroid orbitopathy
  - Afebrile; possible signs of thyroid disease
  - Bilateral orbital involvement
- Orbital tumor
  - Rhabdomyosarcoma, acute lymphoblastic leukemia, or metastatic tumors
  - Unilateral
  - Slow onset
- Trauma, insect bite, ruptured dermoid cyst
- Clinical signs help distinguish preseptal from orbital cellulitis. Preseptal infection causes erythema, induration, and tenderness of the eyelid and/or periorbital tissues, and patients rarely show signs of systemic illness. Local skin trauma, lacerations, or bug bites can be seen. Extraocular movements and visual acuity are intact.
- Orbital cellulitis also presents with red, swollen, painful eye or eyelid. More specific symptoms include proptosis, conjunctival edema, ophthalmoplegia, painful eye movements, and decreased visual acuity.

**DIAGNOSTIC TESTS & INTERPRETATION**

- Complete blood count with differential, C-reactive protein, erythrocyte sedimentation rate. Inflammatory markers can be higher with orbital cellulitis versus preseptal.
- Swab cultures of eye secretions or nasopharyngeal aspirates are often contaminated by normal flora but may identify causative organism(s).
- Cultures from orbital and sinus abscesses at the time of surgery more often yield positive results but should be limited to cases where invasive procedures are indicated. Cultures from sinus aspirates and abscesses may grow multiple organisms.
- Blood cultures (usually negative) should be obtained prior to initiation of antibiotic therapy in ill-appearing or febrile patients.
Initial Tests (lab, imaging)
- CT scan of orbits and sinuses with axial and coronal views, with and without contrast, is imaging modality of choice (5)[C]. Ultrasound (US) and magnetic resonance imaging (MRI) are alternatives.
  - Thin section (2 mm) CT, coronal and axial views with bone windows to differentiate preseptal from orbital cellulitis, confirm extension into orbit, detect coexisting sinus disease, and identify orbital or subperiosteal abscesses that may require surgery.
  - Deviation of medial rectus indicates intraorbital involvement.
- MRI offers superior soft tissue resolution for identification of cavernous sinus thrombosis but is less effective for bone imaging.
- US is used to rule out orbital myositis, locate FBs or abscesses, and follow progression of drained abscess.

Follow-Up Tests & Special Considerations
- Frequent eye exam and vital signs (q4h)
- Identify associated conditions, such as meningitis or orbital abscess.

Diagnostic Procedures/Other
Consult ophthalmology for slit lamp and dilated funduscopic exam; to evaluate proptosis, color vision, automated visual field, and need for surgery.

TREATMENT
Admit patients with orbital cellulitis for monitoring and treatment with broad-spectrum IV antibiotics (3).

MEDICATION
- Empiric antibiotic therapy to cover pathogens associated with acute sinusitis (S. pneumoniae, H. influenzae, M. catarrhalis, Streptococcus pyogenes) as well as for S. aureus, S. anginosus, and anaerobes
- Modify IV antibiotic treatment when culture and sensitivity results are available. Duration of IV therapy is usually a week. Additional PO therapy depends on response.
- Consider treatment of MRSA for severe infection or based on local resistance patterns
- PO antibiotic therapy for 2 to 3 weeks or longer (3 to 6 weeks) is recommended for patients with severe sinusitis and bony destruction.

First Line
- Ampicillin /sulbactam (Unasyn) or ceftriaxone plus metronidazole or clindamycin if anaerobic infection is suspected (2)
  - Ampicillin /sulbactam: 3 g IV q6h for adult; 200 to 300 mg/kg/day divided q6h for children
  - Ceftriaxone: 1 to 2 g IV q12h for adults or 100 mg/kg/day divided BID in children with maximum 4 g/day
  - Clindamycin: 600 mg IV q8h for adults; 20 to 40 mg/kg/day IV q6–8h for children (6)
  - Metronidazole: 500 mg IV q8h for adult; 30 to 35 mg/kg/day divided q8h for children

ALERT
In severe orbital cellulitis, in suspected or proven MRSA infection, vancomycin remains the
parenteral drug of choice. Use in conjunction with agents to cover gram-negative bacteria.

- Vancomycin: 1 g IV q12h for adults; 40 mg/kg/day IV divided q8–12h, max daily dose 2 g for children (2)

**Second Line**

Any number of antibiotic regimens have been reported as successful. There is no definitive consensus for best choice (1).

**ISSUES FOR REFERRAL**

Always admit to the hospital and consult with ophthalmology. Consider consultation with ID and ear/nose/throat for orbital cellulitis; neurology/neurosurgery if intracranial spread is suspected

**ADDITIONAL THERAPIES**

- Steroid use is controversial (3)[C].
- PO steroids as an adjunct to IV antibiotics for orbital cellulitis may speed resolution of inflammation (7)[C].
- Nasal decongestants are often recommended
- Topical erythromycin or nonmedicated ophthalmic ointment protects the cornea from exposure in cases with severe proptosis.
- PO antibiotics for ≥2 weeks are traditionally recommended following IV treatment.
- Children may be treated with amoxicillin/clavulanate 20 to 40 mg/kg/day divided TID or in adults 250 to 500 mg TID.

**SURGERY/OTHER PROCEDURES**

- IV antibiotic therapy is the initial therapy. 80–90% of cases respond to medical therapy without surgery.
- Surgical intervention warranted for visual loss, complete ophthalmoplegia, well-defined large abscess (>10 mm) on presentation, or no clinical improvement after 24 to 48 hours of antibiotic therapy
- Trauma cases may need débridement or FB removal.
- Orbital abscess may need surgical drainage.
- Surgical drainage with 4 to 8 weeks of antibiotics is the treatment of choice for brain abscess.
- Surgical interventions may include external ethmoidectomy, endoscopic ethmoidectomy, uncinectomy, antrostomy, and subperiosteal drainage.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Patients with orbital cellulitis should be admitted for IV antibiotics and serial eye exams to evaluate progression of infection or involvement of optic nerve.

- Follow temperature, WBC, visual acuity, pupillary reflex, ocular motility, and proptosis.
- Repeat CT scan or surgical intervention may be required for worsening orbital cellulitis cases.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Serial visual acuity testing and slit lamp exams
ALERT
Bedside exam q4h is indicated, as complications can develop rapidly.

PATIENT EDUCATION
- Maintain proper hand washing and good skin hygiene.
- Avoid skin or lid trauma.

PROGNOSIS
Historically, blindness occurred in 20% and death in 17% of cases before antibiotics. Vision loss occurs in 3–11% of cases (1).

COMPLICATIONS
- Vision loss, central nervous system (CNS) involvement, and death
- Permanent vision loss
  - Corneal exposure
  - Optic neuritis
  - Endophthalmitis
  - Septic uveitis or retinitis
  - Exudative retinal detachment
  - Retinal artery or vein occlusions
  - Globe rupture
  - Orbital compartment syndrome
- CNS complications
  - Intracranial abscess, meningitis, cavernous sinus thrombosis (4)[B]

REFERENCES

CODES
ICD10
- H05.019 Cellulitis of unspecified orbit
- H05.011 Cellulitis of right orbit
- H05.012 Cellulitis of left orbit

**CLINICAL PEARLS**

- Most cases of orbital cellulitis arise from sinusitis.
- CT of orbits and sinuses with axial and coronal views with and without contrast is diagnostic modality of choice.
- Patients with orbital cellulitis must be admitted for visual monitoring and IV antibiotic therapy.
- Older age (>10 years) and diplopia predict need for surgical intervention in children.
- Ophthalmoplegia, mental status changes, contralateral cranial nerve palsy, or bilateral orbital cellulitis raise suspicion for intracranial involvement.
CELLULITIS, PERIORBITAL
Fozia Akhtar Ali, MD

BASICS

DESCRIPTION
- An acute bacterial infection of the skin and subcutaneous tissue anterior to the orbital septum; does not involve the orbital structures (globe, fat, and ocular muscles)
- Synonym(s): preseptal cellulitis

ALERT
It is essential to distinguish periorbital cellulitis from orbital cellulitis. Orbital cellulitis is a potentially life-threatening condition. Orbital cellulitis is posterior to the orbital septum; symptoms include restricted eye movement, pain with eye movement, proptosis, and vision changes.

EPIDEMIOLOGY
- Occurs more commonly in children; mean age 21 months
- 3 times more common than orbital cellulitis (1)[C]

Incidence
Increased incidence in the winter months (due to increased cases of sinusitis) (1)[C]

ETIOLOGY AND PATHOPHYSIOLOGY
- The anatomy of the eyelid distinguishes periorbital (preseptal) from orbital cellulitis:
  - A connective tissue sheet (orbital septum) extends from the orbital bones to the margins of the upper and lower eyelids; it acts as a barrier to infection of deeper orbital structures.
  - Infection of tissues anterior to the orbital septum is periorbital (preseptal) cellulitis.
  - Infection deep to the orbital septum is orbital (postseptal) cellulitis.
- Periorbital cellulitis typically arises from a contiguous infection of soft tissues of the face.
  - Sinusitis (via lamina papyracea) extension
  - Local trauma; insect or animal bites
  - Foreign bodies
  - Dental abscess extension
  - Hematogenous seeding
- Common organisms (1)[C]
  - Staphylococcus aureus, typically MSSA (MRSA is increasing.)
  - Staphylococcus epidermidis
  - Streptococcus pyogenes
- Atypical organisms
  - Acinetobacter sp.; Nocardia brasiliensis
  - Bacillus anthracis; Pseudomonas aeruginosa
  - Neisseria gonorrhoeae; Proteus sp.
  - Pasteurella multocida; Mycobacterium tuberculosis; Trichophyton sp. (ringworm)
- Since vaccine introduction, the incidence of Haemophilus influenzae disease has decrease (should still be suspected in unimmunized or partially immunized patients).
Genetics
No known genetic predisposition

RISK FACTORS
- Contiguous spread from upper respiratory infection
- Acute sinusitis
- Conjunctivitis
- Blepharitis
- Dental infection
- Local skin trauma/puncture wound
- Insect bite
- Bacteremia

GENERAL PREVENTION
- Avoid trauma around the eyes.
- Avoid swimming in fresh or salt water with facial skin abrasions.
- Routine vaccination: particularly H. influenzae type B and Streptococcus pneumoniae

DIAGNOSIS

HISTORY
- Induration, erythema, warmth, and/or tenderness of periorbital soft tissue, usually with normal vision and normal eye movements
- Chemosis (conjunctival swelling), proptosis; pain with extraocular eye movements can occur in severe cases of periorbital cellulitis and are concerning for orbital cellulitis.
- Fever (not always present)

ALERT
Pain with eye movement, fever, and conjunctival swelling raise the suspicion for orbital cellulitis.

PHYSICAL EXAM
- Vital signs and general appearance (Patients with orbital cellulitis often appear systemically ill.)
- Inspect eyes and surrounding structures—lids, lashes, conjunctiva, and skin.
- Erythema, swelling, and tenderness of lids without orbital congestion
  - Violaceous discoloration of eyelid is more commonly associated with H. influenzae.
- Evaluate for skin break down.
- Look for vesicles to rule out herpetic infection.
- Inspect nasal vaults and palpate sinuses for signs of acute sinusitis.
- Examine oral cavity for dental abscesses.
- Test ocular motility and visual acuity.

DIFFERENTIAL DIAGNOSIS
- Orbital cellulitis
  - Orbital cellulitis may have the same signs and symptoms as periorbital cellulitis, with fever, proptosis, chemosis, ophthalmoplegia, decreased visual acuity, pain with ocular movement.
- Abscess
- Dacryocystitis
- Hordeolum (stye)
- Allergic inflammation
- Orbital or periorbital trauma
- Idiopathic inflammation from orbital pseudotumor
- Orbital myositis
- Rapidly progressive tumors
  - Rhabdomyosarcoma
  - Retinoblastoma
  - Lymphoma
- Leukemia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC with differential
- Blood cultures (low yield) \(^{(2)}\)[C]
- Wound culture of purulent drainage (if present)
- Imaging is indicated if there is suspicion for orbital cellulitis (marked eyelid swelling, fever, and leukocytosis or failure to improve on appropriate antibiotics within 24 to 48 hours).
- CT to evaluate the extent of infection and detect orbital inflammation or abscess:
  - CT with contrast, thin sections (2 mm); coronal and axial views with bone windows
  - The classic sign of orbital cellulitis on CT scan is bulging of the medial rectus.

**Follow-Up Tests & Special Considerations**
- Children with periorbital or orbital cellulitis often have underlying sinusitis.
- If a child is febrile, <15 months old, and appears toxic, admit for blood cultures, antibiotic therapy, and consider lumbar puncture.

**TREATMENT**

**MEDICATION**
- Treat periorbital cellulitis with oral antibiotics and ensure close follow-up.
- Empiric antibiotic treatment should cover the most likely organisms (Staphylococcus and Streptococcus).
- Observe local prevalence of MRSA to determine need for coverage.
- No evidence that IV antibiotics are more effective than PO in reducing recovery time or preventing secondary complications in simple periorbital cellulitis \(^{(1)}\)[C]
- No evidence for steroid use

**First Line**
- Uncomplicated posttraumatic periorbital cellulitis
  - Usually due to skin flora, including Staphylococcus and Streptococcus
  - Cephalexin 500 mg PO q6h or dicloxacillin 500 mg PO q6h
  - Clindamycin 300 mg PO TID, doxycycline 100 mg PO BID, or trimethoprim-sulfamethoxazole (TMP-SMX) 1 to 2 DS tablets PO q12h if MRSA is suspected
- Extension from sinusitis
  - Amoxicillin-clavulanate 875 mg PO BID
  - 3rd-generation cephalosporin (e.g., cefdinir 300 mg PO BID)
- Dental abscess
  - Amoxicillin-clavulanate 875 mg PO BID or clindamycin 300 mg PO TID
- Bacteremic cellulitis
  - May be associated with meningitis
  - Ceftriaxone 1 g IV q24h plus vancomycin 15 mg/kg/dose IV q8–12h or clindamycin 600 to 900 mg IV q8h to cover MRSA
  - Duration of therapy: A 10- to 14-day course is usually sufficient. Follow patients treated with oral antibiotics for presumed peri-orbital cellulitis closely (daily follow-up until improvement occurs) for response to antibiotics and possible progression to orbital cellulitis. If symptoms do not improve within 24 hours, reevaluate for IV antibiotic therapy.

ISSUES FOR REFERRAL
Consult ENT and ophthalmology if there is concern for orbital cellulitis or if patients do not respond quickly to first-line treatment (3).

SURGERY/OTHER PROCEDURES
- Usually not indicated in uncomplicated cases
- If there is an abscess or potential compromise of critical structures, orbital surgery is indicated.
- Diplopia is the strongest clinical predictor for surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- If the patient is stable and there are no systemic signs of toxicity, mild cases in adults and children >1 year of age can be safely managed on an outpatient basis.
- Consider hospitalization and IV antibiotics:
  - If patient appears systemically ill
  - Children <1 year of age (3,4)[C]
  - Patients not immunized against S. pneumoniae or H. influenzae
  - If patients do not improve or deteriorate within 24 hours of oral antibiotics
  - High suspicion for orbital cellulitis (eyelid swelling with reduced vision, diplopia, abnormal light reflexes, or proptosis)
- No strict guidelines indicate when to switch from parenteral to PO therapy. In general, a switch from IV to oral antibiotics is reasonable once eyelid edema and erythema have significantly improved.
- A 10- to 14-day course of antibiotics is indicated.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Follow for signs of orbital involvement, including decreased visual acuity or painful/limited ocular motility.

PATIENT EDUCATION
● Maintain good skin hygiene.
● Avoid skin trauma.
● Report early skin changes (swelling, redness, and pain) if recurrent after a course of therapy.

PROGNOSIS
● With timely treatment, patients do well.
● Recurrent periorbital cellulitis occurs with ≥3 periorbital infections in 1 year with at least 1 month of in between episodes; must be differentiated from treatment failure due to antibiotic resistance (1)[C]

COMPLICATIONS
● Orbital cellulitis; orbital abscess formation
● Scarring
● Vision loss
● Cavernous sinus thrombosis
● Osteomyelitis

REFERENCES

ADDITIONAL READING

CODES
ICD10
L03.211 Cellulitis of face

CLINICAL PEARLS
● Periorbital (preseptal) and orbital (postseptal) cellulitis occur most commonly in children.
● CT scan of sinuses and orbits can differentiate periorbital cellulitis from orbital cellulitis.
● Orbital cellulitis typically has fever, pain with eye movement, diplopia, and/or proptosis.
● Prompt imaging is necessary if there is a concern for orbital cellulitis.
BASICS

DESCRIPTION
Cerebral palsy (CP) is a group of clinical syndromes characterized by motor and postural dysfunction due to permanent and nonprogressive disruptions in the developing brain. Motor impairment resulting in activity limitation is necessary for this diagnosis. CP is classified by the nature of the movement disorder and its functional severity. Individuals with this disorder are affected with secondary musculoskeletal and neurologic problems (intellectual, sensory, speech and language impairment, and seizures).

EPIDEMIOLOGY

Incidence
- Overall, 1.5 to 2.5/1,000 live births
- Incidence increases as gestational age (GA) at birth decreases:
  - 146/1,000 for GA of 22 to 27 weeks
  - 62/1,000 for GA of 28 to 31 weeks
  - 7/1,000 for GA of 32 to 36 weeks
  - 1/1,000 for GA of 37+ weeks

Prevalence
3 to 4/1,000 of the population

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial; CP results from static injury or lesions in the developing brain, occurring prenatally, perinatally, or postnatally.
- Neuropathology linked to GA at time of brain insult
- Cytokines, free radicals, and inflammatory response are likely contributing factors.
- Etiology is most likely multifactorial and depends on timing of brain insult: prenatally, perinatally, or postnatally (see “Risk Factors”).
- Spastic CP is most common, usually related to premature birth, with either periventricular leukomalacia or germinal matrix hemorrhage.
- Dystonic or athetotic CP, often resulting from kernicterus, is now rare due to improved management of hyperbilirubinemia.

Genetics
There are reports of associations between CP and polymorphisms of certain genes: thrombophilic, cytokines, and apolipoprotein E.

RISK FACTORS

- Prenatal: congenital anomalies, multiple gestation, in utero stroke, intrauterine infection (cytomegalovirus [CMV], varicella), intrauterine growth retardation (IUGR), clinical and histologic chorioamnionitis, antepartum bleeding, maternal factors (cognitive impairment, seizure disorders, hyperthyroidism), abnormal fetal position (e.g., breech)
Perinatal: preterm birth, low-birth weight, periventricular leukomalacia, perinatal hypoxia/asphyxia, intracranial hemorrhage/intraventricular hemorrhage, neonatal seizure or stroke, hyperbilirubinemia
Postnatal: traumatic brain injury or stroke, sepsis, meningitis, encephalitis, asphyxia, and progressive hydrocephalus

GENERAL PREVENTION
- Treating mothers with magnesium sulfate during preterm delivery is neuroprotective for fetus and may reduce the risk of CP. Effect on term fetus is unknown (1)[B].
- Improved management of hyperbilirubinemia with decrease in kernicterus has greatly reduced dyskinetic CP.
- Prevention or reduction of chorioamnionitis and premature births

COMMONLY ASSOCIATED CONDITIONS
- Seizure disorder (22–40%)
- Intellectual impairment (23–44%)
- Behavioral problems
- Speech and language impairment (42–81%)
  - May have an impact on expressive and/or receptive language
  - May be nonverbal
- Sensory impairments
  - Hearing deficits
  - Visual (62–71%): poor visual acuity, strabismus (50%), or hemianopsia
- Feeding impairment, swallowing dysfunction, and aspiration: when severe, may require gastrostomy feedings
- Poor dentition, excessive drooling
- GI conditions: constipation (59%), vomiting (22%), gastroesophageal reflux
- Decreased linear growth and weight abnormalities (under- and overweight)
- Osteopenia
- Bowel and bladder incontinence
- Orthopedic: contractures, hip subluxation/dislocation, scoliosis (60%)

DIAGNOSIS
- A clinical diagnosis including
  - Delayed motor milestones
  - Abnormal tone
  - Abnormal neurologic exam suggesting a cerebral etiology for motor dysfunction
  - Absence of regression (not losing function)
  - Absence of underlying syndromes or alternative explanation for etiology
- Although the pathologic lesion is static, clinical presentation may change as the infant grows and develops.
- Accurate early diagnosis remains difficult. Neurologic abnormalities observed in the first 1 to 2 years of life may resolve; be cautious of diagnosing CP before age 2 years.
- Serial exams are often required for a definitive diagnosis.

HISTORY
- Presentation: concerns over movements or delayed motor development
- Ask about
  - Prenatal, perinatal, and postnatal risk factors
  - Neurobehavioral signs
    - Poor feeding/frequent vomiting
    - Irritability
  - Timing of motor milestones: Delay in milestones is not sensitive or specific until after 6 months of age.
  - Abnormal spontaneous general movements
  - Asymmetry of movements such as early hand preference
- Regression of motor skills does not occur with CP.

**PHYSICAL EXAM**
- Assess for more than one type of neurologic impairment:
  - Spasticity: increased tone/reflexes/clonus
  - Dyskinesia: abnormal movements
  - Hypotonia: decreased tone
  - Ataxia: abnormal balance/coordination
- Areas of exam
  - Tone: may be increased or decreased
  - Trunk and head control: often poor but may be advanced due to high tone
  - Reduced strength and motor control
  - Persistence of primitive reflexes
  - Asymmetry of movement or reflexes
  - Decreased joint range of motion and contractures
  - Brisk deep tendon reflexes
  - Clonus
  - Delayed motor milestones: serial exams most effective
  - Gait abnormalities: scissoring, toe walking
- CP is classified by the following:
  - Muscle tone or movement disorder
    - Spasticity
      - Unilateral: hemiplegic
      - Bilateral: diplegic (lower extremity [LE] > upper extremity [UE] involvement) or quadriplegic (UE ≥ LE involvement)
    - Dystonia: hypertonia and reduced movement
    - Choreoathetosis: irregular spasmodic involuntary movements of the limbs or facial muscles
    - Ataxia: loss of orderly muscular coordination
  - Motor function severity
    - The Gross Motor Function Classification System (GMFCS) scores I to V are the following:
      - Score of I: ambulates without limitation
      - Score of II: ambulates without assistive devices but some limitation
      - Score of III: ambulates with assistive mobility devices
      - Score of IV: self-mobility limited, but technology can help
      - Score of V: self-mobility severely limited, even with technology
The Manual Ability Classification System (MACS) can be used to assess UE and fine motor function.

DIFFERENTIAL DIAGNOSIS
Benign congenital hypotonia, brachial plexus injury, familial spastic paraplegia, dopa-responsive dystonia, transient toe walking, muscular dystrophy, metabolic disorders (e.g., glutaric aciduria type 1), mitochondrial disorders, genetic disorders (e.g., Rett syndrome)

DIAGNOSTIC TESTS & INTERPRETATION
CP is a clinical diagnosis based on history, physical, and risk factors. Laboratory testing is not needed to make diagnosis but can help exclude other etiologies.

- Testing for metabolic and genetic syndromes (2)[C]
  - Not routinely obtained in the evaluation for CP
  - Considered if no specific etiology is identified by neuroimaging or there are atypical features in clinical presentation
  - Detection of certain brain malformations may warrant genetic or metabolic testing to identify syndromes.
- Screening for coagulopathies: Diagnostic testing for coagulopathies should be considered in children with hemiplegic CP with cerebral infarction identified on neuroimaging (2)[C].

Initial Tests (lab, imaging)
- Neuroimaging is not essential, but it is recommended in children with CP for whom the etiology has not been established (2)[C].
- MRI is preferred to CT if need to determine etiology and timing of a brain insult (2)[C].
- Abnormalities found in 80–90% of patients: brain malformation, cerebral infarction, intraventricular or other intracranial hemorrhage, periventricular leukomalacia, ventricular enlargement, or other cerebrospinal fluid (CSF) space abnormalities

Diagnostic Procedures/Other
- The Communication Function Classification System has recently been developed as another means of assessing verbal performance.
- International Classification of Functioning, Disability and Health for CP have been newly developed to standardize functional assessments.
- Screening for comorbid conditions: developmental delay/intellectual impairment, vision/hearing impairments, speech and language disorders, feeding/swallowing dysfunction, or seizures
- Electroencephalograms (EEGs) should only be obtained if there is a history of suspected seizures.

Test Interpretation
Perinatal brain injury may include the following:
- White matter damage
  - Most common in premature infants
  - Periventricular leukomalacia: gliosis with or without focal necrosis with resulting cysts and scarring; may be multiple lesions of various ages. Necrosis can lead to cysts/scarring.
  - Germinal matrix hemorrhage: may lead to intraventricular hemorrhage
- Gray matter damage: more common in term infants; cortical infarcts, focal neuronal damage, myelination abnormalities
TREATMENT

Focuses on control of symptoms; treatments reduce spasticity to prevent painful contractures, manage comorbid conditions, and optimize functionality and quality of life.

GENERAL MEASURES

- Early intervention referral for children 0–3 years improves motor and cognitive outcomes (3) [A].
- Various therapy modalities enhance functioning:
  - Physical therapy to improve posture stability and gait, motor strength and control, and prevent contractures
  - Occupational therapy to increase functional activities of daily living and other fine motor skills
  - Speech therapy for verbal and nonverbal speech and to aid in feeding
- Equipment optimizes participation in activities:
  - Orthotic splinting (ankle–foot orthosis) maintains functional positioning and prevents contractures.
  - Spinal bracing (body jacket) may slow down scoliosis.
  - Augmentative communication with pictures, switches, or computer systems for nonverbal individuals
  - Therapeutic and functional electrical stimulation decreases activity limitation in gait.
  - Use of adaptive equipment such as crutches, walkers, gait trainers, and wheelchairs for mobility and standers for weight-bearing

MEDICATION

First Line

- Diazepam (4)[A]
  - A γ-aminobutyric acid-A (GABA_A) agonist that facilitates CNS inhibition at spinal and supraspinal levels to reduce spasticity
  - Used for short-term treatment for generalized spasticity; insufficient evidence on motor function
  - Adverse effects: ataxia and drowsiness
  - Adult dose: 2 to 12 mg/dose PO q6–12h
  - Pediatric dose (<12 years and <15 kg): <8.5 kg: 0.5 to 1.0 mg HS; 8.5 to 15.0 kg: 1 to 2 mg HS; children 5 to 16 years of age and ≥15 kg: 1.25 mg TID

- Botulinum toxin type A (4)[A]
  - Acts at neuromuscular junction to inhibit the release of acetylcholine to reduce tone
  - Injected directly into muscles of interest for localized spasticity; insufficient evidence on motor function
  - Higher functional benefit when combined with occupational therapy
  - Lasts for 12 to 16 weeks following injection

Second Line

- Baclofen (4)[A]
  - A GABA_B agonist, facilitates presynaptic inhibition of mono- and polysynaptic reflexes
  - Adverse effects: drowsiness and sedation
– Abrupt withdrawal symptoms: spasticity, hallucinations, seizures, confusion, hyperthermia
– Adults: Initial dose is 5 mg TID; increase dosage every 3 days to an average maintenance
dose of 20 mg TID, 80 mg/day maximum.
– Pediatric dose (>2 years): initial 10 to 15 mg/day. Titrate to effective dose (maximum 40
mg/day). <8 years old: 60 mg/day maximum; >8 years old: 60 mg/day maximum

Intrathecal baclofen (baclofen pump) (5)[A]
– Continuous intrathecal route allows greater maximal response with smaller dosage to reduce
spasticity.
– May help ambulatory individuals with gait but no improvement seen in nonambulatory
patients
– Adverse effects: infection, catheter malfunction, CSF leakage

ADDITIONAL THERAPIES
• Multidisciplinary care including ophthalmology; neurology; orthopedics; physiatry along with
physical, occupational, and speech therapists
• A primary care “medical home” that coordinates medical and community services, provides
support for the patient and the patient’s family

SURGERY/OTHER PROCEDURES
• Dorsal root rhizotomy selectively cuts dorsal rootlets from L1–S2. Best for patients with
normal intelligence with spastic diplegia. Decreases spasticity in lower limbs when done in
conjunction with physiotherapy but associated with adverse effects. Evidence is lacking as to
long-term outcomes.
• Surgical treatment of joint dislocations/subluxation, scoliosis management, tendon
lengthening, gastrostomy

COMPLEMENTARY & ALTERNATIVE MEDICINE
• Therapeutic horse riding or hippotherapy improves postural control and balance.
• Aquatherapy improves gross motor function in patients with various motor severities (6)[B].

ONGOING CARE

PROGNOSIS
Reduced lifespan strongly associated with level of functional impairment and intellectual
disability

ADDITIONAL READING

CODES

ICD10

- G80.9 Cerebral palsy, unspecified
- G80.1 Spastic diplegic cerebral palsy
- G80.2 Spastic hemiplegic cerebral palsy

CLINICAL PEARLS

- Management should focus on maximizing functioning and quality of life using multidisciplinary team approach.
- Regression of motor skills does not occur with CP.
CERVICAL HYPEREXTENSION INJURIES
Shane L. Larson, MD ● Rita A. Kostecke, MD

BASICS

DESCRIPTION
- Class of neck injuries typically seen in rapid, forceful extension of the cervical spine
- Flexion–extension injuries ("whiplash") are usually from motor vehicle accidents (MVAs).
- Other causes include falls, violence, or sports (1).
- May involve:
  - Injury to vertebral and paravertebral structures: fractures, dislocations, ligamentous tears, and disc disruption/subluxation
  - Spinal cord injury (SCI): traumatic central cord syndrome (CCS) secondary to cord compression or vascular insult, SCI without radiologic abnormality (SCIWORA)
  - Blunt cerebrovascular injury (BCVI): vertebral artery or carotid artery dissection
  - Soft tissue injury: cervical strain/sprain (i.e., whiplash), cervical stingers (see “Brachial Plexopathy”)

EPIDEMIOLOGY
- Predominant age: SCI average age of injury 43 years, CCS average age 53 years
- Trauma and sports injuries are more common in young adults (average age 29 years).
- About 78% of new SCI cases are male (1).

Incidence
In the United States
- Cervical fractures: 2 to 5/100 blunt trauma patients
- CCS: 4/100,000 people/year
- BCVI: estimated 1/1,000 of hospitalized trauma patients; incidence increased with cervical spine or thoracic injury.
- Cervical strain: 3 to 4/1,000 people/year
- Whiplash is the most common injury in MVAs and accounts for 28% of all ED visits for MVAs.
- Incidence of whiplash is 70 to 328/100,000 with rates highest in 20- to 24-year-old females.
- 2–6% of patients with blunt trauma have SCI.
- The incidence of traumatic SCI is approximately 54 cases per million population per year (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Blunt trauma due to MVAs, falls, sports injuries, and violence (primarily gunshot wounds)

RISK FACTORS
- Whiplash: initial injury, no seat belt use, female gender
- Chronic pain and/or disability: litigation, previous neck pain or injury, female gender, report of headache/low back pain at onset, low education level (2)[C]
- Fractures: osteoporosis, conditions predisposing to spinal rigidity, such as ankylosing spondylitis or other spondyloarthopathies
- CCS: preexisting spinal stenosis present in >50%
– Acquired: prior trauma, spondylosis
– Congenital: Klippel-Feil syndrome (congenital fusion of any two cervical vertebrae)

**GENERAL PREVENTION**
Seat belts, use of proper safety equipment, rule changes for sports activities, and proper technique in sports activities can prevent or minimize injury.

**COMMONLY ASSOCIATED CONDITIONS**
Closed head injuries, whiplash-associated disorders (WAD), SCI, soft tissue trauma

**DIAGNOSIS**

**HISTORY**
Usually acute presentation with mechanism of cervical hyperextension and complaints of neck pain, stiffness, or headaches ± neurologic symptoms; include Glasgow Coma Scale (GCS).

**PHYSICAL EXAM**
- External signs of trauma on the head and neck such as abrasions, lacerations, or contusions provide clues to mechanism and associated injuries.
- Presence, severity, and location of neck tenderness help localize involved structure(s):
  - Posterior, midline bony tenderness raises concern for underlying fracture.
  - Paraspinal or lateral soft tissue tenderness suggests muscular/ligamentous injury.
  - Anterior tenderness concerning for vascular injury
- Carotid bruit suggests carotid dissection.
- Neurologic exam: Paresthesias, weakness suggests SCI or stroke secondary to BCVI:
  - CCS often presents as
    - Distal > proximal symptom distribution, upper extremity > lower extremity
    - Extremity weakness/paralysis predominates.
    - Variable sensory changes below level of lesion (including paresthesias and dysesthesia)
    - Bladder/bowel incontinence may occur.

**DIFFERENTIAL DIAGNOSIS**
- Acute or chronic disc pathology (herniation or internal disruption)
- Osteoarthritis
- Cervical radiculopathy
- For CCS
  - Bell cruciate palsy
  - Bilateral brachial plexus injuries
  - Carotid or vertebral artery dissection

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Low-risk patients can be cleared clinically (without imaging) using either the Canadian C-Spine Rule (CCR) or the National Emergency X-Ray Utilization Study (NEXUS) criteria (3) [B]:
  - CCR: Stable, ≥16-year-old patient with acute head and neck trauma and no history of cervical spine disease/surgery can be cleared if all of the following conditions are met:
- GCS ≥15
- No dangerous mechanism or extremity paresthesias
- Age <65 years
- At least one “low-risk factor” (i.e., simple rear-end MVA, ambulation at the accident scene, no midline cervical tenderness, delayed onset of neck pain, or sitting at the time of exam)
  - NEXUS: clinically clear if all of the following:
    - No posterior, midline C-spine tenderness
    - No evidence of intoxication
    - Normal level of alertness
    - No focal/neurologic deficits
    - No distracting injury
  - Reported sensitivity/specificity: CCR (90–100%/1–77%), NEXUS (83–100%/13–46%) (4)

In patients with high-risk mechanism or concerning historical/physical exam, recommend imaging based on the suspected injury and level of clinical suspicion:
- Plain radiographs: in some patients who cannot be cleared clinically but are still in low-suspicion category: sensitivity for C-spine injury 39%:
  - Dynamic: flexion–extension; only if asymptomatic and no neurologic deficits or mental impairment, poor identification of ligamentous injury, limited diagnostic value
- Axial computed tomography (CT) from occiput to T1 with coronal and sagittal reconstructions has replaced plain radiography as the test of choice for cases with moderate to high clinical suspicion of C-spine injury, given high sensitivity (90–100%).
- Magnetic resonance imaging (MRI): test of choice in CCS with direct visualization of traumatic cord lesions (edema or hematomyelia), soft tissue compressing cord, and/or stenosis of canal; detects ligamentous injury and abnormalities of intervertebral discs and soft tissues; MRI is less helpful for fractures.
- CT angiography: visualization of cervical and cerebral vascular structures to detect BCVI, sensitivity approaches 100% when a ≥16-slice CT scanner is used. MR angiography is an alternative, although sensitivity of 47–50% limits utility.

**Test Interpretation**
- CCS: thought to be due to white matter axonal disruption of the lateral column, particularly the corticospinal tracts
- BCVI: intimal disruption, leading to thrombosis and embolization
- Acute cervical strain/sprain: Models suggest myofascial tearing, edema, and inflammation.

**Geriatric Considerations**
- Degenerative changes of the C-spine may be confused with acute traumatic change; osteopenia may limit fracture visualization on x-ray—CT is more accurate.
- Degenerative disease and osteopenia increase risk of upper cervical spine injuries (even with low-velocity trauma).

**Pediatric Considerations**
SCIWORA: high incidence at <9 years accounting for up to 50% of pediatric cervical spine injuries. MRI helps detect injury.
**TREATMENT**

**GENERAL MEASURES**

- **Whiplash/WAD**
  - Limited or no benefit to cervical collar. If provided, use for <72 hours.
  - No advantage to engaging early multiprofessional intervention (e.g., pain management and psychology (4)[C]
  - No outcome differences with physical therapy (PT) versus passive (immobilization, rest) treatment; advance activity levels as tolerated.
  - No preferred approach to treatment in absence of fracture

- **Fractures**
  - Stability determined by imaging
  - Decompression and stabilization are indicated for:
    - Incomplete SCIs with spinal canal compromise
    - Clinical deterioration or failure to improve despite conservative management
  - **Hangman fracture**: traumatic spondylolisthesis of C2 with bilateral fractures through C2 pedicles, often with anterior subluxation of C2 over C3; can be unstable:
    - Managed with halo vest immobilization for 12 weeks until flexion–extension films normal
  - **Odontoid fractures**: treat according to type:
    - I: through apex; usually stable; external immobilization with a cervical collar (less often halo vest) for up to 12 weeks
    - II: most common, at base of dens, usually unstable; nonunion rates of up to 67% with halo immobilization alone, especially with dens displacement >6 mm or age >50 years
    - III: through C2 body, usually stable; immobilization in halo or cervical collar for 12 to 20 weeks
  - **Hyperextension teardrop fractures**
    - If stable, rigid collar or cervicothoracic brace for 8 to 14 weeks
    - If unstable, halo brace for up to 3 months

- **CCS**: neck immobilization with cervical collar, PT/occupational therapy (OT)

- **Cervical strain**: no difference in outcomes with active (PT) versus passive (immobilization, rest) treatment; may use soft cervical collar for 10 days for symptomatic relief and then mobilize and increase activity as tolerated; no clear EBM guidelines

**MEDICATION**

- **Fractures**: pain control with analgesics

- **CCS**: Within 8 hours of injury, consider methylprednisolone 30 mg/kg IV over 15 minutes and then continuous infusion 5.4 mg/kg/hr IV for 23 hours. Further improvement in motor function recovery may be seen if infusion is continued for 48 hours, especially if initial bolus administration is delayed after injury (5,6)[A].

- **BCVI**: Anticoagulation with IV heparin, followed by warfarin therapy for 3 to 6 months and then long-term antiplatelet therapy; antiplatelet agent as sole initial therapy in patients with contraindications to anticoagulation

- **Cervical strain**: nonsteroidal anti-inflammatory drugs or acetaminophen. There is little benefit to adding cyclobenzaprine for acute cervical strain.
ISSUES FOR REFERRAL
- If cervical spine injury is suspected, immobilize patient and send to ED for evaluation and clearance.
- Emergent consultation from a spine surgeon for any concern for unstable fracture or SCI

SURGERY/OTHER PROCEDURES
- Fractures
  - Hangman fracture: surgical fixation for excessive angulation or subluxation, disruption of intervertebral disc space, or failure to obtain alignment with external orthosis
  - Odontoid fractures
    - Type II: Early surgical stabilization is recommended in setting of age >50 years, dens displacement >5 mm, and specific fracture patterns.
    - Type III: Surgical intervention is often reserved for cases of nonunion/malunion after trial of external immobilization.
- CCS: Surgical decompression/fixation is indicated in setting of unstable injury, herniated disc, or when neurologic function deteriorates.
- BCVI: Surgical and/or angiographic intervention may be required if there is evidence of pseudoaneurysm, total occlusion, or transection of the vessel.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Varies by injury; clinical judgment, imaging findings, concomitant injuries, and need for operative intervention
- Advanced Trauma Life Support protocol with backboard and collar

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Follow patients with known injuries using serial imaging under the care of a specialist.

PATIENT EDUCATION
ThinkFirst Foundation: http://www.thinkfirst.org

PROGNOSIS
- Presenting neurologic status is the most important factor in determining prognosis.
- Fractures
  - Hangman fracture: 93–100% fusion rate after 8 to 14 weeks external immobilization
  - Odontoid fracture, fusion rate by type: type I, ~100% with external immobilization alone; type II, nonunion rates of up to 67% with halo immobilization alone, especially with dens displacement >6 mm or age >50 years; type III, 85% with external immobilization, 100% with surgical fixation
- BCVI: Patients have fewer neurologic sequelae with early diagnosis and antithrombotic therapy.
- CCS
  - Spontaneous recovery of motor function in >50% over several weeks. Younger patients are more likely to regain function.
Leg, bowel, and bladder functions return first, followed by upper extremities.

- WAD: Prognostic factors for development of late whiplash syndrome (>6 months of symptoms affecting normal activity) include increased initial pain intensity, pain-related disability, and cold hyperalgesia.

**COMPPLICATIONS**

- Fractures: instability or malunion/nonunion necessitating second operation, reactions, and infection related to orthosis
- BCVI: embolic ischemic events and pseudoaneurysm formation

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- S13.4XXA Sprain of ligaments of cervical spine, initial encounter
- S13.101A Dislocation of unspecified cervical vertebrae, init encntr
- S14.109A Unsp injury at unsp level of cervical spinal cord, init
CLINICAL PEARLS

- Use NEXUS or CCR to determine need for imaging in every patient with a potential neck injury.
- Always perform imaging if clinical judgment suggests the need to do so.
- Inquire about preexisting cervical spine conditions, especially in the elderly, because this may increase risk of injury or change radiographic interpretation.
- Suspect SCI until fully cleared through exam and imaging.
- Consider BCVI when neurologic deficits are inconsistent with level of known injury or in the setting of a significant mechanism of injury.
BASICS

DESCRIPTION
- Most cervical cancers begin in the transformation zone.
- 60–75% are from squamous epithelium and 25–40% are glandular.

EPIDEMIOLOGY

Incidence
- Cervical cancer is the second most common malignancy in women worldwide and the most common gynecologic cancer.
- The disease has a bimodal distribution, with the highest risk among women aged 40 to 59 years and >70 years. However, in recent years, there has been an increase in incidence in women aged 30 to 35 years.

Prevalence
- In 2018, the American Cancer Society (ACS) estimates 13,240 new cases of invasive cancer and 4,170 deaths in the United States.
- In the United States, Hispanic women are at highest risk followed by African Americans, Asians, and whites. American Indians and Alaskan natives have the lowest risk, perhaps attributed to low screening rates.

ETIOLOGY AND PATHOPHYSIOLOGY
- Human papillomavirus (HPV) infection is the most important etiologic factor. Infection with serotypes 16 and 18 account for 70% of all cervical cancer.
- Persistent HPV infection promotes coding errors in the cell cycle, resulting in dysplastic changes to the endocervical cellular lining. In addition, HPV activates E6 and E7 oncogenic proteins, which in turn inactivate p53 and Rb tumor suppressor genes.
- Tumor growth is via lymphatic and hematogenous spread (Halstedian growth).

RISK FACTORS
- Persistent HPV infection is the primary risk factor for developing cervical cancer.
- HPV infection has high prevalence with nearly 80 million people infected in the United States and 14 million new cases each year worldwide.
- Other risk factors include:
  - Lack of or decreased access to health care and ability to obtain regular Pap smears
  - Early coitarche
  - Multiple sexual partners
  - Unprotected sex
  - A history of sexually transmitted diseases (STDs)
  - Low socioeconomic status
  - Obesity (increases the risk for adenocarcinoma type)
– High parity (>3 full-term deliveries)
– Cigarette smoking (doubles the risk)
– Immunosuppression (HIV/AIDS, chemotherapy)
– Diethylstilbestrol (DES) exposure in utero

**GENERAL PREVENTION**

- Education on vaccination, safe sex practices, and smoking cessation are the cornerstone of prevention.
- HPV vaccines protect against the most common HPV strains associated with cervical cancer development, 16 and 18, as well the strains responsible for warts (6 and 11).
- There are three kind of FDA-approved vaccines, Gardasil 4, Gardasil 9, and Cervarix.
- Vaccination is recommended for:
  - Girl and boys ages 11 or 12 years, respectively, in 2 doses with 6 to 12 months apart
  - Children ≥14 years should receive 3 doses over the course of 6 months.
  - Immunocompromised patients ages 9 through 26 years, men who have sex with men, and the LGBTQ community
  - Women ages 9 through age 26 years
  - Men ages 9 through age 21 years
- Routine screening with Pap smear (or HPV testing) is virtually the only way to identify premalignant lesions and possibly prevent progression to cancer. Screening has the potential to prevent up to 80% of cervical cancer worldwide.
- Current guidelines from the American College of Obstetricians and Gynecologists (ACOG) and the American Society for Colposcopy and Cervical Pathology (ASCCP) screening should be performed as follows:
  - Cytology alone every 3 years between 21 and 29 years of age (1)[A]
  - Cytology plus HPV testing every 5 years after 30 years (1)[A]. The International Federation of Gynecology and Obstetrics (FIGO) recommends visual inspection with acetic acid (VIA) or Lugol iodine (VILI) as alternatives to Pap smears in resource-poor settings (2)[C].
- Despite HPV vaccination, cervical cancer screening will remain the main preventive measure for both vaccinated and unvaccinated women.

**COMMONLY ASSOCIATED CONDITIONS**

- Condyloma acuminata
- Preinvasive/invasive lesions of the vulva, vagina, oral and oropharyngeal cancers

**DIAGNOSIS**

**HISTORY**

- Patient with HPV infection may be asymptomatic. The most common symptom is postcoital vaginal bleeding. Other symptoms are intermenstrual or postmenopausal bleeding and vaginal discharge.
- Less common symptoms include low back pain with radiation down posterior leg, lower extremity edema, vesicovaginal and rectovaginal fistula, and urinary symptoms.

**PHYSICAL EXAM**

- Thorough pelvic exam is essential:
  - Many patients have a normal exam, especially with microinvasive disease.
– Lesions may be exophytic, endophytic, polypoid, papillary, ulcerative, or necrotic.
– May have watery, purulent, or bloody discharge

- Bimanual and rectovaginal examination should be performed to evaluate uterine size; vaginal wall; rectovaginal septum; and parametrial, uterosacral, and pelvic sidewall involvement.
- Enlarged supraclavicular or inguinal lymphadenopathy, lower extremity edema, ascites, or decreased breath sounds with lung auscultation may indicate metastases or advanced stage disease.

DIFFERENTIAL DIAGNOSIS
- Marked cervicitis and erosion
- Glandular hyperplasia
- Sexually transmitted infections
- Cervical condyloma, leiomyoma, or polyp
- Metastasis from endometrial carcinoma or gestational trophoblastic neoplasia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Colposcopy with directed biopsies and/or biopsy of gross lesions are the definitive means of diagnosis.
- CBC may show anemia.
- Urinalysis may show hematuria.
- In advanced disease, BUN, creatinine, and liver function tests (LFTs) may be helpful.
- CT scan of the chest, abdomen, and pelvis and/or a positron emission tomography (PET) scan for metastatic workup
- Apart from chest x-ray (CXR) and intravenous pyelogram (IVP), imaging does not alter tumor stage.
- MRI may be helpful in evaluating parametrial involvement in patients who are surgical candidates or for radiation treatment planning.

Follow-Up Tests & Special Considerations
- Exam under anesthesia may be helpful in determining clinical stage, disease extent, and suitability for surgery.
- Endocervical curettage and cervical conization as indicated to determine depth of invasion and presence of lymphovascular involvement
- Cystoscopy to evaluate bladder invasion
- Proctoscopy for invasion into rectum

Test Interpretation
- Majority of cases are invasive squamous cell types arising from the ectocervix.
- Adenocarcinomas arise from endocervical mucus-producing glandular cells. Often, a “bulky,” “barrel-shaped” cervix is present on exam.
- Other cell types include rare mixed cell types, neuroendocrine tumors, sarcomas, lymphomas, and melanomas.

TREATMENT

GENERAL MEASURES
Improve nutritional state, correct anemia (Hb <12 g/dL), and treat pelvic infections.

**MEDICATION**

- Chemoradiation with cisplatin-containing regimen has superior survival over pelvic and extended-field radiation alone.
- Neoadjuvant chemotherapy may improve survival for early and locally advanced tumors, but more data are needed (3)[A].
- Adjuvant chemotherapy after chemoradiation may improve progression-free survival in patients who receive primary chemoradiation for stages IIB to IVA tumors. The OUTBACK trial will further investigate these findings (http://www.clinicaltrials.gov).
- The addition of the antiangiogenesis drug bevacizumab to standard combination chemotherapy (cisplatin/topotecan or cisplatin/paclitaxel) for recurrent, persistent, or metastatic disease has been shown to improve overall survival (4)[A].

**ISSUES FOR REFERRAL**

Multidisciplinary management of patients as needed and in a timely fashion

**ADDITIONAL THERAPIES**

- Chemoradiation (without surgery) is the first-line therapy for tumors stage IIB and higher (gross lesions with obvious parametrial involvement) and for most bulky stage IB2 tumors.
- Combination of external beam pelvic radiation and brachytherapy is usually employed.
- If para-aortic lymph node metastases are suspected, extended-field radiation or lymph node dissection prior to radiation therapy may be performed.

**SURGERY/OTHER PROCEDURES**

- Surgical management is an option for patients with early-stage tumors.
- Removal of precursor lesions (cervical intraepithelial neoplasia [CIN]) by loop electrosurgical excision procedure (LEEP), cold knife conization, laser ablation, or cryotherapy. Stage IA1 (lesions with <3-mm invasion from basement membrane) without lymphovascular space invasion: option of conization or simple extrafascial hysterectomy
- Stage IA2 (lesions with >3-mm but <5-mm invasion from basement membrane): option of radical hysterectomy with lymph node dissection or radiation depending on clinical setting. Robotic radical hysterectomy (RRH) has demonstrated to be superior to laparoscopic radical hysterectomy and open radical hysterectomy in intraoperative blood loss, length of hospital stay, and intraoperative and postoperative complications; RRH can be regarded as a safe and effective therapeutic procedure for the management of cervical cancer (5).
- Stages IA2 to IB1: Fertility-sparing radical trachelectomy may be considered in selected patients.
- Stages IB1 to IIA (gross lesions without obvious parametrial involvement): option of radical hysterectomy with lymph node sampling or primary chemoradiation with brachytherapy and teletherapy, depending on clinical setting. In stage IB, when comparing adjuvant radiotherapy with no adjuvant radiotherapy, there is no significant difference in survival at 5 years between women who received radiation and those who received no further treatment (risk ratio [RR] = 0.8, 95% confidence interval [CI] 0.3–2.4). However, women who received radiation had a significantly lower risk of disease progression at 5 years (RR 0.6, 95% CI 0.4–0.9) (6).
- Stage IVA (lesions limited to central metastasis to the bladder and/or rectum): Primary pelvic exenteration may be feasible.
- Stage IVB disease is treated with goal of palliation. Early referral to palliative care should be
Pregnancy Considerations

- Management is guided by consideration of stage of lesion, gestational age, and maternal assessment of risks and benefits from treatment.
- Abnormal cytology is best followed up by colposcopy with directed biopsies.
- In pregnant women diagnosed with cervical cancer before 16 weeks of gestation, treatment should be started immediately.
- In pregnant women with early stages (IA1, IA2, IB) diagnosed after 16 weeks of gestation, treatment may be delayed to allow for fetal maturity.
- In pregnant women with advance disease (stage IB2) diagnosed after 16 weeks, treatment may be based on gestational age at the time of diagnosis. Microinvasive carcinoma: conization or trachelectomy. If depth of invasion ≤3 mm, follow up at the 6-week postpartum visit.
- Invasive carcinoma requires definitive therapy, with timing determined by maternal preference, stage of disease, and gestational age at the time of diagnosis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Signs of active bleeding
- Urinary symptoms
- Dehydration
- Complications from surgery, chemotherapy, or radiation
- Active vaginal bleeding can be controlled with timely vaginal packing and radiation therapy.
- Recognition of ureteral blockage, hydronephrosis, urosepsis, and timely intervention
- Discharge criteria based on multidisciplinary assessment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- With completion of definitive therapy and based on individual risk factors, patients are evaluated with physical/pelvic examinations:
  - Every 3 to 6 months for 2 years
  - Every 6 to 12 months until the 5th year
  - Yearly thereafter
- Pap smears may be performed yearly but have a low sensitivity for detecting recurrence.
- CT and PET scan are useful in locating metastases when recurrence is suspected.
- Signs of recurrence include vaginal bleeding, unexplained weight loss, leg edema, and pelvic or thigh pain.

PATIENT EDUCATION

- ACOG at [http://www.acog.org](http://www.acog.org)
PROGNOSIS
- If detected early, invasive cervical cancer can be treated successfully.
- The 5-year survival rate for early stage (stage 1A, in which the cancer has minimal spread to the inside of the cervix) is estimated at 92%.
- An elevated squamous cell carcinoma antigen (SCC-Ag) serum levels estimated by ELISA technique can be used to predict the clinical response to neoadjuvant chemotherapy and residual disease. Persistently elevated SCC-Ag level at 2 to 3 months after RT had a significantly higher incidence of treatment failure.
- Serum SCC-Ag levels are also useful for monitoring treatment efficacy, disease progression, recurrence, and poor prognosis in SCCs. The combination of clinical pelvic examination and SCC-Ag levels provides useful information for the further need of treatment.

COMPLICATIONS
- Loss of ovarian function from radiotherapy or indication for bilateral oophorectomy
- Hemorrhage
- Pelvic infection
- Genitourinary fistula
- Bladder dysfunction
- Sexual dysfunction
- Urinary obstruction with renal failure
- Bowel obstruction
- Pulmonary embolism
- Lower extremity lymphedema

REFERENCES

ADDITIONAL READING
Cervical cancer is the second most common malignancy in women worldwide. Improving access to screening is likely to have the greatest impact in reduction of the burden of disease. Women with cervical cancer may be asymptomatic and have a normal physical exam. Surgical management is an option for patients with early-stage tumors. Chemoradiation is the first-line therapy for higher stage tumors.
CHICKENPOX (VARICELLA ZOSTER)
Andrew J. Richardson, MD

BASICS

DESCRIPTION
- Highly contagious, generalized exanthem characterized by crops of pruritic vesicles on the skin and mucous membranes following exposure to varicella-zoster virus (VZV).
- VZV is spread by respiratory (airborne) droplets and direct contact with vesicles.
- VZV establishes latency in the dorsal root ganglia; reactivation results in zoster (shingles).
- Outbreaks tend to occur late winter through early spring in temperate climates.
- Usual incubation period is 14 to 16 days (range: 10 to 21 days). Patients are infectious from ~48 hours before appearance of vesicles until the final lesions have crusted. Historically, most people acquired chickenpox during childhood and develop lifelong immunity. Varicella is currently part of recommended primary vaccination schedule.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): varicella

EPIDEMIOLOGY
- Predominant age: peak incidence 3 to 9 years but may occur at any age
- Predominant gender: male = female

Incidence
- Decreasing incidence since routine vaccination; estimated 3.5 million cases annually prior to vaccine, with an incidence of 8–9% in children age 1 to 9 years
- Reported U.S. varicella cases: 1991: 147,076; 2017: 8,775 cases (1)
- Prior to vaccine, ~100 deaths per year were reported in the U.S.; in 2015, there were 6 reported deaths (1).
- U.S. rates: 1994, prior to vaccine: 136/100,000 persons; 2013 to 2014: <0.001/100,000 persons
- Rates of varicella in the United States dropped after vaccine introduction until mid-2000s when they plateaued; second dose of vaccine recommended in 2006, and rates have again declined
- In developing countries, varicella is still associated with a severe disease burden.
- Susceptible (immunologically naive) individuals exposed to varicella are at risk to develop disease and are also potentially infectious for 21 days.

ETIOLOGY AND PATHOPHYSIOLOGY
- Viral particles are inhaled via respiratory droplets where they invade respiratory epithelium. Replication in regional respiratory tract lymph nodes are followed by primary viremia (4–6 days after exposure). A second phase of viral replication and a secondary viremia (14–16 days after exposure) contributes to epidermal invasion and the characteristic skin lesions.
- Skin lesions are histologically identical to herpes simplex virus.
- In fatal cases, intranuclear inclusions are found in vascular endothelium and most organs.
- VZV is a double-stranded DNA virus of the α-Herpesviridae subfamily.
- Humans are primary disease reservoir.
RISK FACTORS
- No history of prior varicella infection or immunization
- Immunocompromised (especially children with leukemia/lymphoma in remission or receiving high-dose corticosteroids)
- Pregnancy

Geriatric Considerations
- Infection is more severe in adults.
- Reactivation of latent infection causes herpes zoster (shingles).
- The Centers for Disease Control and Prevention (CDC) recommends vaccinating all immunocompetent adults with the herpes zoster vaccine.
- Two forms of the vaccine are available. The recombinant zoster vaccine is currently preferred over the live attenuated vaccine.
- The recombinant zoster vaccine is administered as a 2-dose series separated by 2 to 6 months and can be given as early as age 50 years. This vaccine can be given to patients with a history of shingles or who have already had a dose of the live attenuated zoster vaccine (https://www.cdc.gov/vaccines/vpd/shingles/hcp/shingrix/recommendations.html).
- The live attenuated zoster vaccine can still be used as a single-dose vaccine for patients ≥60 years but should not be used in patients who are immunocompromised, such as those with HIV, on chronic steroid therapy, on chemotherapy, or those who have cancers affecting the bone marrow or lymphatic system (lymphoma, leukemia, etc.)
- Primary viral pneumonia is the most common cause of death from varicella.

Pediatric Considerations
- Neonates born to mothers who develop chickenpox from 5 days before to 2 days after delivery are at risk for serious disease and should receive varicella-zoster immune globulin (VZIG).
- Newborns are at highest risk for severe disease during the 1st month of life, especially if mother is seronegative.
- Delivery prior to 28 weeks increases risk.
- Varicella bullosa is seen mainly in children <2 years. Lesions appear as bullae instead of vesicles. The clinical course is otherwise similar.
- Septic complications and encephalitis are the most common causes of death from zoster in children.
- Avoid aspirin/acetylsalicylic acid in children because of link to Reye syndrome.

Pregnancy Considerations
- 25% risk of transplacental infection after maternal infection
- Congenital malformations are seen in 2% of patients when the fetus is infected during the 1st or 2nd trimester, characterized by limb atrophy, cutaneous scarring, and occasional central nervous system (CNS) and eye manifestations.
- Morbidity (e.g., pneumonia) is increased in women infected during pregnancy.

GENERAL PREVENTION
- Isolate hospitalized patients.
- When indicated, administer passive immunization using VZIG within 96 hours (can be as long as up to 10 days) after exposure. VZIG recommended for:
  - Patients exposed to chickenpox or shingles who are immunocompromised, newborns of mothers with onset of chickenpox <5 days before delivery or <2 days after delivery,
premature infants (<28 weeks) exposed in neonatal period either whose mothers are not immune, or babies who weigh <1,000 g regardless of maternal immunity.

- Active immunization prevents or reduces the severity of varicella if given within 72 hours of exposure.
- Active immunization: varicella virus vaccine (Varivax): live attenuated vaccine recommended by Advisory Committee on Immunization Practices (ACIP) for immunization of healthy patients ≥12 months who have not had chickenpox
  - 12 months to 12 years: initial dose 0.5 mL SC at age 12 to 15 months; second dose at age 4 to 6 years. Single dose is 85–94% effective in preventing severe disease. The 2-dose regimen is 96–98% effective. Breakthrough disease generally has <50 lesions, shorter duration, and lower fever incidence [A].
  - ≥13 years: two 0.5 mL SC doses 4 to 8 weeks apart, seroconversion rates 78–82% after 1 dose, 99% after 2 doses; adult efficacy in lower end of this range
  - 2014 U.S. estimate: 91% one or more dose vaccine coverage for children 19 to 35 months [3]
  - Vaccine side effects are pain and redness at the vaccine site (19% of children; 24% of teens and adults). 1 in 10 develops fever. 1 in 25 will develop a mild varicella-like rash up to 1 month after vaccination.
  - Vaccine contraindications
    - Severe allergic reaction (e.g., anaphylaxis) to a previous dose or vaccine component
    - Severe immunodeficiency (e.g., HIV patients with very low CD4 counts, chemotherapy, congenital immunodeficiency, long-term immunosuppressive therapy)
    - Pregnancy
- MMRV vaccine, combines the measles, mumps, and rubella vaccine with varicella, is equally effective. There are rare reports of an increased risk of febrile seizures 5 to 12 days after vaccination in 1/2,300 to 2,600 patients.
- May be considered for a subset of HIV-positive children in CDC class I with CD4 >25%
  - Vaccine recipients who develop a rash should avoid contact with immunocompromised people, pregnant women who have never had chickenpox, and their newborns.
  - Allow at least 3 months between doses 1 and 2 in children needing catch-up vaccination.

**DIAGNOSIS**

**HISTORY**
- Prodromal symptoms: fever, malaise, anorexia, mild headache
- Malaise, muscle aches, arthralgias, and headache are more common in adults.
- Subclinical in ~4% of cases
- Characteristic rash

**PHYSICAL EXAM**
- Characteristic rash: crops of vesicles on erythematous bases (“dew drops on a rose petal”)
- Lesions erupt in successive crops.
- Progress from macule to papule to vesicle and then begin to crust
- Pruritic rash is present in various stages of development.
- Lesions may be present on mucous membranes, both oral and vaginal.
DIFFERENTIAL DIAGNOSIS
- Herpes simplex: herpes zoster
- Smallpox
- Impetigo
- Coxsackievirus infection
- Scabies
- Dermatitis herpetiformis
- Drug rash
- Rickettsial pox infection

DIAGNOSTIC TESTS & INTERPRETATION
The diagnosis of chickenpox is primarily clinical. Testing is generally reserved for complicated cases or epidemiologic studies.

Initial Tests (lab, imaging)
- VZV polymerase chain reaction (PCR) is the current method of choice (best is fluid from intact vesicle).
- Leukocyte count varies; marked leukocytosis suggests secondary infection.
- Multinucleated giant cells on Tzanck smear from vesicle scrapings
- Isolate virus from human tissue culture technically difficult (positive in <40% of cases)
- Direct immunofluorescence is more sensitive and quicker to perform

Follow-Up Tests & Special Considerations
- Serologies show acute (IgM) or prior (IgG) infection.
- Visualization by electron microscopy, tissue culture (costly), and various methods of acute and convalescent sera collection: latex agglutination (most available), enzyme immunoassay, indirect immunofluorescence antibody, fluorescent antibody to membrane assay, or PCR assay, which can detect wild from vaccine viral strains
- Vaccine-modified cases can be more difficult to diagnose; PCR testing of skin lesions is most sensitive and specific for diagnosing varicella, especially in vaccinated persons.

TREATMENT
Generally outpatient, except for complicated cases

GENERAL MEASURES
- Supportive/symptomatic treatment
- Antihistamines and/or oatmeal baths for itch
- Acetaminophen and/or ibuprofen for pain and fever
- Clipping nails can help prevent scarring or secondary infection from excessive itching.

MEDICATION
First Line
- Supportive: antipyretics for fever; avoid aspirin in children.
- Local and/or systemic antipruritic agents for itching
- VZIG available for passive immunization for:
  - Immunocompromised patients, newborn infants of mothers who have signs and symptoms
of varicella at the time of delivery; premature infants born at 28 weeks or more whose mothers do not have evidence of immunity to varicella; premature infants <28 weeks’ gestation or who weigh <1,000 g regardless of maternal immunity
  – Give VZIG within 96 hours after exposure (4).
• Acyclovir: decreases duration of fever and shortens time of viral shedding; recommended for adolescents, adults, and high-risk patients; most beneficial if initiated early in the disease (≤24 hours)
  – 2- to 16-year-old patients: 20 mg/kg/dose (max 800 mg/dose) QID for 5 days
  – Adults: 800 mg 5 times daily for 5 days
• Contraindication
  – Hypersensitivity to the drug
• Precautions
  – Renal insufficiency with acyclovir
  – Concurrent administration of probenecid increases half-life; increased effects with zidovudine (e.g., drowsiness, lethargy)

Second Line
• Famciclovir: 500 mg TID for 7 to 10 days (adults)
• Valacyclovir: 1 g TID for 7 to 10 days (adults)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
The most common complications are secondary bacterial infection of skin and soft tissue (children) and pneumonia (adults). Severe complications include septicemia, necrotizing fasciitis, and osteomyelitis. Newborns and immunocompromised individuals are at higher risk of severe varicella.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Not needed in mild cases. Intensive supportive care may be required in the setting of complications.
• Activity as tolerated. Children may return to school when lesions have completely scabbed.

DIET
No special diet

PATIENT EDUCATION
• In otherwise healthy children, chickenpox is rarely serious and the recovery is almost always complete.
• Native chickenpox typically confers lifelong immunity.
• A second attack is rare, but subclinical infection can occur; occasionally, after vaccination in children
• Latent infection may recur years later as herpes zoster in adults (and sometimes in children).
• Fatalities are rare.

COMPLICATIONS
Although only 2% of cases are reported after 2nd decade, 35% of deaths occur in this age group:
- Secondary bacterial infection: cellulitis, abscess, erysipelas, sepsis, septic arthritis/osteomyelitis, or staphylococcal pyomyositis
- Pneumonia: 20–30% of adults with chickenpox have lung involvement; 1/400 is hospitalized.
- Encephalitis (the most common CNS complication)
- Meningitis; Reye syndrome
- Purpura, thrombocytopenia
- Glomerulonephritis; arthritis; hepatitis

REFERENCES

ADDITIONAL READING

SEE ALSO
Herpes Zoster (Shingles)

CODES
ICD10
- B01.9 Varicella without complication
- B02.9 Zoster without complications
- P35.8 Other congenital viral diseases

CLINICAL PEARLS
- Varicella zoster infection is more likely to produce serious illness in adults than in children.
- Introduction of the varicella vaccine has reduced morbidity and mortality. Currently, 2 doses of vaccine are recommended.
- Recombinant herpes zoster vaccine is recommended for immunocompetent persons $\geq 50$ years of age to decrease chance of shingles.
BASICS

DESCRIPTION
- Types of abuse: neglect (most common and highest mortality), physical abuse, emotional/psychological abuse, sexual abuse
- Neglect includes physical (e.g., failure to provide necessary food or shelter or lack of appropriate supervision), medical (e.g., failure to provide necessary medical or mental health treatment), educational (e.g., failure to educate a child or attend to special education needs), and emotional (e.g., inattention to a child’s emotional needs, failure to provide psychological care, or permitting the child to use alcohol or other drugs).
- System(s) affected: gastrointestinal (GI), endocrine/metabolic, musculoskeletal, nervous, renal, reproductive, skin/exocrine, psychiatric
- Synonym(s): suspected nonaccidental trauma; child maltreatment; child neglect

EPIDEMIOLOGY
Incidence
- Using the stringent “harm standard” definition, >1.25 million children experience maltreatment (1 in 58).
- Using the “endangerment standard,” 3 million children experienced maltreatment (1 child in 25).

Prevalence
Children’s Bureau report for federal fiscal year (FFY) 2017 (1):
- CPS agencies received an estimated 4.1 million referrals (national screened-in referral rate of 31.8 referrals per 1,000 children).
- Approximately 3.5 million children received either an investigation or alternative response. Of those investigated, 9.1 per 1,000 children were found to be victims of abuse or neglect.
- The overall rate of child fatalities was 2.32 deaths per 100,000 children in the national population. The rate of child fatalities is slightly higher in boys compared to girls.
- The majority of perpetrators were parents—one or both parents maltreated 91.6% of victims.
- Types of maltreatment:
  - 74.9% neglect
  - 18.3% physical abuse, mother more likely to be perpetrator
  - 7.1% sexual abuse, father more likely to be perpetrator

RISK FACTORS
- American Indian or Alaska Native children had the highest rates of victimization at 14.3 per 1,000 children (1).
- Children in the age group of birth to 1 year had the highest rate of victimization at 25.3 per 1,000 infants (1).
Slightly more than one half of the child victims were girls at 51.0% while 48.6% were boys.
Risk of fatal abuse is more common in those <3 years (71.8% of children who died were <3 years old).
Child risk factors include: chronic illness, physical/congenital disability, developmental disability, preterm, unwanted child/pregnancy
Caregiver risk factors include: poverty, drug abuse, lower educational status, parental history of abuse, parental mental health concerns, young and/or unmarried mother, poor support network, and domestic violence:
  – Child abuse is 4.9 times more likely in family with spouse abuse.
  – Children in households with unrelated adults were 50 times more likely to die of inflicted injuries.
  – Adults who were abused as children are at higher risk of becoming abusers than those who were not abused.

GENERAL PREVENTION
Know your patients and document their family situations; have increased suspicion to screen for risk factors at prenatal, postnatal, and pediatric visits.
Physicians can educate parents on range of normal behaviors to expect in infants and children:
  – Anticipatory guidance on ways to handle crying infants; methods of discipline for toddlers
Train first responders—teachers, childcare workers—to look for signs of abuse and know methods for reporting.
Some studies suggest developing screening tools to identify high-risk families early and offer interventions such as early childhood home visitation programs.

COMMONLY ASSOCIATED CONDITIONS
Failure to thrive
Prematurity
Developmental deficits
Poor school performance
Poor social skills
Low self-esteem, depression

DIAGNOSIS
Relatively minor injuries, frenulum tears, or bruising in precruising infants may be the first indications of child physical abuse; these minor, suspicious injuries have been termed “sentinel injuries”.
In a retrospective study of infants who were definitely abused, 27.5% had a sentinel injury (80% had a bruise), and in 41.9% of those cases, the parent reported that a medical provider was aware of the injury.
Patients may present with seemingly unrelated complaints; multiple studies have documented repeated visits (to the primary care physician, to the emergency department [ED]) before child abuse is suspected.
Infants with injuries caused by child abuse often present with vague complaints; thus, it is important to have high index of suspicion when evaluating infants for fussiness.
Documentation
  – The medical record is an important piece of evidence for investigation and litigation.
Critical elements include the following:
- Brief statement of child’s disclosure or caregiver’s explanation, including any alternate explanations offered
- Time the incident occurred and date/time of disclosure
- Whether witnesses were present
- Developmental abilities of child
- Objective medical findings
- DO NOT use terms such as “rule out,” “R/O,” and “alleged.” They may cause ambiguity; clearly state physician opinion.
- The child should be separated from the parent for the interview if at all possible.
- Any description of abuse given by the child should be recorded word for word using quotation marks in the child’s own language and attributed to the child.
- The child should not be rewarded after a disclosure (e.g., “Tell me what happened and you can go back to your mom . . . ”).
- Remember this is a medical interview and physician is obtaining information needed for diagnostic and treatment decisions.
- Documentation should include disposition of patient and record any report made to CPS.

**HISTORY**
- Use nonjudgmental, open-ended questions (ask: who, what, when, and where; NEVER why).
- Use quotes whenever possible.
- Try to collect one-on-one history from multiple individuals.
- Document past medical history, developmental history, child’s temperament, and thorough social history including family interactions.
- History of a sentinel injury should prompt consideration of abuse; it may be the first and only abusive injury; there may be escalating and repeated violence instead of a single event of momentary loss of control.
- The following are suggestive of intentional trauma:
  - No explanation or vague explanation of injury.
  - Important detail of explanation changes dramatically.
  - Explanation is inconsistent with pattern, age, or severity.
  - Explanation is inconsistent with child’s physical or developmental abilities.
  - Different witnesses provide different history.
  - Considerable delay in seeking treatment.
  - Denial of trauma in a child with injury.
- Nonspecific symptoms of abuse:
  - Behavior changes; self-destructive behavior
  - Anxiety and/or depression
  - Sleep disturbances, night terrors
  - School problems

**PHYSICAL EXAM**
- Examine child in a comfortable setting:
  - Explain what the exam will involve and why procedures are needed.
  - Allow child to choose who will be in the room.
  - Use appropriate positions to examine the anal and genital areas of children.
- Complete a general assessment for signs of physical abuse, neglect, and self-injurious
behaviors:
– Maintain high index of suspicion when occult head, chest, and abdominal trauma are present.
– Measurements, photographs, and careful descriptions are critical for accurate diagnosis.
– Encourage collaboration with specialist and child abuse assessment team.

A thorough physical exam may include:
– Skin
– Head (including fontanels), eyes, ears, nose, and mouth
– Chest/abdomen
– Genital (consider exam under sedation) or refer to ED
– Extremities, with focus on inner arms, inner legs, palms, and soles
– Growth data

Physical abuse
– Skin markings (e.g., lacerations, burns, ecchymoses, linear/shaped contusions, bites)
– Immersion injuries with clearly distinguished outlines (e.g., from boiling water)
– Oral trauma (e.g., torn frenulum, loose teeth)
– Ear trauma (e.g., signs of ear pulling)
– Eye trauma (e.g., hyphema, hemorrhage)
– Head/abdominal blunt trauma
– Fractures

Sexual abuse
– Unexplained penile, vaginal, hymenal, perianal, or anal injuries/bleeding/discharge
– Pregnancy or sexually transmitted infections (STIs)
– Sperm is a definitive finding of child abuse.

Neglect
– Low weight for height, unclean, unkempt
– Rashes
– Fearful or too trusting
– Clinging to or avoiding caregiver
– Flat or balding occiput
– Abnormal development or growth parameters

DIFFERENTIAL DIAGNOSIS

Physical trauma
– Accidental injury; toxic ingestion
– Bleeding disorders (e.g., classic hemophilia)
– Metabolic or congenital conditions
– Conditions with skin manifestations (e.g., mongolian spots, Henoch-Schönlein purpura, meningococcemia, erythema multiforme, hypersensitivity, car seat burns, staphylococcal scalded skin syndrome, chickenpox, impetigo)
– Cultural practices (e.g., cupping, coining)

Neglect
– Endocrinopathies (e.g., diabetes mellitus)
– Constitutional
– GI (clefts, malabsorption, irritable bowel)
– Seizure disorder
– Sudden infant death syndrome (SIDS)
- Skeletal trauma
  - Obstetrical trauma
  - Nutritional (scurvy, rickets)
  - Infection (congenital syphilis, osteomyelitis)
  - Osteogenesis imperfecta

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Directed by history and physical exam:
  - Urinalysis (abdominal/flank/back/genital trauma), urine DNA probe for STIs
  - Complete blood count, coagulation studies
  - Electrolytes, creatinine, blood urea nitrogen, glucose
  - Liver and pancreatic function tests (abdominal trauma)
  - Guaiac stool (abdominal trauma)

- In cases of suspected neglect:
  - Stool exam, calorie count, purified protein derivative and anergy panel, sweat test, lead and zinc levels

- In cases of suspected sexual abuse:
  - STI testing: gonorrhea, chlamydia, Trichomonas; also consider HIV, herpes simplex virus (HSV), hepatitis panel, syphilis.
  - The American Academy of Pediatrics (AAP) recommends the use of NAATs when evaluating children and adolescents for Chlamydia trachomatis and Neisseria gonorrhoeae.
  - Serum pregnancy test

- Skeletal survey is a mainstay of child abuse evaluation; 22 radiographs.
  - It is recommended for:
    - Infants <6 months with bruising, regardless of pattern (given rarity of accidental bruising in young nonmobile infants)
    - Children with bruising attributed to abuse or domestic violence
    - Children <12 months with bruising on the cheek, eye area, ear, neck, upper arm, upper leg, hand, foot, torso, buttocks, or genital area
    - All children with fractures and suspicious injuries <2 years old, consider bone scan for rib fractures and long bone fractures.
  - Suspected intracranial and extracranial injury:
    - Computed tomography (CT) scan of head
    - Consider magnetic resonance imaging of head/neck, looking at subtle findings, intercerebral edema, or hemorrhage.
  - Intra-abdominal injuries: CT scan of abdomen

- High risk imaging findings:
  - Spiral fractures in nonambulatory patients (Children who are not walking or cruising should not have bruising or fractures from “falls.”)
  - Chip or bucket-handle fractures
  - Epiphyseal/metaphyseal rib fractures in infants
  - Rupture of liver/spleen in abdominal blunt trauma

**Follow-Up Tests & Special Considerations**

- Red flags
  - History that is inconsistent with the injury
– No explanation offered for the injury or injury blamed on sibling or another child
– History that is inconsistent with the child’s developmental level
• Maintain a high level of suspicion when exam findings indicate multiple types of injury.
• Recent literature notes a greater risk of abuse with skull and femur fractures, unexplained injuries, and a delay in seeking care.
– Patterns suggestive of abuse
  o Bruises seen away from bony prominences
  o Bruises to face, back, abdomen, arms, buttocks, ears, hands
  o Multiple bruises in clusters or uniform shape
  o Patterned injuries (such as bite marks or the imprint of an object like a belt or cord) should be considered inflicted until proven otherwise.
– TEN-4 method to identify bruises suggestive of child abuse:
  o T: torso
  o E: ear
  o N: neck
  o 4: 4 or more bruises in a child under 4 years old, or any bruise in a child under 4 months old
• Bruising is a common presenting feature:
  – Retinal hemorrhage is a red flag that should trigger consideration for shaken baby syndrome
  – Sexual abuse
    o Consider whether child should be triaged to facility such as children’s hospital where collection of forensic samples can be performed.

**TREATMENT**

**GENERAL MEASURES**
If HIV exposure possible, consider prophylaxis.

**MEDICATION**

**First Line**
Antibiotics as indicated for STIs

**ALERT**
Emergency contraception reduces rate of pregnancy after sexual assault:

• Levonorgestrel (Plan B): single dose of 1.5 mg or two 0.75-mg doses taken together or 12 hours apart; effective up to 72 hours
• Ulipristal (Ella): 30-mg single dose as soon as possible; effective up to 120 hours

**ISSUES FOR REFERRAL**
When responding to possible abuse, consider:

• The child’s safety. Is the child at imminent risk for additional harm if sent back to the environment where the possible perpetrator has access to the child?
• Child’s mental health.
• The need for a physical exam and for forensic collection. Consider referral to the emergency department
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admission if:
- Moderate to severe injuries or unstable
- Acute psychological trauma
- Safety of child cannot be guaranteed

ONGOING CARE

PROGNOSIS
Without intervention, child abuse is often a chronic and escalating phenomenon.

COMPLICATIONS
Sexual, physical, and emotional abuse in childhood are risk factors for poorer adult mental and physical health; includes maltreatment and depressive disorder, drug use, suicide attempts, and risky sexual behaviors

REFERENCES

CODES

ICD10
- T74.12XA Child physical abuse, confirmed, initial encounter
- T74.32XA Child psychological abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter

CLINICAL PEARLS
- When a bruise is present, it should be considered as potentially sentinel for physical abuse if no plausible explanation is given.
- High index of suspicion is important for prevention and recognition of abuse. Vague complaints and repeated visits to the office and/or ED should prompt further investigation.
- Neglect is the most common and lethal form of abuse and should be aggressively reported.
- Detailed exam with documentation is key.
- Mandated reporting is required for suspected child abuse and neglect; the physician does not have to prove abuse before reporting.
- National hotline: 800.4.A.CHILD (800.422.4453)
- National resources: https://www.childwelfare.gov/pubs/reslist/tollfree/
CHLAMYDIA INFECTION (SEXUALLY TRANSMITTED)
Casandra Cashman, MD, FAAFP

BASICS

DESCRIPTION
- Chlamydia trachomatis is an intracellular membrane-bound prokaryotic organism. Chlamydia derives from the Greek word for “cloak.”
- Chlamydia is the most common bacterial sexually transmitted infection (STI) in the United States.
- Transmitted through vaginal, anal, or oral sex; transmitted vertically during vaginal delivery
- Most cases are asymptomatic, especially in females. Untreated disease can lead to pelvic inflammatory disease (PID), ectopic pregnancy, and infertility.
- System(s) affected: reproductive

Pregnancy Considerations
Perinatal acquisition may result in neonatal pneumonia and/or conjunctivitis.

EPIDEMIOLOGY

Incidence
- Mandatory reporting started in 1985; there has generally been a steady increase in incidence since.
- ~1.7 million reported cases in 2017 (most recent data available from CDC). Increasing incidence reflects broader screening, improved testing, and better reporting (rather than a large increase in disease burden).
- Swedish new variant of C. trachomatis (nvCT) first reported in 2006; often produces false-negative tests; largely confined to Nordic countries

Prevalence
- 528/100,000 people in the United States
- Young females, ethnic minorities most affected
- Highest prevalence ages 20 to 24 years
- Predominant sex: females > males. Females have 2 times higher reported incidence and prevalence than males. This likely reflects increased testing in females. Increasing use of highly sensitive nucleic acid amplification test (NAAT) urine screening may increase identification in males.
- Infection rates ~6 times higher in blacks than whites. Rates are higher in larger urban areas.
- Highest male prevalence in heterosexual adolescents
- Estimated to affect ~2% of young sexually active individuals in the United States

ETIOLOGY AND PATHOPHYSIOLOGY
C. trachomatis serotypes D to K associated with genital tract infections. Chlamydia is an obligate intracellular organism. Chlamydia has biphasic life cycle. Exists extracellularly as elementary body (EB) that is metabolically inactive and infectious. Once taken up by host cell (typically columnar epithelium of the genital tract), the EB prevents lysosomal phagocytosis and transforms to reticulate body (RB), which requires energy from host cell to synthesize RNA,
DNA, and proteins. After taking up host cell residence, EB are released and are capable of infecting neighboring cells or spreading the infection through sexual contact.

**RISK FACTORS**
Risk correlates with:
- Number of lifetime sexual partners and number of concurrent sexual partners
- No use of barrier contraception during intercourse
- Black/Hispanic/Native American and Alaskan Native ethnicity
- Men who have sex with men (MSM) may be at higher risk for rectal and pharyngeal chlamydia than other groups; consider testing with NAAT when appropriate (1).

**GENERAL PREVENTION**
- Screen populations with prevalence >5% at least annually.
- Screening recommended if new or >1 sex partner in past 6 months; attending an adolescent clinic, family planning clinic, STD or abortion clinic, or attending a jail or other detention center clinic. Screen for rectal pain, discharge or tenesmus, testicular pain; test all individuals with urethral or cervical discharge.
- All sexually active women ≤25 years of age should be screened at least yearly. Repeat testing in ~3 months is recommended for those who screen positive because reinfection rate is high regardless of whether the sexual partner is treated (2)[A].
- Consider screening sexually active men ≤25 years of age particularly in high-risk populations.
- Screen high-risk MSM annually with genital and extragenital screening (3)[A].
- NAAT is the preferred screening test in all circumstances except child sexual abuse involving boys or rectal/oropharyngeal testing in prepubescent girls. For these situations, culture and susceptibility testing is preferred (3)[A].
- Acceptable to screen women for chlamydia on same day as intrauterine device (IUD) insertion—treat if positive (no need to remove IUD in this circumstance) (4)[B]

**COMMONLY ASSOCIATED CONDITIONS**
- **Females**
  - PID: ~10% develop PID within 12 months if untreated.
  - Infertility, ectopic pregnancy
  - Chronic pelvic pain
  - Urethral syndrome (dysuria, frequency, and pyuria in the absence of infection)
  - Arthritis (less common)
  - Spontaneous abortion
- **Males**
  - Epididymitis and nongonococcal urethritis
  - Reiter syndrome (HLA-B27)
  - Proctitis
- **Neonates**
  - Inclusion conjunctivitis (occurs in ~40% of exposed neonates)
  - Otitis media
  - Pneumonia
  - Pharyngitis
- **Diseases caused by other chlamydial species**
  - Lymphogranuloma venereum (LGV): C. trachomatis serotypes L1 to L3
– Trachoma: C. trachomatis serotypes A to C

DIAGNOSIS

Many patients are asymptomatic.

Pregnancy Considerations

- Test all patients at first prenatal visit.
- Obtain repeat testing 3 to 4 weeks after treatment for all pregnant patients with confirmed chlamydial infection. Test again 3 months after.
- Repeat screening in 3rd trimester in high-risk patients.[A]

HISTORY

- Complete sexual history, including number of sex partners (lifetime and past year), prior history of STIs, use of barrier protection, commercial sex work, oral or anal receptive intercourse, and partner fidelity
- In females, the most common symptoms are:
  - Mucopurulent vaginal discharge, dysuria (urethral syndrome), Bartholinitis, abdominopelvic pain (endometritis, salpingitis/PID), right upper quadrant pain (Fitz-Hugh–Curtis syndrome)
- In males, the most common symptoms are:
  - Dysuria, urethral discharge (urethritis), scrotal pain (epididymitis), rectal pain or discharge (proctitis), acute arthritis (Reiter syndrome)

PHYSICAL EXAM

- Men and women: external genitalia (rash, lesions), urethral discharge, inguinal lymphadenopathy, pharyngeal exudate, and perianal lesions
- Women: cervix (discharge, motion tenderness), bimanual examination for cervical motion tenderness, uterine, ovarian/adnexal tenderness or mass
- LGV (C. trachomatis serovars L1, L2, or L3): Primary lesion is a small papule that may ulcerate at the site of transmission after an incubation period of 3 to 30 days. Unilateral tender lymphadenopathy. With rectal transmission, LGV causes an invasive proctocolitis.

DIFFERENTIAL DIAGNOSIS

- Neisseria gonorrhoeae: urethritis, proctitis, epididymitis, cervicitis, PID, Bartholin abscess
- Mycoplasma or Ureaplasma urealyticum: urethritis, epididymitis, Reiter disease, PID
- C. trachomatis (serotypes L1 to L3): LGV, proctitis
- Trichomoniasis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- NAAT: sensitivity >95%; specificity >99%
- Urine test is similarly sensitive to cervical swabs, but preferably is collected on first catch urine. Self-collected vaginal swabs are most sensitive.[3]
- Lab result may remain positive for 3 weeks after successful treatment.
- Test for concurrent STIs, including gonorrhea, HIV, and syphilis; perform cervical cancer (Pap smear) screening according to recommended guidelines.

Follow-Up Tests & Special Considerations
GENERAL MEASURES

- Offer patients concurrent testing for gonorrhea, HIV (after counseling and consent), and possibly syphilis. Ensure women are up to date with recommended cervical cancer screening.
- Consider treating gonorrhea empirically.
- Test and treat all partners (most recent partner and all partners within the past 60 days).

MEDICATION

First Line

- Treatment of chlamydial urethritis, cervicitis (including sexual partners of infected persons)
- Azithromycin 1 g PO single dose or
- Doxycycline 100 mg PO BID for 7 days
- First-line PID treatment (outpatient)
  - Ceftriaxone 250 mg IM × 1 plus doxycycline 100 mg PO for 14 days with or without metronidazole 500 mg PO BID for 14 days or
  - Cefoxitin 2 g IM × 1 with probenecid 1 g PO × 1 plus doxycycline 100 mg PO for 14 days with or without metronidazole 500 mg PO BID for 14 days
- Azithromycin and ceftriaxone may be given simultaneously in the office to treat both chlamydia and gonorrhea. This reduces nonadherence.

Asymptomatic rectal chlamydia can be treated with doxycycline 100 mg BID × 7 days. Azithromycin 1 g for 1 day is slightly less effective but can also be used, especially if compliance or medication availability is an issue (5)[A].

ALERT

Use azithromycin with caution in patients with known QT prolongation, hypokalemia, hypomagnesemia, bradycardia, or who are currently treated with antiarrhythmics.

Pregnancy Considerations

- Tetracyclines (doxycycline) and quinolones (ofloxacin, levofloxacin) are contraindicated in pregnant women.
- Consider the following:
  - Azithromycin 1 g PO or
  - Amoxicillin 500 mg PO TID for 7 days (2)[A] or
  - Erythromycin base 500 mg PO QID for 7 days

ALERT

Tetracyclines and quinolones are contraindicated in young children:

- <45 kg: erythromycin base or ethinyl succinate 500 mg/kg/day PO QID for 14 days
- >45 kg but <8 years: azithromycin 1 g PO once
- >8 years: adult regimen
- Rule out sexual abuse in children with chlamydial infections.

Second Line
For chlamydial urethritis/cervicitis

- Erythromycin base 500 mg PO QID for 7 days OR erythromycin ethylsuccinate 800 mg PO QID for 7 days
- Levofloxacin 500 mg PO daily for 7 days or ofloxacin 300 mg PO BID for 7 days

ADDITIONAL THERAPIES

Patient-delivered partner therapy (PDPT) or expedited partner therapy (EPT): Provide medications or prescriptions to take to sexual partners of persons infected with STIs without clinical assessment.

- EPT reduces recurrence more effectively than traditional partner referral.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient treatment of PID: pregnancy, lack of response or intolerance to oral medicines, suspicion of poor compliance, severe clinical illness, pelvic abscess, and possible need for surgical intervention
- Otherwise, treat PID as outpatient unless moderately or severely ill.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Abstain from sexual contact for at least 7 days after treatment (single-dose treatment) or until completion of the full course of other antibiotics.

Patient Monitoring

- Test of cure not routinely recommended except in pregnancy. Do not repeat NAAT <3 weeks after testing; may be falsely positive due to nonviable organisms
- Test of cure in 3 to 4 weeks in pregnancy as well as test for reinfection in 3 months.
- Consider rescreening higher risk pregnant women in 3rd trimester even if initial screening negative.
- Test for reinfection (not cure) 3 months after treatment or, if not possible, then at next presentation to medical care if within 12 months.
- Sexual partners should be treated. Some states allow for expedited partner therapy.

PATIENT EDUCATION

- Counsel regarding safe sexual practices, barrier protection, and abstinence.
- Complete antibiotic course (patient and partners).

PROGNOSIS

Prognosis is good following therapy.

COMPLICATIONS

- Both sexes: Chlamydial infection enhances transmission of and susceptibility to HIV.
- Females: tubal infertility (most common cause of acquired infertility), tubal (ectopic) pregnancy, chronic pelvic pain
  - Annual screening of sexually active women would prevent 61% of chlamydia-related PID.
- Males: transient oligospermia and postepididymitis urethral stricture (rare)
REFERENCES

ADDITIONAL READING

SEE ALSO

Cervicitis, Ectropion, and True Erosion; Epididymitis; Gonococcal Infections; HIV/AIDS; Pelvic Inflammatory Disease (PID); Syphilis; Urethritis

CODES

ICD10
- A56.8 Sexually transmitted chlamydial infection of other sites
- A56.01 Chlamydial cystitis and urethritis
- A56.02 Chlamydial vulvovaginitis

CLINICAL PEARLS

- C. trachomatis is common in young sexually active individuals. Annual screening is recommended in sexually active women 25 years of age and younger and in other individuals with known risk factors.
- To prevent recurrence, treat patients and their partners concurrently.
- Test of cure is only recommended for pregnant patients 3 to 4 weeks after treatment for an
identified Chlamydia infection. Test for reinfection 3 months afterward. Repeat screens in 3rd trimester for high-risk patients regardless of initial test results.
CHOLELITHIASIS
Hongyi Cui, MD, PhD

BASICS

DESCRIPTION
- The presence of cholesterol, pigment, or mixed stones (calculi) within the gallbladder
- Synonym(s): gallstones

Pediatric Considerations
- Uncommon in children ≤10 years
- Most gallstones in children are pigment stones associated with blood dyscrasias.

EPIDEMIOLOGY

Incidence
- Increased in Native Americans and Hispanics
- Increases with age ~1–3% per year; peaks at 7th decade
- 2% of the U.S. population develops gallstones annually.

Prevalence
- 8–10% of the U.S. population with gallstones
- 20% >65 years of age
- Female > male (2 to 3:1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Gallstone formation is a complex process mediated by genetic, metabolic, immune, and environmental factors. Gallbladder sludge (a mixture of cholesterol crystals, calcium bilirubinate granules, and mucin gel matrix) serves as the nidus for gallstone formation.
- Bile supersaturated with cholesterol (cholesterol stones) precipitates as microcrystals that aggregate and expand. Stone formation is enhanced by biliary stasis or impaired gallbladder motility.
- Decrease in bile phospholipid (lecithin) or decreased bile salt secretion
- Excess unconjugated bilirubin in patients with hemolytic diseases; passage of excess bile salt into the colon with subsequent absorption of excess unconjugated bilirubin in patients with inflammatory bowel disease (IBD) or after distal ileal resection (black or pigment stones)
- Hydrolysis of conjugated bilirubin or phospholipid by bacteria in patients with biliary tract infection or stricture (brown stones or primary bile duct stones; rare in the Western world and common in Asia)

RISK FACTORS
- Age peaks in patients 60 to 80 years of age.
- Female gender, pregnancy, multiparity, obesity, and metabolic syndrome
- Caucasian, Hispanic, or Native American descent
- High-fat diet rich in cholesterol
- Cholestasis or impaired gallbladder motility in association with prolonged fasting, long-term total parenteral nutrition (TPN), following vagotomy, long-term somatostatin therapy, and
rapid weight loss
- Hereditary (p.D19H variant for the hepatic canalicular cholesterol transporter ABCG5/ABG8)
- Short gut syndrome, terminal ileal resection, IBD
- Hemolytic disorders (hereditary spherocytosis, sickle cell anemia, etc.), cirrhosis (black/pigment stones)
- Medications (birth control pills, estrogen replacement therapy at high doses, and long-term corticosteroid or cytostatic therapy)
- Viral hepatitis, biliary tract infection, and stricture (promotes intraductal formation of pigment stones)

GENERAL PREVENTION
- Ursodiol (Actigall) taken during rapid weight loss prevents gallstone formation.
- Regular exercise and dietary modification may reduce the incidence of gallstone formation.
- Lipid-lowering drugs (statins) may prevent cholesterol stone formation by reducing bile cholesterol saturation.

COMMONLY ASSOCIATED CONDITIONS
- 90% of people with gallbladder carcinoma have gallstones and chronic cholecystitis.

DIAGNOSIS

HISTORY
- Mostly asymptomatic (80%): 2% become symptomatic each year. Over their lifetime, <50% of patients with gallstones develop symptoms.
- Episodic right upper quadrant or epigastric pain lasting >15 minutes and sometimes radiating to the back (biliary colic—due to transient cystic duct obstruction)
- Pain is usually postprandial.
- Pain sometimes awakens patients from sleep.
- Most patients develop recurrent symptoms after a first episode of biliary colic.
- Other symptoms include nausea, vomiting, indigestion or bloating sensation, and fatty food intolerance.

PHYSICAL EXAM
- Physical exam is usually normal in patients with cholelithiasis in the absence of an acute attack.
- Epigastric and/or right upper quadrant tenderness (Murphy sign) is a traditional physical finding associated with acute cholecystitis. Murphy sign has limited sensitivity and specificity.
- Charcot triad: fever, jaundice, right upper quadrant pain historically associated with cholangitis
- Reynolds pentad: fever, jaundice, right upper quadrant pain, hemodynamic instability, mental status changes; also classically associated with ascending cholangitis
- Flank and periumbilical ecchymoses (Cullen sign and Grey Turner sign) in patients with acute hemorrhagic pancreatitis
- Courvoisier sign: palpable mass in the right upper quadrant in patient with obstructive jaundice most commonly due to malignant tumors within the biliary tree or pancreas

DIFFERENTIAL DIAGNOSIS
- Peptic ulcer diseases and gastritis
Hepatitis  
Pancreatitis  
Cholangitis  
Gallbladder cancer  
Gallbladder polyps  
Acalculous cholecystitis  
Biliary dyskinesia  
Choledocholithiasis

DIAGNOSTIC TESTS & INTERPRETATION
Ultrasound is the preferred diagnostic modality for cholelithiasis.

Initial Tests (lab, imaging)
- Leukocytosis and elevated C-reactive protein level are associated with acute calculus cholecystitis.
- Ultrasound (US) is the preferred imaging modality. US detects gallstones in 97–98% of patients.
- Thickening of the gallbladder wall (≥5 mm), pericholecystic fluid, and direct tenderness when the probe is pushed against the gallbladder (sonographic Murphy sign) are associated with acute cholecystitis.
- CT scan has no advantage over US except for detecting distal common bile duct (CBD) stones.
- MR cholangiopancreatography (MRCP) is reserved for cases of suspected CBD stones. However, MRCP has no therapeutic value, and preoperative MRCP is not more cost-effective than initial cholecystectomy with cholangiography in the diagnosis of patients with suspected CBD stones and patients with mild to moderate gallstone pancreatitis (GP).
- Endoscopic US is as sensitive as endoscopic retrograde cholangiopancreatography (ERCP) for detection of CBD stones in patients with GP.
- Hepatobiliary iminodiacetic acid (HIDA) scan is useful in diagnosing acute cholecystitis secondary to cystic duct obstruction. It is also useful in differentiating acalculous cholecystitis from other causes of abdominal pain. False-positive tests can result from a fasting state, insufficient resistance of the sphincter of Oddi, and gallbladder agenesis.
- Cholecystokinin (CCK)-HIDA is specifically used to diagnose gallbladder dysmotility (biliary dyskinesia).
- 10–30% of gallstones are radiopaque calcium or pigment-containing gallstones (visible on plain x-ray). A “porcelain gallbladder” is a calcified gallbladder (also visible by x-ray) that is associated with chronic cholecystitis and gallbladder cancer.

Test Interpretation
- Pure cholesterol stones are white or slightly yellow.
- Pigment stones may be black or brown. Black stones contain polymerized calcium bilirubinate, most often secondary to cirrhosis or hemolysis; these almost always form within the gallbladder.
- Brown stones are associated with biliary tract infection, caused by bile stasis, and as such may form either in the bile ducts or gallbladder.

TREATMENT
GENERAL MEASURES

- Treat symptomatic cholelithiasis.
- Conservative therapy is preferred during pregnancy; surgery in the 2nd trimester if necessary.
- Prophylactic cholecystectomy for patients with calcified (porcelain) gallbladder (risk for gallbladder cancer), patients with large stones (≥3 cm), patients with sickle cell disease, patients planning an organ transplant, and patients with recurrent pancreatitis due to microlithias.
- In morbidly obese patients, cholecystectomy may be performed in combination with bariatric procedures to reduce subsequent stone-related comorbidities.
- Prophylactic cholecystectomy is recommended for gallstones discovered incidentally during open abdominal surgery.

Geriatric Considerations
Gallstones are more common in the elderly. Age alone should not alter the therapeutic plan.

MEDICATION

First Line

- Analgesics for pain relief
  - Nonsteroidal anti-inflammatory drugs (NSAIDs) are the first-choice treatment for pain control which is equivalent to opioid therapy.
  - Opioids are an option for patients who cannot tolerate or fail to respond to NSAIDs.

- Antibiotics for patients with acute cholecystitis

Prophylactic antibiotics in low-risk patients do not prevent infections during laparoscopic cholecystectomy (LC) (1)[A].

ISSUES FOR REFERRAL

Patients with retained or recurrent bile duct stones following cholecystectomy should be referred for ERCP.

SURGERY/OTHER PROCEDURES

- Surgery should be considered for patients who have symptomatic cholelithiasis or gallstone-related complications (e.g., cholecystitis) or in asymptomatic patients with immune suppression, calcified gallbladder, or family history of gallbladder cancer.
- Open and LC have similar mortality and complication rates. LC offers less pain and quicker recovery and is the current gold-standard treatment.
- In well-selected patients, single-incision LC (SILC) and robotic LC are treatments for symptomatic cholelithiasis. SILC has not been shown to be superior to conventional multiport LC in terms of pain and risk of complication. Natural orifice transluminal endoscopic surgery (NOTES) is investigational. Surgery-related complications include CBD injury (0.2%), right hepatic duct/artery injury, retained stones, duct leak, biloma formation, and bile duct stricture. Bile spillage during LC has been shown to be a risk factor for surgical site infection.
  - Conversion to open procedure is based on clinical judgment. Male gender, previous upper abdominal surgery, thickened gallbladder wall, and acute cholecystitis increase the likelihood of need to convert to an open procedure.
  - In 10–15% of patients with symptomatic cholelithiasis, CBD stones are detected by intraoperative cholangiogram (IOC). CBD stone(s) can be removed by laparoscopic CBD exploration or postoperative ERCP.
IOC helps delineate bile duct anatomy when dissection is difficult. Routine use of IOC is controversial and may be associated with decreased incidence and severity of bile duct injury.

- Early LC (<24 hours after diagnosis of biliary colic) decreases hospital stay and operating time (2)[A].
- For patients with acute cholecystitis, early LC (<7 days of clinical presentation) is safe and may shorten the total hospital stay versus delayed LC (>6 weeks after index admission with acute cholecystitis) (3)[A]
- Laparoscopic partial/subtotal cholecystectomy is a viable option in difficult operative condition (such as severe cholecystitis).
- Percutaneous cholecystostomy (PC) is used for high-risk patients with cholecystitis or gallbladder empyema. Interval cholecystectomy is recommended.
- Symptomatic patients who are not candidates for surgery or those who have small gallstones (5 mm or smaller) in a functioning gallbladder with a patent cystic duct are candidates for oral dissolution therapy (ursodiol [Actigall]). The recurrence rate is >50% once medication is discontinued.
- Extracorporeal shock wave lithotripsy is a noninvasive therapeutic alternative for symptomatic patients who are not candidates for surgery. It helps break down large bile duct stones before ERCP. Complications include biliary pancreatitis, hepatic hematoma, incomplete ductal stone clearance, and recurrence.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
For patients with symptomatic cholelithiasis, LC is typically an outpatient procedure. For patients with complications (i.e., cholecystitis, cholangitis, pancreatitis), inpatient care is necessary.
- Acute phase: NPO, IV fluids, and antibiotics
- Adequate pain control with narcotics and/or NSAIDs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow for signs of symptomatic cholelithiasis.
- Follow patients on oral dissolution agents with serial liver enzymes, serum cholesterol, and imaging.

DIET
A low-fat diet may help.

PATIENT EDUCATION
- Change in lifestyle (e.g., regular exercise) and dietary modification (low-fat diet and reduction of total caloric intake) reduce gallstone-related hospitalizations.
- Patients with asymptomatic gallstones should be educated about the typical symptoms of biliary colic and gallstone-related complications.

PROGNOSIS
<50% of patients with gallstones become symptomatic.

Cholecystectomy-related mortality is <0.5% in elective cases and 3–5% in emergency cases; morbidity is <10% in elective cases and 30–40% in emergency cases.

~10–15% of patients have associated choledocholithiasis.

After cholecystectomy, stones may recur within the biliary tree in patients with associated risk factors.

**COMPLICATIONS**

- Acute cholecystitis (90–95% secondary to gallstones)
- GP; ERCP ±; sphincterotomy of no clear benefit in patients with mild GP but reduces complications in those with severe GP (4)[A]
- CBD stones with obstructive jaundice and acute cholangitis. In patients undergoing ERCP for CBD stones, early LC reduces the risk of recurrent biliary events (5)[B].
- Biliary-enteric fistula and gallstone ileus
- Bouveret syndrome is a variant of gallstone ileus where the gallstone lodges in the duodenum or pylorus causing a gastric outlet obstruction.
- Gallbladder cancer
- Mirizzi syndrome (extrinsic bile duct obstruction caused by gallstones lodged in gallbladder or cystic duct)

SEE ALSO
Cholangitis, Acute; Choledocholithiasis

CODES
ICD10
K80.20 Calculus of gallbladder w/o cholecystitis w/o obstruction
K80.21 Calculus of gallbladder w/o cholecystitis with obstruction
K80.01 Calculus of gallbladder w acute cholecystitis w obstruction

CLINICAL PEARLS
- Most patients with gallstones are asymptomatic.
- Transabdominal US is the imaging modality of choice for the diagnosis of cholelithiasis (sensitivity, 97%; specificity, 95%).
- Laparoscopic cholecystectomy is the preferred surgical procedure for symptomatic cholelithiasis.
- Acute acalculous cholecystitis is associated with bile stasis and gallbladder ischemia.
- Prophylactic cholecystectomy is not indicated in patients with asymptomatic gallstones.
CHRONIC COUGH
Jacqueline L. Olin, MS, PharmD, BCPS, CDE, FASHP, FCCP
Brian Hertz, MD
J. Andrew Woods, PharmD, BCPS

BASICS

DESCRIPTION
- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In children, chronic cough is often defined as a cough of >4 weeks in duration.
- Subacute cough describes a cough lasting 3 to 8 weeks.
- Patients present because of fear of the causative illness (e.g., cancer), annoyance, self-consciousness, and hoarseness.
- System(s) affected: gastrointestinal (GI), pulmonary

EPIDEMIOLOGY
- Predominant age: all age groups
- Predominant sex: male = female, with females more likely to seek out medical attention

Incidence
Persistent unexplained cough occurs in up to 10% of patients presenting with chronic cough and up to 46% referred to specialty cough clinics (1).

Prevalence
Chronic cough is one of the most common reasons for primary care visits.

ETIOLOGY AND PATHOPHYSIOLOGY
Varies with findings and disorders implicated
- Often multiple etiologies, but most are related to bronchial irritation. Frequent etiologies (account for >90% of cases) in nonsmokers include the following:
  - Upper airway cough syndrome (UACS) and other upper airway abnormalities, including allergic and vasomotor rhinitis syndromes
  - Chronic rhinitis with postnasal drip (allergic, nonallergic, chronic sinusitis, etc.)
  - Postviral cough
  - Asthma
  - Gastroesophageal reflux disease (GERD)
- Other causes:
  - ACE inhibitors
  - Chronic smoking or exposure to smoke or pollutants
  - Aspiration
  - Bronchiectasis
  - Infections (e.g., pertussis, tuberculosis)
  - Nonasthmatic eosinophilic bronchitis (NAEB)
  - Cystic fibrosis
  - Sleep apnea
  - Restrictive lung diseases
  - Neoplasms: bronchogenic or laryngeal
Psychogenic (habit cough)

- Cough hypersensitivity syndrome defines a syndrome of cough with characteristic trigger symptoms not adequately explained by other medical conditions.
- Etiologies of chronic cough in young children differ from those in older children and adults with asthma, protracted bacterial bronchitis, and UACS as most common causes (2,3).

RISK FACTORS
Although various conditions may contribute to chronic cough, the main causes include smoking and pulmonary diseases.

COMMONLY ASSOCIATED CONDITIONS
Patients with UACS, asthma, and GERD may present with chronic cough as the only symptom and not the usual symptoms associated with the diagnoses.

DIAGNOSIS

HISTORY
- Patient’s age, associated signs/symptoms, medical history, medication history (i.e., ACE inhibitors), environmental and occupational exposures, potential for aspiration, and smoking history may make some causes more likely.
- The character of cough or description of sputum quality is rarely helpful in predicting the underlying cause.
- Cough diaries have not correlated well with objective measures.
- Hemoptysis or signs of systemic illness preclude empiric therapy.

PHYSICAL EXAM
- Signs and symptoms are variable and related to the underlying cause; usually, a nonproductive cough with no other signs or symptoms
- Possible signs and symptoms of UACS, sinusitis, GERD, congestive heart failure, chronic stressors
- Absence of additional signs/symptoms of a particular condition not necessarily helpful
  - For example, 5% of patients with GERD have no other signs or symptoms and sometimes have poor response to empiric proton pump inhibitor (PPI) trials.

DIAGNOSTIC TESTS & INTERPRETATION
- Evaluation often starts with empiric therapy directed at likely underlying etiology and/or simple testing such as a chest x-ray (CXR).
- Extensive testing only if indicated by the history and physical

Pediatric Considerations
Children with chronic cough not responsive to an inhaled β-agonist and without overt stressors should undergo spirometry (if age-appropriate) and foreign body evaluation (CXR).

Initial Tests (lab, imaging)
- Evaluation will be dictated by findings in the comprehensive history and physical.
- Evaluation of peak flow may be indicated.
- If considering neoplasm, heart failure, or infectious etiologies, CXR or B-type natriuretic peptide (BNP) may be indicated.
In cases of failure to respond to initial trial of empiric therapy, CXR may also be beneficial.

**Follow-Up Tests & Special Considerations**

- **Examples:**
  - If considering chronic obstructive pulmonary disease (COPD), asthma, or restrictive lung disease: spirometry
  - If suspicious of cystic fibrosis: sweat chloride testing
  - If suspicious of hypereosinophilic syndrome, tuberculosis, or malignancy: sputum for eosinophils and cytology
- If abnormal CXR, suspected neoplasm, or underlying pulmonary disorder, consider a chest CT.
- Consider pulmonary consultation.
- Consider specialist cough clinic.
- Refer to gastroenterologist for endoscopy.

**Diagnostic Procedures/Other**

If diagnosis suggested and inadequate response to initial measures, other procedures can be considered:

- Pulmonary function testing
- Purified protein derivative (PPD) skin testing
- Allergen testing
- 24-hour esophageal pH monitor
- Bronchoscopy, if history of hemoptysis or smoking with normal CXR
- Endoscopic or video fluoroscopic swallow evaluation or barium esophagram
- Sinus CT
- Ambulatory cough monitoring and cough challenge with citric acid, capsaicin, or other bronchodilator (at specialized cough clinic)
- Echocardiogram

**Test Interpretation**

Specific to underlying cause

---

**TREATMENT**

**GENERAL MEASURES**

- With chronic cough, empiric treatment should be directed at the most common causes as clinically indicated (UACS, asthma, GERD) (1,3)[C].
- Empiric trial of nasal steroids and/or antihistamines should be considered if allergic symptoms or postnasal drip is present.
- With concomitant complaints of heartburn and regurgitation, GERD should be considered as a potential etiology (3)[C].
- In patients with cough associated with the common cold, nonsedating antihistamines were not found to be effective in reducing cough (1,3)[C]. Many patients will have resolution of cough after smoking cessation.
- When indicated, ACE inhibitor therapy should be switched in patients in whom intolerable cough occurs. It may take several days or weeks for cough to resolve after stopping ACE inhibitor therapy.
- Empirically treat postnasal drip and GERD.
Empiric PPI are not recommended in children or adults in the absence of a GERD diagnosis (3)[C].

Multimodality speech pathology therapy had a positive benefit on cough severity in some adults (1)[C].

Attempt maximal therapy for single most likely cause for several weeks and then search for coexistent etiologies.

MEDICATION

- Treatments (nasal steroids, classic antihistamines, antacids, bronchodilators, inhaled corticosteroids, PPIs, antibiotics) should be directed at the specific cause of cough.
- If history and physical exam suggest GERD, may want to trial empiric PPI therapy prior to further diagnostic testing.
- The FDA issued a public health advisory stating that OTC cough and cold medicines, including antitussives, expectorants, nasal decongestants, antihistamines, or combinations, should not be given to children <2 years. Subsequently, manufacturers have changed labeling to state “do not use” in children <4 years. In 2017, the FDA issued a contraindication to codeine for cough treatment in children <12 years.
- Routine empiric treatment of children with chronic cough with leukotriene receptor antagonists lacks evidence and cannot be recommended.

First Line

In adults:

- Nasal steroids: fluticasone, budesonide, others, 1 spray BID for those with allergic rhinitis symptoms or postnasal drip or an empiric trial of PPI (omeprazole, others) once a day

Second Line

- A peripherally acting antitussive agent has been used:
  - In patients >10 years, benzonatate (Tessalon Perles) 100 to 200 mg PO TID as needed (maximum 600 mg/day)
- Gabapentin was evaluated in a randomized, double-blind, placebo-controlled trial of patients with refractory chronic cough. Gabapentin demonstrated improved cough-specific quality of life compared to placebo. Nausea and fatigue occurred in 31%. A therapeutic trial with a risk-benefit assessment at 6 months is suggested (1)[C].
- A comparative effectiveness review of 49 studies with common opioid and nonanesthetic antitussives stated there is some efficiency for treating cough in adults, but evidence is limited (4)[C].
- Studies evaluating inhaled corticosteroid use in chronic cough for patients without additional indication such as asthma did not show consistent benefits (1)[C].

ISSUES FOR REFERRAL

Patients with chronic cough may benefit from evaluation by pulmonary, gastroenterology, ear/nose/throat (ENT), and/or allergy specialists. Consider specialist cough clinic.

SURGERY/OTHER PROCEDURES

Fundoplication may be effective for cough secondary to refractory GERD.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Consider stepwise withdrawal of medications after resolution of cough.

Patient Monitoring
Frequent follow-up is necessary to assess the effectiveness of treatment.

DIET
Dietary modification: Patients with GERD may benefit by avoiding ethanol, caffeine, nicotine, citrus, tomatoes, chocolate, and fatty foods.

PATIENT EDUCATION
- Reassure patient that most cases of chronic cough are not life-threatening and that the condition can usually be managed effectively.
- Counsel that several weeks to a month may be needed for significant reduction or elimination of cough.
- Prepare the patient for the possibility of multiple diagnostic tests and therapeutic regimens because the treatment is very often empiric.

PROGNOSIS
- >80% of patients can be effectively diagnosed and treated using a systematic approach.
- Cough from any cause may take weeks to months until resolution, and resolution depends greatly on efficacy of treatment directed at underlying etiology.

COMPLICATIONS
- Cardiovascular: arrhythmias, syncope
- Stress urinary incontinence
- Abdominal and intercostal muscle strain
- GI: emesis, hemorrhage, herniation
- Neurologic: dizziness, headache, seizures
- Respiratory: pneumothorax, laryngeal, or tracheobronchial trauma
- Skin: petechiae, purpura, disruption of surgical wounds
- Medication side effects
- Other: negative impact on quality of life

CLINICAL PEARLS
- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In patients with chronic cough, most frequent etiologies include a history of smoking, asthma, UACS, and GERD.
- The FDA issued a public health advisory stating that OTC cough and cold medicines should not be given to children <2 years. OTC cough expectorant and suppressant product labels state “do not use” in children <4 years. Codeine is contraindicated for cough treatment in children <12 years.
CHRONIC KIDNEY DISEASE
Daniel Frasca, DO

BASICS
Chronic kidney disease (CKD) is defined as structural or functional abnormalities of the kidney for ≥3 months, as determined by either pathologic abnormalities or markers of damage—including abnormalities in blood or urine tests, histology, imaging studies, or history of kidney transplant—or a glomerular filtration rate (GFR) <60 mL/min/1.73 m² for ≥3 months.

DESCRIPTION
- In 2012, Kidney Disease: Improving Global Outcomes (KDIGO) classified CKD in six categories by GFR estimation (in mL/min/1.73 m²):
  - G1: kidney damage with normal or increased GFR ≥90
  - G2: mild ↓ GFR 60 to 89
  - G3a: mild to moderate ↓ GFR 45 to 59
  - G3b: moderate to severe ↓ GFR 30 to 44
  - G4: severe ↓ GFR 15 to 29
  - G5: kidney failure: GFR <15 or dialysis
- CKD per albumin-to-creatinine ratio (ACR) category:
  - A1: normal to mildly increased: <30 mg/g or <3 mg/mmol
  - A2: moderately increased: 30 to 300 mg/g or 3 to 30 mg/mmol
  - A3: severely increased: >300 mg/g or >30 mg/mmol
- CKD is a chronic condition and will always progress. The rate of progression depends on comorbid conditions.
- System(s) affected: renal/urinary, cardiovascular, skeletal, endocrine, metabolic, hematologic, lymphatic, immune, neurologic
- Synonym(s): chronic renal failure; chronic renal insufficiency

Geriatric Considerations
GFR normally decreases with age, despite normal creatinine (Cr). Adjust renally-cleared drugs for GFR in the elderly.

Pediatric Considerations
CKD definition is not applicable for children <2 years because of lower GFR, even when corrected for body surface area. Calculated GFR based on serum Cr is used in this age group.

Pregnancy Considerations
Renal function in CKD may deteriorate during pregnancy. Cr >1.5 and hypertension (HTN) are major risk factors for worsening renal function.
- Increased risk of premature labor, preeclampsia
- ACE inhibitors (ACE-Is) and angiotensin receptor blockers (ARBs) are contraindicated due to teratogenicity. Use diuretics with caution.

EPIDEMIOLOGY
- African Americans are 3.6 times more likely to develop CKD than Caucasians.
Predominant sex: similar in both sexes; however, incidence rate of end-stage renal disease (ESRD) is 1.6 times higher in males than females.

**Incidence**
Estimated annual incidence of 1,700/1 million population

**Prevalence**
Overall prevalence of CKD is 14.2%. Unadjusted prevalence/incidence rates of ESRD (stage 5) are 1,752 and 362.4/1 million, respectively. Numbers do not reflect the burden of earlier stages of CKD (stages 1 to 4), which are estimated to affect 13.1% of the population nationwide or 26.3 million in the United States.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Progressive destruction of kidney nephrons; GFR will drop gradually, and plasma Cr values will approximately double, with 50% reduction in GFR and 75% loss of functioning nephrons mass. Hyperkalemia usually develops when GFR falls to <20 to 25 mL/min. Anemia develops from decreased renal synthesis of erythropoietin.

- Renal parenchymal/glomerular
  - Nephritic: hematuria, red blood cell (RBC) casts, HTN, variable proteinuria
    - Focal proliferative: IgA nephropathy, systemic lupus erythematosus (SLE), Henoch-Schönlein purpura, Alport syndrome, proliferative glomerulonephritis, crescentic glomerulonephritis
    - Diffuse proliferative: membranoproliferative glomerulonephritis, SLE, cryoglobulinemia, rapidly progressive glomerulonephritis (RPGN), Goodpasture syndrome
  - Nephrotic: proteinuria (>3.5 g/day), hypoalbuminemia, hyperlipidemia, and edema
    - Minimal change disease, membranous nephropathy, focal segmental glomerulosclerosis
    - Amyloidosis, diabetic nephropathy
- Vascular: HTN, thrombotic microangiopathies, vasculitis (Wegener), scleroderma
- Interstitial tubular: infections, obstruction, toxins, allergic interstitial nephritis, multiple myeloma, connective tissue disease, cystic disease, nephrolithiasis
- Postrenal: obstruction (benign prostatic hyperplasia [BPH]), neoplasm, neurogenic bladder

**Genetics**
- Alport syndrome, Fabry disease, sickle cell anemia, SLE, and autosomal dominant polycystic kidney disease can lead to CKD.
- Polymorphisms in gene that encodes for podocyte nonmuscle myosin IIA are more common in African Americans than Caucasians and appear to increase risk for nondiabetic ESRD.

**RISK FACTORS**
- Type 1 or 2 diabetes mellitus (DM) (most common)
- Age >60 years
- Cardiovascular disease (CVD) (e.g., HTN [common], renal artery stenosis, atheroemboli)
- Previous kidney transplant
- Urinary tract obstruction (e.g., BPH)
- Autoimmune disease, vasculitis/connective tissue disorder
- Family history of CKD
- Nephrotoxic drugs (high-dose or chronic nonsteroidal anti-inflammatory drugs (NSAIDs), lithium, salicylate, sulfonamide)
- Congenital anomalies, obstructive uropathy, renal aplasia/hypoplasia/dysplasia, reflux nephropathy
- Hyperlipidemia
- Low income/education/ethnic minority status
- Obesity/smoking/drug use (especially heroine)
- Chronic infection (hepatitis B, hepatitis C, HIV)

**GENERAL PREVENTION**
- Treat reversible causes: hypovolemia, infections, diuretics, drug exposure (NSAIDs, aminoglycosides, IV contrast).
- Treat risk factors: DM, HTN, hyperlipidemia, diet, smoking, and obesity; adjust medication doses to prevent renal toxicity.
- The United States Preventive Services Task Force has concluded the evidence is insufficient to assess the balance of benefits and harms in screening asymptomatic adults for CKD (1)[C]. The American College of Physicians and the American Academy of Family Physicians recommend against screening asymptomatic adults for CKD without risk factors (2)[C].

**COMMONLY ASSOCIATED CONDITIONS**
Hypertensive disease, diabetes, primary or secondary glomerulonephritis

**DIAGNOSIS**

**HISTORY**
Patients with CKD stages 1 to 3 are usually asymptomatic; can present with
- Oliguria, nocturia, polyuria, hematuria, change in urinary frequency
- Bone disease
- Edema, HTN, dyspnea
- Fatigue, depression, weakness
- Pruritus, ecchymosis
- Metallic taste in mouth, anorexia, nausea, vomiting
- Hyperlipidemia, claudication, restless legs
- Erectile dysfunction, decrease libido, amenorrhea

**PHYSICAL EXAM**
- Volume status (pallor, BP/orthostatic; edema; jugular venous distention; weight)
- Skin: sallow complexion, uremic frost
- Ammonia-like odor (uremic fetor)
- Cardiovascular: Assess for murmurs, bruits, and pericarditis.
- Chest: pleural effusion
- Rectal: enlarged prostate
- Central nervous system: asterixis, confusion, seizures, coma, peripheral neuropathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- GFR can be estimated using the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equations. A recent meta-analysis found that MDRD has greater accuracy at GFR 60, whereas the CKD-EPI is more accurate at
GFR >60 (3)[A].

- Cr clearance (CrCl) can be calculated using Cockcroft-Gault formula to determine medication adjustments.
- Urine analysis to assess for evidence of damage
  - Urine microscopy: WBC casts in pyelonephritis, RBC casts in glomerulonephritis/vasculitis
  - Urine electrolytes: sodium, Cr, urea (if on loop diuretics)
  - Albuminuria is more sensitive than proteinuria at detecting disease. Meta-analyses link CVD mortality with albuminuria.
    - Report as a ratio of albumin concentration to Cr concentration (mg/mmol or mg/g) (2)
- Ultrasound (initial imaging test of choice): small, echogenic kidneys; may see obstruction (e.g., hydronephrosis); cysts; kidneys may be enlarged with HIV and diabetic nephropathy (2).
- Doppler ultrasound to assess for renovascular disease, thrombosis
- Noncontrast computed tomography scan: obstruction, calculi, cysts, neoplasm, renal artery stenosis
- Magnetic resonance imaging/magnetic resonance angiography: Avoid gadolinium because of the risk of nephrogenic systemic fibrosis.
- Renal arteriogram for renal artery stenosis can be therapeutic (angioplasty or stenting).
- Renal scan to screen for differential function between kidneys
- Retrograde pyelogram: if strong suspicion for obstruction despite negative finding on ultrasound

**Follow-Up Tests & Special Considerations**

- Additional evaluation may be indicated to assess for complications or cause, as clinically indicated:
  - Hematology: normochromic, normocytic anemia; increased bleeding time
  - Chemistry: elevated BUN, Cr, hyperkalemia, metabolic acidosis, increased parathyroid hormone (PTH), HLD, hyperphosphatemia, decreased 25-(OH) vitamin D, hypocalcemia, decreased albumin
  - Serology: antinuclear antibody (ANA); double-stranded DNA, antineutrophil cytoplasmic antibody; complements (C3, C4, CH50); antiglomerular basement membrane (GBM) antibodies; hepatitis B, C; and HIV screening
  - Serum and urine immunoelectrophoresis
- Follow-up tests and monitoring:
  - Monitoring the parameters with frequency based on GFR and risk of progression:
    - Hb: clinically indicated for GFR ≥60, annually for 30 to 59, twice per year for <30
    - Calcium, phosphate, PTH, alkaline phosphate actively beginning at CKD stage G3a
    - 25(OH)D (calcidiol) levels with repeated testing determined by baseline values and therapeutic interventions
  - Therapeutic decisions should be based on trends rather than on a single laboratory value, taking into account all available CKD-MBD assessments.

**ALERT**

Drugs that may alter lab result:

- Cimetidine: inhibits Cr tubular secretion
- Trimethoprim: inhibits Cr and K+ secretion and may cause/worsen hyperkalemia
- Cefoxitin and flucytosine: increases serum Cr
- Diltiazem and verapamil (like ACE/ARBs) have significant antiproteinuric effects in patients with CKD.

**Diagnostic Procedures/Other**
Biopsy: hematuria, proteinuria, acute/progressive renal failure, nephritic or nephrotic syndrome

---

**TREATMENT**

**GENERAL MEASURES**
- Lowering salt intake to <2 g/day of sodium in adults, unless contraindicated
- Minimize radiocontrast exposure; prehydrate; N-acetylcysteine use is controversial. Avoid nephrotoxins (NSAIDs, aminoglycosides, etc.).
- Encourage smoking cessation, encourage weight loss (if applicable), and limit alcohol consumption.
- Protein restriction to 0.8 g/kg/day is recommended in CKD G4 to G5. CKD at risk of progression should avoid dietary protein >1.3 g/kg/day to avoid accelerating progression.
- Restrict caffeine.
- Target a1c to +/- 7.0%, given risk of hypoglycemia.

**MEDICATION**
- **HTN:** Goal in adults is BP <130/80 mm Hg if urine albumin excretion is ≥30 mg/24 hr and <140/90 mm Hg if urine albumin excretion is <30 mg/24 hr. Goal in children is <90th percentile for age, sex, and weight.
  - ACE-I or ARB recommended for diabetic and nondiabetic adults with albumin excretion >30 mg/24 hr based on evidence of reductions in proteinuria, improved CVD outcomes, and decreased progression of CKD. Monitor potassium and serum Cr (tolerate up to 30% rise unless hyperkalemia develops).
  - Additional antihypertensive agents should be selected based on the type of CKD and comorbid factors.
- **Secondary hyperparathyroidism**
  - For GFR <45, monitor for hyperphosphatemia, hypocalcemia, and vitamin D deficiency if intact PTH is elevated beyond lab normals.
  - Cinacalcet, paricalcitol (decrease PTH levels)
- **Hyperphosphatemia:** Maintain phosphate according to reference lab normals. Recommended serum phosphate maintenance levels for CKD patients:
  - Stages 3 to 5 CKD (not on dialysis): Restrict dietary phosphate to 800 to 1,000 mg/day.
    - Calcium-containing phosphate binders (with meals): calcium carbonate, calcium acetate (risk of hypercalcemia)
    - Noncalcium phosphate binders (with meals): sevelamer, lanthanum
    - Vitamin D: inactive vitamin D 25 (ergocalciferol or cholecalciferol), calcitriol (active vitamin D 1,25 [OH]): Vitamin D may increase absorption of phosphate by intestines and should not be started until serum phosphate concentration is controlled.
- **Anemia:** Hb <13 g/dL in adult males or <12 g/dL in adult females. Treat with iron replacement therapy with or without erythropoietin-stimulating agents (ESAs). Consider ESA if Hb >9 g/dL and <10 g/dL. ESA initiation not recommended for Hb >10 g/dL. If using ESA, goal Hb
range 10 to 11 g/dL, not to exceed 11.5 g/dL.

- Hyperlipidemia: Statins with low-density lipoprotein (LDL) goal is similar to coronary heart disease patients (LDL <70 to 100).
- Glycemic control: Target for HbA1c should be adjusted based on risk of hypoglycemia, comorbid conditions, and life expectancy. HbA1c may be falsely low in patients with decreased RBC; glucose logs may be more accurate reflection of glycemic control. Metformin use should be reviewed for GFR between 30 and 44 and discontinued if GFR <30 mL/min/1.73 m².
- Metabolic acidosis: Start treatment when bicarbonate <22 mEq/L with goal to maintain in normal range.

**ISSUES FOR REFERRAL**

- Nephrology consult: GFR <15: immediate
- GFR 15 to 29: urgent
- GFR 30 to 59: nonurgent referral
- GFR 60 to 89: not required unless with comorbidities
- Renal replacement: Prepare for dialysis or transplant when GFR <30 mL/min/1.73 m².

**SURGERY/OTHER PROCEDURES**

Placement of dialysis access or transplantation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Uremia: nausea/vomiting, fluid overload, pericarditis, uremic encephalopathy, resistant HTN, hyperkalemia, metabolic acidosis, hyperphosphatemia

**ONGOING CARE**

**DIET**

- Avoid or limit processed foods.
- Reduce dietary salt intake.
- Nutritional consult for CKD diet

**PATIENT EDUCATION**

- Annual influenza vaccine unless contraindicated
- Polyvalent pneumococcal vaccine if GFR <30 mL/min/1.73 m² and those at high risk of pneumococcal infection
- Hepatitis B vaccine with serologic confirmation if high risk of CKD progression and GFR <30 mL/min/1.73 m²

**PROGNOSIS**

Chronic kidney disease will always progress. The rate of progression and complications is based on its cause, GFR category, albuminuria category, and comorbid conditions. Progression is defined as decline in GFR category with 25% decrease in GFR from baseline. Rapid progression is decrease in GFR by >5 mL/min/1.73 m²/year. Patients with CKD gradually progress to ESRD. 5-year survival rate for U.S. patients on dialysis is ~35%.
COMPLICATIONS
HTN, anemia, secondary hyperparathyroidism, renal osteodystrophy, sleep disturbances, infections, malnutrition, electrolyte imbalances, platelet dysfunction/bleeding, pseudogout, gout, metabolic calcification, sexual dysfunction

ADDITIONAL READING

SEE ALSO
- Hydronephrosis; Nephrotic Syndrome; Polycystic Kidney Disease; Proteinuria
- Algorithm: Anuria or Oliguria

CODES
ICD10
- N18.9 Chronic kidney disease, unspecified
- Q63.9 Congenital malformation of kidney, unspecified
- N18.3 Chronic kidney disease, stage 3 (moderate)

CLINICAL PEARLS
- CKD is defined based on >3 months of kidney functional or structural abnormalities and classified based on GFR and albuminuria.
- ACE-I and ARB are first line for HTN treatment in CKD with albuminuria.
- Care should be taken in prescribing medication in CKD due to reduced renal clearance of certain medications.
- Consider nonurgent nephrologist referral for GFR ≤59 and urgent nephrologist referral for GFR ≤29.
CHRONIC OBSTRUCTIVE PULMONARY DISEASE AND EMPHYSEMA
Dennis Martinez, DO ● Aelja Fatima, MD ● Amit B. Patel, DO

BASICS

DESCRIPTION
- The Global Initiative for Chronic Obstructive Lung Disease (GOLD) describes COPD in the following words: COPD is a common, preventable, and treatable disease that is characterized by persistent respiratory symptoms and airflow limitation that is due to airway and/or alveolar abnormalities usually caused by significant exposure to noxious particles or gases. The chronic airflow limitation that characterizes COPD is caused by a mixture of small airways disease (e.g., obstructive bronchiolitis) and parenchymal destruction (emphysema), the relative contributions of which vary from person to person. Chronic inflammation causes structural changes, small airways narrowing, and destruction of lung parenchyma. A loss of small airways may contribute to airflow limitation and mucociliary dysfunction, a characteristic feature of the disease (1).
- This new definition no longer includes the terms “emphysema” and “chronic bronchitis.”
- Third leading cause of death in the United States (2)
- Projected to be the third leading cause of death globally by 2020 (3); 3.2 million deaths worldwide (3)

EPIDEMIOLOGY

Incidence
The incidence of COPD is 8.9/1,000 person-years (4).

Prevalence
The prevalence of COPD is 4.7% (4).

ETIOLOGY AND PATHOPHYSIOLOGY

Exposure to noxious gasses or particles (see “Risk Factors”) leading to the following pathologic processes in the lung:
- Impaired gas (carbon dioxide and oxygen) exchange
- Persistent airway obstruction
- Destruction of lung parenchyma

Genetics
- Genetics may contribute to host response to noxious gasses or particles.
- Antiprotease deficiency (due to α₁-antitrypsin deficiency) is an inherited, rare disorder due to two autosomal codominant alleles.

RISK FACTORS
- Smoking: including passive smoking and water pipe. Marijuana may also contribute (1,2,3).
- Severe pneumonia early in life including viral (5)
- Aging
- Lower level of education and poverty (5)
Asthma (1)
Indoor pollution (especially indoor biomass cooking worldwide) (5)
Occupational organic or inorganic dusts (5)

GENERAL PREVENTION
Avoidance of smoking is the most important preventive measure.
Early detection through pulmonary function tests (PFTs) in high-risk patients may be useful in preserving remaining lung function.

COMMONLY ASSOCIATED CONDITIONS
- Pulmonary: lung cancer, chronic respiratory failure, acute bronchitis, sleep apnea, pulmonary hypertension (HTN), asthma
- Cardiac: coronary artery disease, arrhythmia
- Ear/nose/throat (ENT): chronic sinusitis, laryngeal carcinoma
- Miscellaneous: malnutrition, osteoporosis, muscle dysfunction, depression

DIAGNOSIS

HISTORY
- Discuss patient’s use of tobacco and cannabis.
- Consider indoor pollution and occupational exposures (5).
- Symptoms: exertional dyspnea, chronic cough, sputum production
- Review possible causes of exacerbation (e.g., cold weather, recent exposure to URI, PNA, contact with flu, noncompliance with medications).
- Exacerbation: increased frequency of sputum production, change in sputum color, frequency and/or amount, fevers, wheezing, chest tightness/pain

PHYSICAL EXAM
- Prolonged expiration, wheezing
- Barrel chest, diminished breath sounds, distant heart sounds
- Accessory muscle use, pursed lip breathing, cyanosis
- Cachexia
- Clubbing not typical for COPD, however may indicate another process (e.g., lung cancer)

DIFFERENTIAL DIAGNOSIS
- Asthma (including occupational)
- Bronchiectasis
- Lung cancer
- Acute bronchitis
- Normal aging of lungs
- Chronic pulmonary embolism
- Sleep apnea
- Primary alveolar hypoventilation
- Chronic sinusitis
- Reactive airways dysfunction syndrome (RADS)
- Congestive heart failure (CHF)
- Bronchiolitis obliterans
Gastroesophageal reflux disease
Cystic fibrosis

**DIAGNOSTIC TESTS & INTERPRETATION**

Spirometry (the most reliable/objective measurement of airflow obstruction) (1,2,3)[A]

**Initial Tests (lab, imaging)**
- Spirometry (see “Diagnostic Procedures/Other”)
- Arterial blood gases (ABGs) may show hypercapnia and hypoxia.
- May see polycythemia, reflecting chronic hypoxia
- Imaging important to rule out other conditions
- Emphysema CXR: hyperinflation, flat diaphragms, and possibly bullous changes

**Follow-Up Tests & Special Considerations**
- Pulse oximetry to assess need for oxygen
- α₁-Antitrypsin screening for those with COPD age <45 years, have a blood relative with this disease, or spirometry out of proportion to tobacco use
- Chest CT may show parenchymal destruction and bullae.

**Diagnostic Procedures/Other**
- Pulmonary function testing without/with bronchodilator (2,3)[A]
  - Decreased postbronchodilator FEV₁:FVC ratio <0.7. This is the diagnostic criteria for airway obstruction; repeat spirometry recommended if between 0.6 and 0.8 (1)
  - Reduced FEV₁
  - Normal or decreased FVC
  - Normal or increased total lung capacity
  - Increased residual volume and functional residual capacity
  - Diffusing capacity is normal or reduced.
  - Typically not bronchodilator responsive (change in FEV₁ or FVC of 12% or greater and change in volume of 200 mL or greater)
- Staging: GOLD criteria for airflow limitation (1)
  - Stage 1: FEV₁ ≥80% predicted
  - Stage 2: FEV₁ 50–80% predicted
  - Stage 3: FEV₁ 30–50% predicted
  - Stage 4: FEV₁ <30% predicted or FEV₁ <50% predicted plus chronic respiratory failure
  - FEV₁ was previously used to grade severity; however, it was found to correlate poorly with patients’ functional capacity and risk for exacerbation (1).
- Symptom assessment:
  - COPD Assessment Tool (CAT)
  - Modified Medical Research Council (mMRC) questionnaire

**Test Interpretation**
- The ABCD assessment tool incorporates severity of patient’s symptoms and exacerbation history.
- Group A: low risk, less symptoms: 0 to 1 exacerbation per year and no prior hospitalization for exacerbation; and CAT score <10 or mMRC grade 0 to 1
- Group B: low risk, more symptoms: 0 to 1 exacerbation per year and no prior hospitalization
Group C: high risk, less symptoms: ≥2 exacerbations per year or ≥1 hospitalization for exacerbation; and CAT score <10 or mMRC grade 0 to 1

Group D: high risk, more symptoms: ≥2 exacerbations per year or ≥1 hospitalization for exacerbation; and CAT score ≥10 or mMRC grade ≥2

TREATMENT

GENERAL MEASURES

- Smoking cessation: This is the most important intervention to decrease risk (2,3)[A].
- Medications help reduce symptoms and exacerbations (2).
- Home oxygen: may improve survival; should be initiated at partial pressure of arterial oxygen (PaO₂) ≤55 mm Hg or pulse oximetry trends ≤88% (2)[A], or if PaO₂ between 55 and 60 mm Hg and evidence of erythrocytosis or cor pulmonale
- Influenza and pneumococcal immunizations (3)[B]
- Pulmonary rehabilitation
- NPPV may improve hospitalization-free survival in selected patients after recent hospitalization.

MEDICATION

Treatment is based on a combination of PFTs (GOLD criteria), symptoms (mMRC Dyspnea Scale or CAT), and risk of exacerbation (BODE index).

First Line

- Minimally symptomatic, low risk of exacerbation (Category A):
  - First line: a short-acting bronchodilator to use as a rescue drug (2)
  - Short-acting β-agonists: albuterol, levalbuterol
  - Short-acting muscarinic antagonists: ipratropium, oxitropium
- More symptomatic, low risk of exacerbation (Category B)
  - First line: regular use of long-acting bronchodilator in addition to as needed short-acting bronchodilator
  - Second line: If uncontrolled symptoms with a single long-acting agent, then use combined long-acting β-agonists (LABA)–long-acting muscarinic antagonists (LAMA) rather than steroids.
  - LABA: formoterol, arformoterol, salmeterol
  - LAMA: tiotropium, aclidinium, umeclidinium, glycopyrrolate
- Minimally symptomatic, high risk of exacerbation (Category C)
  - First line: LAMA
  - Second line:
    - LAMA-LABA combination
    - LABA and inhaled corticosteroid (ICS)
- More symptomatic, high risk of exacerbation (Category D)
  - First line: LAMA-LABA combination
  - Second line: can add triple therapy with LAMA-LABA and ICS therapy
    - PD4 inhibitor (roflumilast) if FEV₁ <50% and chronic bronchitis. Chronic macrolide therapy if active smoker or recently stopped smoking; theophylline not preferred due to
### Side Effects

**Second Line**

As above

<table>

<tr>
<td>• Theophylline: arrhythmia, CNS symptoms, nausea, vomiting</td>
<td></td>
</tr>
</tbody>
</table>

### ISSUES FOR REFERRAL

Severe exacerbation, frequent hospitalizations, age <40 years, rapid progression, weight loss, severe disease, or surgical evaluation

### ADDITIONAL THERAPIES

- Advanced therapies (surgical/bronchoscopic) for select patients
- Palliative care for select patients
- Acute COPD exacerbations: Mild to moderate exacerbations can be treated with short-acting bronchodilators and possibly short courses of steroids and/or antibiotics (5 to 7 days). Severe exacerbations require inpatient admission (see below).

### SURGERY/OTHER PROCEDURES

- Lung reduction surgery (selected cases)
- Bronchoscopic lung reduction procedures (selected cases)
- Surgical bullectomy
- Lung transplantation (selected cases)

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Severe acute exacerbation: Maintain oxygenation, short-acting inhaled β-agonists/inhaled anticholinergic agents, and oral or IV corticosteroids prednisone (up to 1 mg/kg/day commonly 40 mg/day for 5 days) (6)[A]. Antibiotics for moderate/severe exacerbations with increased sputum volume or sputum purulence; optimal antibiotic therapy has not been determined (1)[B]; noninvasive positive pressure ventilation if necessary
- May lead to acute or acute on chronic respiratory failure requiring ICU admission and intubation
- Prior to discharge: Assess proper inhaler use, prescribe proper maintenance inhalers, and ensure understanding; assess need for home oxygen.

<tr>
<td>If not already in place, have patient delineate an advance directive. Progressive nature of disease and severity of treatment methods (ventilation, etc.) make revisiting patient preferences beneficial.</td>
<td></td>
</tr>
</tbody>
</table>
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- May taper or stop oral steroids as outpatient
- Pulmonary rehabilitation for exertional dyspnea (2)[A]

Patient Monitoring
Follow-up should be initially within 4-week period and a 12-week period after an exacerbation; paying attention to symptoms, medication compliance, and the need for O₂ in 4 weeks and in addition to the above repeating spirometry in 12 weeks

DIET
Referral for nutritional support indicated in malnourished patients

PATIENT EDUCATION
American Lung Association: www.lung.org/lung-disease/copd/

PROGNOSIS
- Symptoms, exacerbation history, comorbidities, and postbronchodilator FEV₁ are the most important predictors of prognosis (1).
- Supplemental O₂, when indicated, is shown to increase survival (may only need at night) (2)[A].
- Smoking cessation improves prognosis (3).
- For severe upper lobe disease and poor control or poor postrehabilitation exercise capacity, lung volume reduction surgery may be considered.
- For very severe disease unresponsive to all interventions, patient may be candidate for lung transplant.

COMPLICATIONS
- Malnutrition, poor sleep quality, infections, secondary polycythemia
- Acute or chronic respiratory failure, bullous lung disease, pneumothorax
- Arrhythmias, cor pulmonale, pulmonary HTN

Bronchitis, Acute

**CODES**

**ICD10**

- J44.9 Chronic obstructive pulmonary disease, unspecified
- J43.9 Emphysema, unspecified
- J42 Unspecified chronic bronchitis

**CLINICAL PEARLS**

- Consider screening PFTs on any high-risk patient.
- Overnight oximetry if daytime SaO$_2$ is borderline
- Influenza/pneumococcal vaccines should be current.
- Advance directive before patient is seriously ill.
CHRONIC PAIN MANAGEMENT: AN EVIDENCE-BASED APPROACH
Jennifer Reidy, MD, MS, FAAHPM ● Vandana Nagpal, MD, FACP

BASICS
- Chronic pain is a common presenting complaint in primary care. It is typically defined as pain persisting beyond the time anticipated for normal tissue healing, usually >3 months.
- Over time, neuroplastic changes in the central nervous system transform pain into a chronic disease. Pain levels typically exceed the pathology observed on exam or imaging.
- Pain experience is inherently related to emotional, psychological, and cognitive factors.
- Use an evidence and systems based practice to safely and effectively prescribe opioid medications only when indicated for chronic, nonmalignant pain.

EPIDEMIOLOGY
Incidence
- Incidence is rising, but exact rate is unclear. Chronic pain has been reported by as many as 20–40% of patients seen in primary care settings.
- The annual economic cost of chronic pain in the United States is estimated at $560 to $635 billion (1).

Prevalence
In the United States, an estimated 50 million adults live with chronic pain. Individuals reporting severe pain are more likely to have impaired health status, use more health care, and suffer more disability (1).

ALERT
Caution: Opioid-related overdoses are at an all-time high. From 1999 to 2017, 702,000 people died from drug overdoses (http://www.cdc.gov/drugoverdose/index.html). Drug overdoses are now a leading cause of injury-related death in the United States. Two-thirds of drug-related deaths involve opioids (prescription or illicit).

ETIOLOGY AND PATHOPHYSIOLOGY
- With intense, repeated, or prolonged stimulation of damaged or inflamed tissues, the threshold for activating primary afferent pain fibers is lowered, the frequency of firing is higher, and there is increased response to noxious and/or normal stimuli (peripheral and central sensitization). The amygdala, prefrontal cortex, and cortex relay emotions related to the pain experience, and these areas undergo structural and functional changes over time.
- Patients often have an identifiable etiology (most commonly musculoskeletal problems or headache), but pain levels are often worse than observable tissue injury. Many patients have no obvious source of chronic pain.

Genetics
Current research suggests a genetic polymorphism in opioid receptors may affect patient’s
response and/or side effects to individual opioids.

**RISK FACTORS**
- Traumatic: motor vehicle accidents, repetitive motion injuries, sports injuries, work-related injuries, and falls
- Postsurgical: especially back surgeries, amputations, and thoracotomies
- Psychiatric comorbidities: substance abuse, depression, posttraumatic stress disorder (PTSD), personality disorders
- Aging: increased incidence with age but should not be considered a “normal” part of aging

**GENERAL PREVENTION**
- Prevent work-related injuries through the use of ergonomic workplace design.
- Exercise and physical therapy help prevent work-related low back pain.
- Varicella vaccine and rapid treatment of shingles to lower risk of postherpetic neuralgia
- Tight glycemic control for diabetic patients, prevention of alcohol abuse, smoking cessation

**COMMONLY ASSOCIATED CONDITIONS**
Any chronic disease and/or its treatment can cause chronic pain, including diabetes, cardiovascular disease, HIV, progressive neurologic conditions, lung disease, cirrhosis, autoimmune disease, cancer, renal failure, depression, and mental illness.

**DIAGNOSIS**
Two general categories of pain:
- Nociceptive pain (response to tissue damage): two types
  - Somatic: skin, bone, soft tissue disease; described as well localized, sharp, stabbing, aching.
  - Visceral: visceral inflammation/injury; described as poorly localized, dull, aching; may refer to sites remote from lesion; can wax and wane.
- Neuropathic pain (pathology within the nervous system): damaged peripheral or central nerves; described as burning, tingling, and/or numbness.
  - Sympathetically mediated pain: Peripheral nerve injury can cause severe burning pain, swelling of the affected limb, and focal changes in sweat production and skin appearance (e.g., complex regional pain syndrome).

**HISTORY**
- Pain history: location, onset, intensity, duration, quality, temporal pattern, exacerbating agents, alleviators, prior treatments
- Screen for personal or family history of substance abuse (including tobacco addiction), mental health conditions, domestic violence, or sexual abuse.
- Standardized tools: pain severity—Brief Pain Inventory (short form); mood—Patient Health Questionnaire-9 (PHQ-9); substance abuse—Screener and Opioid Assessment for Patients with Pain (SOAPP)
- Stratify patients according to risk of chronic opioid therapy and need for increased monitoring; a positive screen does not automatically exclude patients from opioid therapy.

**PHYSICAL EXAM**
Exam is guided by history and includes functional and behavioral assessments.

**DIFFERENTIAL DIAGNOSIS**
- Multiple medical and surgical conditions can lead to chronic pain.
- Aberrant drug-taking behaviors could be related to:
  - Inadequate analgesia ("pseudoaddiction"), disease progression, opioid-resistant pain, opioid-induced hyperalgesia, opioid tolerance, substance use disorder, self-medication of nonpain symptoms, criminal intent (diversion), and poor health literacy

**DIAGNOSTIC TESTS & INTERPRETATION**
Base testing on history, exam, and differential diagnosis.

**Initial Tests (lab, imaging)**
- Urine drug screen: qualitative analysis for drugs of abuse and quantitative analysis for individual drugs (e.g., as part of prescription opioid contract)
- Most tests are immunoassays, which detect morphine and heroin but often not other opioids. Laboratory-based chromatography/spectrometry can identify specific drugs.

**Follow-Up Tests & Special Considerations**
For chronic opioid therapy, order random urine drug screens.

**Diagnostic Procedures/Other**
- Consider interventional pain clinic for complex injections and nerve blocks, which can be diagnostic.
- If complex regional pain syndrome is suspected, a sympathetic block can be diagnostic and possibly prevent chronic pain.

**Test Interpretation**
There is a possibility of false positive urine drug screen due to commonly prescribed medications like antihistamines, antipsychotics, etc. As stated above, laboratory-based chromatography/spectrometry can identify specific drugs.

**TREATMENT**
- Goals of treatment are to restore function and decrease pain while balancing risks and benefits of therapies.
- Interdisciplinary teams offer the most effective approach to treating the physical, emotional, and behavioral aspects of chronic pain. These multidisciplinary teams include the patient, family, primary care doctor, nurse, pain management specialist, pharmacist, psychologist, psychiatrist, physical and occupational therapists, physiatrist, complementary medicine practitioners, social worker, and an addiction medicine specialist.
- Treatment should always include nonpharmacologic therapies such as exercise, cognitive-behavioral therapy (CBT), patient and family education, yoga, massage, relaxation techniques, support groups, mindfulness, meditation, and acupuncture.
- For complex regional pain syndrome, refer to pain management specialist (if available), and start treatment for neuropathic pain (if not contraindicated) in order to minimize risk of chronic pain.
GENERAL MEASURES
Keep a pain and function diary to record pain and activity level and medication use. Always begin with exercise, physical therapy, CBT, and self-management skills.

MEDICATION
- Use sequential time-limited trials of medications; start at low doses, and gradually increase until effect or dose-limiting side effects are reached. Use rational polypharmacy (e.g., an opioid + neuropathic agent) if indicated and consult with pain specialists as available and as necessary.
- Management varies depending on type of pain (neuropathic vs. nociceptive)
- For mild to moderate chronic noncancer pain
  - Acetaminophen: daily dose not to exceed total 4 g in healthy adults and 2 g in the elderly or those with hepatic disease or active or past history of alcohol use.
  - NSAIDs: Use COX-2 selective inhibitors with caution because of cardiac risks (may have less gastric risk). If high cardiac risk, consider nonselective COX inhibitor (such as naproxen) with or without gastric prophylaxis (depending on ulcer risk). Caution: Combinations can lead to serious acetaminophen or NSAID toxicities if patients exceed recommended doses.
  - Tramadol: an opioid analgesic with weak serotonin-norepinephrine reuptake inhibitor (SNRI), may be helpful in neuropathic pain but has ceiling dose, risk of seizures and has to be dose adjusted for renal and hepatic failure (initial dose 50 mg q6h PRN, ceiling dose 400 mg/day or 300 mg/day for older adults).
  - Topical agents: NSAIDs (diclofenac gel 1–3% BID), lidocaine (4% gel OTC is less effective but more affordable than 5% patch), ketamine 0.5–10% BID–QID, capsaicin 0.035–0.1% QD–QID.
- For neuropathic pain, generally treat with antidepressants or calcium channel alpha-2-delta ligands with/without topical agents
  - Classes of medications include (i) tricyclic antidepressants (desipramine [25 to 100 mg QD but start with 10 mg QD in frail elderly] and nortriptyline [25 to 100 mg QD but start with 10 mg QD in frail elderly]), (ii) SNRI antidepressants (duloxetine 30–60 mg BID), (iii) anticonvulsants (α2-δ ligands, gabapentin [initial dose 300 mg/day and titrate to max of 3,600 mg/day in 3 divided doses] and pregabalin [100 to 300 mg/day in 2 to 3 divided doses]); and (iv) last line is opioids, including tramadol.
- For moderate to severe chronic pain
  - No evidence supports any of these opioids as superior or having improved side effect profile.
  - In patients with chronic back pain, aberrant medication-taking behaviors range from 5% to 24%.
    - Avoid morphine in patients with renal insufficiency.
    - Methadone should only be prescribed by experienced providers. Methadone has many drug interactions and can contribute to potentially fatal cardiac arrhythmias.
  - Once stable dose of opioids is established, change to sustained-release formulations if pain is constant or frequent; short-acting formulations for breakthrough/episodic pain only.
– Common side effects: constipation: Senna should be prescribed at time opioids are started and importance of regular bowel movements emphasized; also nausea, sedation, mental status changes, and pruritus.
– Coprescribe nasal naloxone for at-risk patients on chronic opioids (see “Ongoing Care”) (2C).

**ALERT**
Patients on chronic opioid therapy must agree to monitoring. Use universal precautions and systems-based practice, including written agreements, random urine drug screens (testing for drugs of abuse and specifically for the drug prescribed), pill/patch counts, and other measures (see “Ongoing Care”).

**SURGERY/OTHER PROCEDURES**
Consider interventional procedures, including joint injections, nerve blocks, spinal cord stimulation, and intrathecal medication among others, as needed.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Acupuncture works well for chronic neck and back pain and fibromyalgia.
- Exercise works well in low back pain and fibromyalgia.
- For adults with chronic low back pain, consider mindfulness-based stress reduction (MBSR) or CBT (3A).
- Mind–body interventions: tai chi, hypnosis, progressive muscle relaxation, meditation.
- Yoga as effective as standard physical therapy for moderate to severe chronic low back pain (2A).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- It can be difficult to differentiate appropriate pain relief–seeking behavior from inappropriate drug seeking.
- Maintain a nonjudgmental approach.
- Assess and document benefits, pain levels, functioning, and quality of life.
- Universal precautions as a systems-based approach:
  - Informed consent for opioid therapy
  - Written agreement between patient and clinician
  - One prescriber and one pharmacy
  - No after-hours prescriptions or early refills
  - Mandatory police reporting for medication thefts
  - Random urine drug tests, pill/patch counts
  - Continue with physical therapy, counseling, psychiatric medications, and necessary treatments.
  - Participate in state’s prescription drug monitoring program: http://www.cdc.gov/drugoverdose/pdmp/.
- Taper and discontinue medications (5% dose reduction per week) if patient does not benefit, if side effects outweigh benefits. If medications are abused or diverted, more rapid taper is
appropriate. If addiction is suspected, always offer treatment for substance abuse.

- Patients on long-term opioid therapy may see improvement in pain, function, and quality of life with voluntary dose reductions (4)[A].

- Nasal naloxone
  - For patients at increased risk of overdose: history of overdose, history of substance use disorder, concurrent benzodiazepine use, high opioid doses
  - Naloxone kit: two 1 mg/mL prefilled syringes with intranasal mucosal atomization device; takes effect in 2 to 5 minutes, lasts 30 to 90 minutes

PATIENT EDUCATION
American Chronic Pain Association: https://theacpa.org

COMPLICATIONS
- Rate of addiction in chronic pain patients ~3–19%
- Definitions
  - Addiction: chronic biopsychological disease characterized by impaired control over drug use, compulsive use, and continued use despite harm
  - Physical dependence: withdrawal syndrome produced by abrupt cessation or rapid dose reduction
  - Tolerance: state of adaptation when a drug induces changes that diminish its effects over time
  - Diversion: selling drugs or giving them to persons other than for whom they are prescribed

ADDITIONAL READING
- SCOPE of Pain (Safe and Competent Opioid Prescribing Education)—Free Online Modules from Boston University School of Medicine: https://www.scopeofpain.com.
CODES

**ICD10**
- G89.29 Other chronic pain
- G89.21 Chronic pain due to trauma
- G89.28 Other chronic postprocedural pain

**CLINICAL PEARLS**
- Start with the presumption that a patient’s pain is real, even if pathophysiologic evidence is initially lacking.
- Emphasize that a pain-free life may not be possible—better function and quality of life are shared goals.
- Use a multidisciplinary approach with nonpharmacologic therapies, exercise, self-management and thoughtful medication use with clear goals, expectations, and documentation of care plan.
- Universal precautions are a systems-based approach for opioid prescription in cases of chronic pain.
CIRRHOSIS OF THE LIVER
Liam P. Burke, MD

BASICS
DESCRIPTION
A chronic disease with inflammation, necrosis, fibrosis, hepatocellular dysfunction, and vascular remodeling potentially leading to liver failure and/or cancer

EPIDEMIOLOGY
- Predominant age at diagnosis: 40 to 60 years old
- Predominant sex: male > female; more women with cirrhosis from alcohol abuse
- Liver disease and cirrhosis are the 9th leading causes of death among U.S. adult males; 12th overall

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic hepatitis C virus (HCV) (26%)
- Alcohol abuse (21%)
- Nonalcoholic steatohepatitis (NASH)/obesity (~10%)
- Hepatitis B virus (HBV) plus hepatitis D infection (15%)
- Other: hemochromatosis, autoimmune hepatitis, primary biliary cirrhosis, secondary biliary cirrhosis, biliary atresia, idiopathic biliary fibrosis, primary sclerosing cholangitis, Wilson disease, α₁-antitrypsin deficiency, granulomatous disease (e.g., sarcoidosis); drug-induced liver disease (e.g., methotrexate, α-methyldopa, amiodarone); venous outflow obstruction (e.g., Budd-Chiari syndrome, veno-occlusive disease); chronic right-sided heart failure; tricuspid regurgitation; and rare genetic, metabolic, and infectious causes
- Hepatocellular injury results in cellular hyperplasia (regenerating nodules), fibrous changes, and angiogenesis. Distortions in blood flow result in portal hypertension.

Genetics
Hemochromatosis, Wilson disease, and α₁-antitrypsin deficiency in adults are associated with cirrhosis.

RISK FACTORS
Alcohol abuse, intravenous drug abuse, obesity

GENERAL PREVENTION
- Mitigate risk factors (e.g., alcohol abuse; screen for hepatitis C); >80% of chronic liver disease is preventable.
- Limit alcohol consumption and advise weight loss in overweight or obese patients.

COMMONLY ASSOCIATED CONDITIONS
HCV, alcohol and drug abuse, diabetes, depression, obesity

DIAGNOSIS
HISTORY
- Review risk factors (alcohol abuse, viral hepatitis, family history of primary liver cancer, other liver disease, or autoimmune disease).
- Symptoms
  - Fatigue, malaise, weakness
  - Anorexia, weight loss (weight gain if ascites/edema)
  - Right upper abdominal pain
  - Bruising, bleeding, hematemesis, hematochezia, melena
  - Tea-colored urine, clay-colored stools
  - Edema, abdominal swelling/bloating, pruritus
  - Bruising, bleeding, hematemesis, hematochezia, melena
  - Absent/irregular menses, chronic anovulation
  - Diminished libido, erectile dysfunction
  - Night blindness

PHYSICAL EXAM
Physical exam may be normal until end-stage disease—many relate to manifestations of portal hypertension
- Skin changes: spider angiomas, palmar erythema, jaundice, scleral icterus, ecchymoses, caput medusa, hyperpigmentation, decreased body hair, facial telangiectasias
- Hepatomegaly (small, fibrotic liver when end-stage disease)
- Splenomegaly (if portal hypertension)
- Abdominal fluid wave, shifting dullness (ascites)
- Gynecomastia
- Dupuytren contractures
- Pretibial, presacral pitting edema, and clubbing (especially in hepatopulmonary syndrome)
- Asterixis, mental status changes (hepatic encephalopathy)
- Muscle wasting, weakness
- Fetor hepaticus (in severe portosystemic shunting)

DIFFERENTIAL DIAGNOSIS
Steatohepatitis, other causes of portal hypertension (e.g., portal vein thrombosis, lymphoma); metastatic or multifocal cancer in the liver; vascular congestion (e.g., cardiac cirrhosis); acute alcoholic hepatitis

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Aspartate aminotransferase/alanine aminotransferase (AST/ALT): mildly elevated, typically AST > ALT; enzymes may normalize as cirrhosis progresses.
- Elevated alkaline phosphatase (ALP), γ-glutamyl transpeptidase (GGT), and total/direct bilirubin
- Anemia from hemolysis, folate deficiency, and/or splenomegaly
- Thrombocytopenia (<110; 95% specific for cirrhosis)
- Impaired synthetic liver function denoted by hypoalbuminemia, low cholesterol, prolonged prothrombin time (PT), international normalized ratio (INR), and partial thromboplastin time (PTT); coagulopathy of vitamin K–dependent clotting factors (II, VII, IX, X)
- Progressive cirrhosis indicated by hyperammonemia, elevated blood urea nitrogen (BUN),
hyperkalemia, and hyponatremia

- Hepatorenal syndrome characterized by creatinine clearance < 40 mL/min (or serum Cr > 1.5) with urine volume < 500 mL/day and urine sodium < 10 mEq/L.
- Abdominal ultrasound q6–12mo to screen for hepatocellular carcinoma (HCC)
- Doppler ultrasound or elastography to assess liver parenchyma and Doppler for hepatic/portal vein

**Follow-Up Tests & Special Considerations**

Consider:
- Hepatitis serologies
- Serum ethanol and GGT if alcohol abuse suspected
- Antimitochondrial antibody to screen for primary biliary cirrhosis
- Antismooth muscle and antinuclear antibodies to screen for chronic active (autoimmune) hepatitis
- Transferrin saturation (>50%) and ferritin (markedly increased) to screen for hemochromatosis; if abnormal, check hemochromatosis (HFE) genetics/mutation analysis.
- α1-Antitrypsin phenotype screen
- Ceruloplasmin to screen for Wilson disease; if low, check copper excretion (serum copper plus 24-hour urine copper).
- α-Fetoprotein level to screen for HCC

**Diagnostic Procedures/Other**

- Liver biopsy: required for definitive diagnosis, percutaneous if INR <1.5 and no ascites; otherwise, transjugular; serologic testing gaining use as a surrogate for biopsy
- Ultrasound-based elastography: noninvasive alternative to liver biopsy, increasing availability; evaluates fibrosis
- Endoscopy if esophageal varices/portal hypertensive gastropathy are a concern
- Magnetic resonance elastography: most accurate noninvasive method in obese and/or nonalcoholic fatty liver disease (NAFLD) (1)[A]

**Test Interpretation**

Fibrous bands and regenerative nodules are classic biopsy features of cirrhosis. Other histologic patterns:

- Alcoholic liver disease: steatosis, polymorphonuclear (PMN) leukocyte infiltrate, ballooning degeneration of hepatocytes, Mallory bodies, giant mitochondria
- HBV/HCV: periportal lymphocytic inflammation
- NASH: same as alcoholic liver disease; steatosis may “burn-out” in advanced disease.
- Biliary cirrhosis: PMN infiltrate in wall of bile ducts, inflammation increased in portal spaces, progressive loss of bile ducts in portal spaces
- Hemochromatosis: intrahepatic iron stores increased via iron stain or weighted biopsy tissue
- α1-Antitrypsin deficiency: positive periodic acid–Schiff bodies in hepatocytes

**TREATMENT**

Outpatient care except for major gastrointestinal (GI) bleeding, altered mental status, sepsis/infection, rapid hepatic decompensation, or renal failure
GENERAL MEASURES

- Abstain from alcohol, drugs, hepatotoxic medications, and hepatotoxic herbs (2)[B].
- Pneumococcal, hepatitis A/B, and influenza vaccines
- Weight loss, exercise, and control of lipids/glucose (2)[B]

MEDICATION

First Line

Treatment of the underlying cause first (note prescribing precautions in decompensated cirrhosis).

- HCV: Goal is to eradicate viral RNA in serum. Latest therapies are genotype dependent.
  Typical regimens with or without cirrhosis include ledipasvir-sofosbuvir, and elbasivir-grazoprevir, and sofosbuvir-velpatasvir for up to 12 weeks’ duration. Pegylated interferon (PEG-IFN) is no longer first line.

- HBV: In compensated cirrhosis with viremia, goal of treatment is to reduce HCC risk and decompensation with 48-week therapy. If decompensated, indefinite therapy recommended. Entecavir 0.5 to 1.0 mg PO daily, tenofovir 300 mg PO daily, and telbivudine 600 mg PO daily are first line. Adefovir 10 mg PO daily second line; PEG-IFN α-2a 180 μg SC weekly for 48 weeks in compensated cirrhosis if not contraindicated; lamivudine not recommended as first-line agent due to resistance (3)[B]

- NAFLD: weight loss of 7–10% to improve histopathologic features. Improved fitness and/or >150 min/week of physical activity improves metabolic and hepatic indices (2)[B].

- Alcoholic hepatitis: Treat alcohol withdrawal; Maddrey discriminant function score for risk stratification; >32 indicates poor prognosis, patients may benefit from prednisolone 40 mg/day for 28 days with 2 to 4 week; taper to reduce short-term mortality; pentoxifylline for patients who cannot tolerate steroids

- Hereditary hemochromatosis: phlebotomy every 1 to 2 weeks as tolerated to goal serum ferritin of 50 to 100 μg/L and then 2 to 6 times per year as needed. Deferoxamine 40 mg/kg/day over 8–12 hours for 5–7 days in dyserythropoietic syndrome and chronic hemolytic anemia to reduce iron overload quickly.

- Primary biliary cirrhosis: ursodeoxycholic acid (ursodiol) 13 to 15 mg/kg PO divided BID–QID with food (3)[A]; bile acid sequestrants are first-line therapy for pruritus: cholestyramine 4 to 8 g PO BID; antihistamines; rifampicin 150 to 300 mg PO BID or naltrexone 50 mg/day can be used for pruritus if ursodiol is ineffective. Evaluate and treat for malabsorption, fat-soluble vitamin deficiencies, metabolic bone disease, hypercholesterolemia, hypothyroidism, and anemia.

- Wilson disease: initial treatment with penicillamine 1,000 to 1,500 mg/day PO BID–QID or trientine 750 to 1,500 mg/day PO BID–TID on empty stomach. Trientine 750 to 1,500 mg/day PO BID–TID is better tolerated. After 1 year, zinc acetate 150 mg/day PO BID–TID for maintenance; zinc for presymptomatic, pregnant, and pediatric populations

- Autoimmune hepatitis: Treat if AST or ALT >10 times ULN, or if either >5 times ULN and γ globulins >2 times ULN with prednisone 30 mg/day × 1 week, then 20 mg/day for 1 week, then 10 mg/day for 2 weeks with, maintenance of 5 mg/day with azathioprine 50 mg/day throughout; after induction treat to normal transaminases. Discontinue maintenance after at least 24 months of treatment if AST and ALT are normal.

- Esophageal varices: for primary prophylaxis of variceal bleed, propranolol >40 mg, carvedilol 6.25 mg or nadolol 40 mg PO daily, to lower portal pressure by 20 mm Hg, systolic pressure from 90 to 100 mm Hg, and pulse rate by 25%; PPI also indicated for portal hypertensive
gastropathy

- Ascites/edema: low-sodium (<2 g/day) diet and spironolactone 100 to 400 mg/day with or without furosemide 40 to 160 mg/day PO; torsemide may substitute for furosemide. If serum sodium <120 mmol/L, then 1.0 to 1.5 L/day water restriction. If new onset, rule out spontaneous bacterial peritonitis (SBP). If history of SBP, consider SBP prophylaxis (TMP-SMX DS daily, norfloxacin 400 mg PO daily).
- Encephalopathy: lactulose 15 to 45 mL BID; titrate to induce 2 to 3 loose bowel movements daily. Combination therapy with rifaximin (550 mg PO BID) is recommended regimen to prevent recurrent hepatic encephalopathy (4)[B].
- Pruritus: ursodiol, cholestyramine, or antihistamines (e.g., hydroxyzine)
- Renal insufficiency: Stop NSAIDs, diuretics, and nephrotoxic drugs; normalize electrolytes; and hospitalize for plasma expansion or dialysis.
- Prophylactic antibiotics for invasive procedures, GI bleeding, or history of SBP
- Proton pump inhibitor for esophageal varices requiring banding or portal hypertensive gastropathy

ISSUES FOR REFERRAL
Evaluate for liver transplant at onset of complications (ascites, variceal bleeding, encephalopathy), jaundice, or liver lesion suggestive of HCC and/or when evidence of hepatic dysfunction develops (Child-Turcotte-Pugh >7 and Model for End-Stage Liver Disease [MELD] >10).

SURGERY/OTHER PROCEDURES
- Varices: endoscopic ligation, 4 to 6 treatments (if acute bleed, use pre-endoscopic gastroscopy [EGD] octreotide as vasoconstrictor); transjugular intrahepatic shunt (TIPS) second-line or salvage therapy for acute bleed
- Ascites: if tense, therapeutic paracentesis every 2 weeks PRN; caution if pedal edema absent
- Fulminant hepatic failure: liver transplantation
- HCC: curable if small with radiofrequency ablation or resection and transplant

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Zinc sulfate 220 mg BID may improve dysgeusia and appetite; adjunct for hepatic encephalopathy
- Milk thistle may lower transaminases and improve symptoms.
- Danshen and huangqi injections may promote improvement; further studies needed

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Major GI bleeding, altered mental status, sepsis/infection, rapidly progressing hepatic decompensation, renal failure

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Regular physical conditioning may help with fatigue.

Patient Monitoring
- Once stable, monitor liver enzymes, platelets, and PT q6–12mo.
Patients >55 years with chronic HBV or HCV, elevated INR, or low platelets are at highest risk for HCC; serial α-fetoprotein and liver ultrasound screening q6–12mo in patients with cirrhosis

MRI with contrast best follow-up test for HCC if α-fetoprotein elevated and/or liver mass found on ultrasound

Endoscopy at diagnosis and every 3 years (compensated) and every 1 year (decompensated) to screen for varices

**DIET**
Protein (1.0 to 1.5 g/kg body weight), high fiber, daily multivitamin (without iron), sodium restriction (<2 g/day), combined with fluid restriction, essential if ascites/edema

**PATIENT EDUCATION**
- Educate about when to seek emergency care (e.g., hematemesis, altered mental status).
- Drug, alcohol, and smoking cessation (no cannabis)
- Update required immunizations; HCV transmission precautions

**PROGNOSIS**
- 5 to 20 years of asymptomatic disease from time of initial diagnosis
- Model for end-stage liver diseases (MELD) score and Child-Turcotte-Pugh (CTP) score historically used to provide prognostic information. These scores lack contribution of nutritional assessment. Sarcopenia (muscle wasting) suggested as an important predictor of mortality in patients with cirrhosis
- After onset of complications, death typically within 5 years without transplant
  - 5% per year develop HCC.
  - 50% of cirrhotics develop ascites over 10 years; 50% 5-year survival after ascites develop.
  - Acute variceal bleeding is the most common fatal complication; 30% mortality
  - Median survival after complications (ascites, variceal bleeding, encephalopathy) is 1.5 years.
  - With transplant, 85% survive 1 year; after transplant, ~5% annual mortality
- <25% of eligible patients receive a transplant because of donor organ shortage

**COMPLICATIONS**
Ascites, edema, infections, hepatic encephalopathy, GI bleeding, esophageal varices, gastropathy, colopathy, hepatorenal syndrome, hepatopulmonary syndrome, HCC, fulminant hepatic failure, complications after transplant (e.g., surgical, rejection, infections)

**REFERENCES**

ADDITIONAL READING

SEE ALSO

Algorithm: Cirrhosis

CODES

ICD10

- K74.60 Unspecified cirrhosis of liver
- K70.30 Alcoholic cirrhosis of liver without ascites
- K74.69 Other cirrhosis of liver

CLINICAL PEARLS

- 80% of chronic liver disease that leads to cirrhosis is preventable (primarily alcohol abuse).
- After diagnosis of cirrhosis, abdominal ultrasound every 6 months for early detection of HCC
- Update necessary immunizations and treat underlying cause (HCV, alcohol abuse, etc.).
CLOSTRIDIUM DIFFICILE INFECTION
Sally-Ann L. Pantin, MD, FAAFP ■ Thomas A. Waller, MD

BASICS
DESCRIPTION
- A gram-positive, spore-forming anaerobic bacillus that releases toxins to produce clinical disease
- Infection caused by Clostridium difficile is frequently associated with antibiotic use, hospitalization, residence at long-term care facilities, and age.
- Severity of infection can range from diarrhea to pancolitis, perforation, and death.
- System(s) affected: gastrointestinal
- Synonym(s): C. difficile–associated disease or diarrhea (CDAD); C. difficile infection; C. difficile colitis; C. diff

EPIDEMIOLOGY
Incidence
- C. difficile is a common hospital-acquired infection. The incidence is rising (1).
- There are ~15 new cases per 1,000 clinical discharges; higher with increased age (2).
- Rates of complications are also increasing (1).

Prevalence
- C. difficile causes ~25% of all cases of antibiotic-associated diarrhea.
- Prevalence of community-acquired C. difficile infection is increasing. Up to 40% of patients require hospitalization (2).
- C. difficile is a commensurate organism in 2–5% of the adult U.S. population.

ETIOLOGY AND PATHOPHYSIOLOGY
- C. difficile is an anaerobic toxin-producing, gram-positive bacillus bacteria existing in vegetative and spore forms.
- Spores can survive for months in harsh conditions and outside of the body.
- Spread by fecal–oral contact. Acid-resistant spores pass through stomach to reside mostly in the colon.
- Colonic colonization causes disruptions in barrier functions of the normal microbiome (2).
- C. difficile is noninvasive. Toxins mediate disease:
  - Toxins A (enterotoxin) and B (cytotoxin) attract neutrophils and monocytes, degrading colonic epithelial cells and causing clinical disease.
- The hypervirulent strain BI/NAP1/027 of C. difficile produces a much more virulent form of disease. It is associated with higher rates of colectomy and death.

Genetics
No known genetic factors

RISK FACTORS
- Host risk factors
  - Age >65 years
– Hospitalization or long-term health care facility
– Comorbidities, including inflammatory bowel disease, immunosuppression, chronic liver disease, and end-stage renal disease
– Enteral feeding
– Previous C. difficile infection

Factors that disrupt normal colonic microbiota:
– Exposure to antibiotics (including perioperative prophylaxis) increases risk for C. difficile infection.
– Commonly implicated antibiotics: ampicillin, amoxicillin, clindamycin (most common), cephalosporins, and fluoroquinolones
– Chronic acid suppression may allow more bacteria to reach the colon (2).

Recurrence from prior infection
– Recurrence rates are ~20%; recurrence more likely with each additional episode (2)

Can colonize ileum in patients with prior colectomy

Community-acquired C. difficile infections (no overnight admission in >12 weeks) are more frequent in patients without other risk factors (younger, no recent antibiotic exposure).

Geriatric Considerations
C. difficile is the most common cause of acute diarrheal illness in long-term care facilities. Elderly patients often have multiple risk factors (comorbid disease, antibiotic exposure, medication use).

Pediatric Considerations
- Neonates have a higher rate of C. difficile colonization (25–80%) but are generally less symptomatic than adults (possibly due to immature toxin receptors).
- Frequently serve as carrier for infection in adults

GENERAL PREVENTION
- Antibiotic stewardship program decreases the incidence of C. difficile infection.
- 2010 Society for Healthcare Epidemiology of America (SHEA)/Infectious Diseases Society of America (IDSA) guidelines for prevention (3):
  – For health care workers, patients, and visitors:
    o Contact precautions, including gloves and gowns, on entry to room
    o Alcohol-based hand sanitizers are not effective. Hand washing with soap and water before and after patient interaction is recommended.
    o Accommodate patients with C. difficile infection in private rooms, if possible.
  – Environmental cleaning and disinfection
    o Disinfect with hypochlorite or other spore-killing solution.
    o Identify and reduce environmental sources of C. difficile, including the use of nondisposable rectal thermometers.
  – Antimicrobial restrictions
    o Minimize the frequency and duration of antibiotic therapy. Use particular care when prescribing commonly implicated antibiotics.

COMMONLY ASSOCIATED CONDITIONS
Pseudomembranous colitis, toxic megacolon, sepsis, colonic perforation
DIAGNOSIS

HISTORY
- Age and underlying comorbidities
- Recent antibiotic use
- Diarrhea (defined as >3 stools in 24 hours) that is watery, foul-smelling, and sometimes bloody (1)
- Fever (<10%), anorexia, nausea
- Recent hospitalization or stay at nursing facility

PHYSICAL EXAM
- Mild or moderate: cramping and lower abdominal pain
- Severe: fever, nausea/vomiting, dehydration
- Severe, complicated: shock, peritonitis, ileus

DIFFERENTIAL DIAGNOSIS
- Acute abdomen
- Antibiotic-associated diarrhea
- Inflammatory bowel disease
- Enteric infections
- Foodborne illness

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- The optimal diagnostic test is unclear (4).
- C. difficile can be identified by polymerase chain reaction (PCR)-based testing; rapid, highly sensitive, and highly specific (2)[B]
- C. difficile can be identified by immunoassays or nucleic acid amplification test (NAAT):
  - Glutamate dehydrogenase (GDH) antigen, in both toxic and nontoxic strains of C. difficile (sensitivity, 85–95%; specificity, 89–99%)
  - Toxins (A/B or A); rapid, inexpensive, easy to use (sensitivity 63–94%)
- Stool culture is the most sensitive; non–toxin-producing strains are also detected.
- Repeat testing during the same episode of diarrhea is not recommended. Stool carriage persists for 3 to 6 weeks after successful treatment (2)[A].
- Routine radiologic examination is not recommended in the absence of signs of systemic disease or clinical suspicion for complicated/severe disease.
  - Plain films may show thumbprinting and colonic distension.
  - CT may show mucosal thickening, colonic wall thickening, pericolonic inflammation, or signs of complicated infection in severe cases (i.e., extra-luminal air).

Diagnostic Procedures/Other
Endoscopy can evaluate for presence of pseudomembranes and exclude other conditions.
- Although not all patients with C. difficile infection have pseudomembranes, their presence is pathognomonic.
- Flexible sigmoidoscopy may miss 15–20% of pseudomembranes (from the proximal colon).

Test Interpretation
SHEA/IDSA guidelines (3)
- Mild or moderate disease: leukocytosis with white blood cell (WBC) count <15,000 cells/μL and a serum creatinine level <1.5× the premorbid level
- Severe, uncomplicated disease: leukocytosis with WBC count >15,000 cells/μL or a serum creatinine level >1.5× the premorbid level
- Severe, complicated disease: hypotension, sepsis, markedly elevated WBC count, and imaging findings of complicated disease

TREATMENT

GENERAL MEASURES
- Antimotility agents are contraindicated.
- Avoid indiscriminate use of antibiotics.
- Proton pump inhibitors are associated with recurrent infection but have not been shown to be causal.
- Discontinue offending antibiotic, whenever possible.

MEDICATION

First Line
- Mild or moderate infection (4)[A]
  - Vancomycin 125 mg given QID for 10 days
  - Fidaxomicin 200 mg given BID for 10 days
  - If above agents are unavailable: metronidazole, 500 mg 3 times per day PO for 10 days
  - If patient is unable to take oral medications, then intravenous (IV) metronidazole or intraluminal (PO) vancomycin can be used.
- Severe infection (4)[A]
  - Enteral vancomycin is first-line therapy in patients with severe C. difficile infection:
    - 125 mg PO QID for 10 to 14 days
    - Fidaxomicin 200 mg given BID for 10 days
    - Vancomycin retention enema if unable to take PO or if there is evidence of poor gastrointestinal motility
- Severe, complicated infection—consider surgical and critical care consultation (4)[A].
  - VAN 500 mg PO QID or by nasogastric tube. If ileus, consider adding rectal instillation of VAN and
  - Intravenously administered metronidazole (500 mg every 8 hours)
- First recurrence
  - If a standard regimen was used for the initial episode, use vancomycin taper: 125 mg QID for 10 to 14 days, BID for a week, once per day for a week, and then every 2 or 3 days for 2 to 8 weeks or
  - Fidaxomicin 200 mg given BID for 10 days if VAN was used for the initial episode
- Second recurrence
  - Vancomycin taper and/or pulse: vancomycin 125 mg PO QID for 10 to 14 days, then 125 mg PO BID for 7 days, then 125 mg PO once daily for 7 days, and then 125 mg PO every 2 to 3 days for 2 to 8 weeks:
    - Pulse dosing every 2 to 3 days allows spores to germinate and then be killed or
– Vancomycin 125 mg PO QID for 10 days followed by rifaximin 400 mg 3 times daily for 20 days, OR
– Fidaxomicin 200 mg given BID for 10 days, or
– Fecal microbiota transplantation

**ALERT**
When using vancomycin to treat *C. difficile* infection, use oral or rectal formulations. IV formulations (not excreted into the colonic lumen) are ineffective.

**Second Line**
- Oral metronidazole
  - 500 mg PO 3 times daily for 10 to 14 days
- Vancomycin: for patients who cannot tolerate or have failed metronidazole therapy and for pregnancy
- Fecal transplant: stool from healthy, screened donor. Administered via either rectal or oral route. Highly effective for recurrent infections (80–90% cure rate) after offending antibiotic stopped; recipient gut flora transformed in as few as 3 days following fecal transplantation (5) [A].

**SURGERY/OTHER PROCEDURES**
- Severe abdominal pain or signs of hemodynamic instability in the setting of known infection should prompt surgical and critical care consultation.
- Perforation of the colon (4)[A]

**ALERT**
BI/NAP1/027 strain is commonly associated with fulminant colitis, often requiring surgical intervention in younger patients with severe disease.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Adjunctive IV immunoglobulin (IVIG) has shown promise; more data needed before routine use
- Probiotics *Lactobacillus acidophilus* and *Saccharomyces boulardii* have inhibitory effects on *C. difficile* and can help prevent *C. difficile* infection.
- Other investigational treatments:
  – Newer antibiotics (rifalazil, tolevamer, and ramoplanin)
  – Monoclonal antibodies to modulate toxin effects
  – Vaccine form of *C. difficile* antitoxin antibody

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization
  – Hypovolemia
  – Inability to keep up with enteric losses
  – Hematochezia
  – Electrolyte disturbances
- IV fluids to maintain volume status
- Discharge criteria
  – Decreased diarrhea severity and frequency
  – Tolerating oral diet and medications
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Do not repeat testing for toxins because patients may shed for weeks following an acute infection.

Patient Monitoring
- Relapses of colitis occur in 15–30%.
- Relapses typically occur 2 to 10 days after discontinuing antibiotics.

DIET
- Regular diet
- NPO if severe colitis and surgical evaluation pending

PATIENT EDUCATION
Educate patients about C. difficile transmission, the importance of hand washing and not relying on alcohol-based sanitizers, and the appropriate use of antibiotics.

PROGNOSIS
- Most patients improve with conservative management and oral antibiotics.
- 1–3% of patients develop severe/fulminant colitis requiring emergency colectomy.

REFERENCES

ADDITIONAL READING
- McCollum DL, Rodriguez JM. Detection, treatment, and prevention of Clostridium difficile

**CODES**

**ICD10**
A04.7 Enterocolitis due to Clostridium difficile

**CLINICAL PEARLS**

- C. difficile is spread by fecal–oral contact.
- Alcohol-based hand sanitizers are ineffective against C. difficile. Wash hands with soap and water.
- Testing and treatment of asymptomatic patients is not recommended.
- C. difficile and organismal by-products (e.g., toxin) are identifiable from stool samples.
- Patients may shed organism or toxin for weeks after treatment. Repeat toxin assays following treatment are not helpful.
- Vancomycin or fidaxomicin is now considered first line.
COLIC, INFANTILE
Daniel T. Lee, MD, MA  Arthur Ohannessian, MD  Phillip Charles Brown, MD

BASICS

DESCRIPTION
- Colic is defined as excessive crying in an otherwise healthy baby.
- A commonly used criteria is the Wessel criteria or the Rule of Three, when crying lasts for:
  - >3 hr/day
  - >3 days/week
  - Persists >3 weeks
- Many clinicians do not strictly adhere to the criterion of persistence for >3 weeks because few parents or clinicians will wait that long before evaluation or intervention.
- Some clinicians feel that colic represents the extreme end of the spectrum of normal crying, whereas most feel that colic is a distinct clinical entity.

EPIDEMIOLOGY

Incidence
- Predominant age group is between 2 weeks and 4 months of age.
- Equal predominance among males and females, breastfed vs. formula fed, and full term vs. preterm.

Prevalence
- Wide range between 8% and 40% of infants, however, more likely affects between 10% and 25% of infants
- Causes 10 to 20% of pediatric visits during the early weeks of an infant’s life

Pediatric Considerations
This is a problem during infancy.

ETIOLOGY AND PATHOPHYSIOLOGY
The cause is unknown. Factors that may play a role include the following:
- Infant gastroesophageal reflux disease
- Allergy to cow’s milk, soy milk, or breast milk protein
- Fruit juice intolerance
- Swallowing air during the process of crying, feeding, or sucking
- Overfeeding or feeding too quickly; underfeeding has also been proposed.
- Inadequate burping after feeding
- Family tension and/or stress
- Parental anxiety, depression, and/or fatigue
- Parent–infant interaction mismatch
- Infant’s inability to console him- or herself when dealing with stimuli
- Possible early manifestation of childhood migraine
- Increases in the gut hormone motilin, causing hyperperistalsis
- Functional lactose overload (i.e., breast milk that has a lower lipid content can have faster transit time in the intestine, leading to more lactose fermentation in the gut and hence gas and distension)
- Alterations in fecal microflora
- Tobacco smoke exposure
- Prenatal exposure to maternal smoking or nicotine replacement therapy

**RISK FACTORS**
- Physiologic predispositions in an infant may play a role, but no definitive risk factors have been established.
- Emerging data suggest maternal smoking or exposure to nicotine replacement therapy during pregnancy is associated with higher incidence of infantile colic.
- Infants with a maternal history of migraine headaches are twice as likely to have colic.

**GENERAL PREVENTION**
Colic is generally not preventable.

---

**DIAGNOSIS**

**HISTORY**
- Evaluation for Wessel criteria: Crying lasts for >3 hr/day, >3 days/week, and persists >3 weeks.
- Episodes usually have a clear beginning and end.
- The crying is generally spontaneous, without preceding events triggering the episodes.
- The crying is typically different from normal crying. Colicky crying may be louder, more turbulent, variable in pitch, and appears more like screaming.
- The infant may be difficult to soothe or console despite all of the parents’ efforts.
- The infant acts normally when not colicky.
- Assess the support system of caregivers and families, including coping skills.

**PHYSICAL EXAM**
- A comprehensive physical exam is normal.
- Because excessive crying may be a risk factor for abuse, be sure to examine the child carefully for signs of shaken baby syndrome or other types of child abuse.

**DIFFERENTIAL DIAGNOSIS**
Any organic cause for excessive or qualitatively different crying in infants such as:
- Infectious causes such as meningitis, sepsis, otitis media, or urinary tract infection (UTI)
- Gastrointestinal causes such as gastroesophageal reflux disease, intussusception, lactose intolerance, constipation, anal fissure, or strangulated hernia
- Trauma, which includes foreign bodies, corneal abrasion, occult fracture, digit or penile hair tourniquet syndrome, or child abuse

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Infantile colic is a clinical diagnosis. No testing is typically performed unless clinical symptoms imply other causes (UTI, weight loss, etc.).
Diagnostic Procedures/Other
A thorough history and physical exam should be performed to rule out other causes. Otherwise, no diagnostic procedures or imaging are indicated.

TREATMENT

GENERAL MEASURES
- Soothe by holding and rocking the baby (1)[B].
- Use a pacifier (1)[B].
- Use of gentle rhythmic motion (e.g., strollers, infant swings, car rides) (1)[B].
- Place near white noise (e.g., vacuum cleaner, clothes dryer, white noise machine) (1)[B].
- Crib vibrators or car ride simulators have not proven to be helpful (1)[B].
- Increased carrying or use of infant carrier has not been shown to improve colic (1)[B].
- Burping does not significantly lower colic events.
- Employ the 5 Ss (need to be done concurrently):
  - Swaddling: tight wrapping with blanket; may be especially beneficial in infants <8 weeks old (2)[B]
  - Side: laying baby on side
  - Shushing: loud white noise
  - Swinging: rhythmic, jiggle motion
  - Sucking: on a nipple, finger, or pacifier
  - (Bonus “S”): “Stay Calm,” the baby may not understand what is said but rather how it is said. (e.g., “Everything will be fine, I am here now”)

MEDICATION
- No medication has been found to be universally beneficial in treating infantile colic. Probiotics are safe and effective. Their use is discussed in the “Complementary & Alternative Medicine” section.
- Dicyclomine (Bentyl) has been proven beneficial, but the potential serious adverse effects, such as apnea, seizures, and syncope, have precluded its use. Furthermore, the manufacturer has made the medication contraindicated for infants <6 months (3)[B].
- Simethicone has not been shown to be beneficial (3)[B].
- Omeprazole has not been shown to be beneficial.

ISSUES FOR REFERRAL
Excessive vomiting, poor weight gain, recurrent respiratory diseases, or bloody stools should prompt referral to a specialist.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- There is no clear evidence that probiotics are more effective than placebo at preventing infantile colic; however, daily crying time may reduce with probiotic (4).
- Anecdotal evidence that car rides, both real and simulated, can be effective. You can find a 10-hour recording of a simulated car ride at the following link: https://www.youtube.com/watch?v=8KAXmJc-T_4.
- Providing “white noise,” such as running a vacuum cleaner, clothes dryer, white noise generator, or infant sound machine. Avoid excessively loud and/or prolonged noise to
minimize potential adverse effects on hearing or auditory development.
- Herbal teas and supplements may help but are not recommended because of limited, inconclusive evidence.
  - Herbal teas containing mixtures of chamomile, vervain, licorice, and balm-mint used up to TID may be beneficial. However, the study used high dosages, raising clinical concerns that this therapy may impair needed milk consumption in infants and be impractical to administer. In addition, preparations used in the study may not be commercially available in the United States.
  - There is evidence supporting the effectiveness of different preparations of fennel, such as oils, teas, and herbal compounds, in treating infantile colic (5)[A].
- A home-based intervention focusing on reducing infant stimulation and synchronizing infant sleep–wake cycles with the environment, as well as parental support, has been shown to be effective.
- Use of music may help.
- Chiropractic treatment has shown no benefit over placebo.
- Infant massage has not been shown to be helpful.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Frequent outpatient visits as needed for parental reassurance, education, and monitoring and to ensure the health of the infant and parents

**Patient Monitoring**

Follow for proper feeding, growth, and development.

**DIET**

- If breastfeeding:
  - Continue breastfeeding; switching to formula unlikely to help
  - Possible therapeutic benefit from eliminating milk products, eggs, wheat, nuts, soy, and/or fish from the maternal diet of breastfeeding mothers (1)[B]
- If formula feeding:
  - Feeding the infant in a vertical position using a curved bottle or bottle with collapsible bag may help to reduce air swallowing.
  - If no intervention or dietary change has been effective, consider a 1-week trial of hypoallergenic formulas such as whey hydrolysate (e.g., Good Start) or casein hydrolysate (e.g., Alimentum, Nutramigen, Pregestimil) (1)[B],(3)[C].
  - Adding fiber to formula also has not been shown to be helpful (1)[B].
  - Supplementing with sucrose solution may be helpful, but the effect may be short lived (<1 hour) (1,3)[B].
- Switching to soy protein formula is unlikely to be helpful.
- Despite the proposed mechanism of functional lactose overload, use of lactase enzymes in formula or breast milk or given directly to the infant has no therapeutic benefit (1)[B].

**PATIENT EDUCATION**

- Reassure parents that colic is not the result of bad parenting, and advise parents about having
proper rest breaks, adequate sleep, and help in caring for the infant.

- Explain the spectrum of crying behavior.
- Avoid over- or underfeeding.
- Instruct parents regarding beneficial feeding techniques such as improved bottles (low air, curved) and sufficient burping after feeding.
- Information for parents of colicky infants can be found at the following link from the American Academy of Family Physician: https://www.aafp.org/afp/2004/0815/p741.html

**PROGNOSIS**

- Usually subsides by 3 to 6 months of age, often on its own.
- Despite apparent abdominal pain, colicky infants eat well and gain weight normally.
- A few studies indicate temper tantrums may be more common among formerly colicky infants as studied in toddlers up to 4 years old.
- Colic has no bearing on the baby’s intelligence or future development.

**COMPLICATIONS**

- Colic is self-limiting, and there is no proven untoward lasting effects to the infant.
- Possible associations with increased risk/incidence of postpartum depression among either or both parents, child abuse, caregiver burnout, and early cessation of breastfeeding.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

ICD10
CLINICAL PEARLS

- Colic is defined as excessive crying in an otherwise healthy baby (3 hr/day, 3 day/week, persists >3 weeks).
- Excessive crying may be a risk factor for shaken baby syndrome or other forms of child abuse.
- Usually subsides spontaneously by 3 to 6 months of age
- Provide advice, support, and reassurance to parents.
- Prevent caregiver burnout by advising parents to get proper rest breaks, sleep, and help in caring for the infant.
- Employ the 5 Ss (need to be done concurrently):
  - Swaddling: tight wrapping with blanket
  - Side: laying baby on side
  - Shushing: loud white noise
  - Swinging: rhythmic, jiggle motion
  - Sucking: on a nipple, finger, or pacifier
  - (Bonus “S”): “Stay Calm,” the baby may not understand what is said but rather how it is said. (e.g., “Everything will be fine, I’m here now”)
Ischemic colitis (IC) results from decreased blood flow to the colon with resultant inflammation and tissue damage.

**DESCRIPTION**
- More common in the elderly; can affect patients of all ages
- Patients present in several ways:
  - Nonacute IC from a chronic process with irreversible ischemic injury
  - Acute IC—self-limited transient mucosal ischemia
- IC is self-limited and reversible in 80% of patients:
  - 20% of patients progress to full-thickness necrosis requiring surgical intervention.
- Most commonly, ischemia is related to a nonocclusive reduction in blood flow.
- Presentation varies, but patients with acute IC typically present with localized abdominal pain and tenderness. Frequent loose, bloody stools may be seen within 12 to 24 hours of onset.
  - 2nd most common cause (9–24%) of all patients hospitalized for acute lower gastrointestinal bleeding (1)
- Laboratory and radiographic findings are nonspecific and must be correlated with clinical presentation.
- Colonoscopy is the gold standard for diagnosis of IC.
- In the absence of complications, most patients recover with supportive care including IV fluids, bowel rest, and clinical monitoring.

**EPIDEMIOLOGY**
- Female predominance (57–76% of patients in large series have been female, especially after 69 years of age) (1)
- Evidence of IC seen in 1 of every 100 endoscopies

**Geriatric Considerations**
Rare in patients <60 years old. 70 years is the average age at diagnosis.

**Incidence**
- 4.5 to 44 cases per 100,000 in the general population
- 1 of every 2,000 hospital admissions
- True incidence may be underestimated due to nonspecific clinical manifestations.

**Prevalence**
19 cases per 100,000 in the general population

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Local hypoperfusion in the colon compromises the ability to meet metabolic demands.
  - Reperfusion injury may also play a role.
- Most commonly, an acute, self-limited process
The colon is perfused by both the superior and inferior mesenteric arteries (SMAs and IMAs) and branches of the internal iliac arteries. Occlusion of branches of the SMA or IMA rarely leads to ischemic consequences due to extensive collateral circulation.

Watershed areas of the colon (splenic flexure and rectosigmoid junction) are most susceptible to ischemic damage. Blood is carried by narrow branches of the SMA and IMA to these areas, putting them at increased risk for ischemia. The splenic flexure is supplied by the terminal branches of the SMA, and the rectosigmoid junction is supplied by the terminal branches of the IMA.

The left colon is more commonly affected than the right.

Isolated right-sided disease has the worst prognosis.

The rectum is often spared because of additional blood supply from the internal iliac arteries.

Type I: unidentified etiology
  – Likely small vessel disease; treat supportively

Type II: etiology identified
  – Most commonly follows an episode of systemic hypotension, decreased cardiac output, or aortic surgery
  – Treat the underlying cause (1)

Poor perfusion may result from systemic disease, local vascular compromise, and anatomic or functional changes in the colon itself. An occlusion of large vessels is usually not identified.
  – Hypoperfusion from shock, trauma
  – Embolic occlusion of mesenteric vessels
  – Hypercoagulable states, vasculitis
  – Sickle cell disease
  – Arterial thrombosis; venous thrombosis
  – Mechanical obstruction of the colon (e.g., tumor, adhesions, hernia, volvulus, prolapse, diverticulitis)
  – Surgical complications
  – Medications (intestinally active vasoconstrictive substances, medications that induce hypotension and thus, hypoperfusion)
  – Cocaine abuse
  – Aortic dissection
  – Strenuous physical activity (e.g., long-distance running)

Repeated episodes of ischemia and inflammation may result in chronic colonic ischemia, possible stricture formation, recurrent bacteremia, and sepsis. These patients may have unresolving areas of colitis and require segmental colonic resection.

Genetics

Various coagulopathies have been related to ischemic colitis including deficiencies of protein C, protein S, antithrombin III, and factor V Leiden mutation.

Genetic polymorphisms have been found in more young patients.

Routine coagulation testing not justified except in younger patients and patients with recurrent IC (1)

RISK FACTORS

Age >60 years (90% of patients)

Smoking (most common cause of recurrent IC) (1)

Hypertension, diabetes mellitus (1)
- Rheumatologic disorders/vasculitis
- Cerebrovascular disease, ischemic heart disease (1)
- Recent abdominal surgery
- Constipation, constipation-inducing medications (1)
- History of vascular surgery (1)
- History of ileostomy
- Chronic obstructive pulmonary disease
- Hypoalbuminemia; hemodialysis
- Hypercoagulability, oral contraceptive (1)
- Immunosuppression (via medication related affects or cytomegalovirus-induced IC) (2)
- AAA repair (IMA ligation) (1)
- IBS (1)

COMMONLY ASSOCIATED CONDITIONS
- Fibromuscular dysplasia of the superior rectal artery (1)
- Colon adenocarcinoma (1)

DIAGNOSIS
- Diagnosis is based on history, risk factors, and physical examination (3)[A].
- Laboratory values and radiographic findings are usually nonspecific (3)[A].
- Colonoscopy is diagnostic (3)[A].

HISTORY
- Abdominal pain is the most common symptom (4)[A]. Pain may be out of proportion to physical examination findings.
- Symptoms vary depending on severity (5)[A].
- Sudden-onset, mild to moderate abdominal pain with tenderness over the affected segment of bowel (5)[A]
- Sudden urge to defecate followed by passage of either bright red or maroon stool (5)[A]
- Lower GI bleeding is rarely heavy (3)[A].
- Loose, bloody bowel movements may occur, typically within 12 to 24 hours of abdominal pain onset (5)[A].

PHYSICAL EXAM
- Individual signs and symptoms are poorly predictive of IC (6)[A].
- Vital signs: hypotension; tachycardia
- Tenderness over the involved segment of bowel (5)[A]
- Abdominal distention with vomiting (due to an associated ileus) (3)[A]
- In the uncommon setting of transmural ischemia, patients may develop peritoneal signs such as rebound and guarding (7)[A].

DIFFERENTIAL DIAGNOSIS
- Infectious colitis (7)[A]
- Inflammatory bowel disease (ulcerative colitis, Crohn disease) (7)[A]
- Colon cancer (7)[A]; diverticulitis (7)[A]
- Pseudomembranous colitis (6)[A]
### DIAGNOSTIC TESTS & INTERPRETATION

- Depends on clinical presentation, extent of colonic involvement, transmural involvement, acuity (3)[A]
- CT scan is the initial diagnostic test for patients with nonspecific abdominal pain (6)[A].
- Colonoscopy most sensitive for diagnosis (3)[A]
- Radiographic tests and laboratory values are otherwise nonspecific (6)[A].

### Initial Tests (lab, imaging)

- The following lab markers of ischemia are not specific to IC but can help determine disease severity (6)[A]:
  - Complete blood count (leukocytosis) (6)[A]
  - BMP, arterial blood gas (signs of metabolic acidosis) (6)[A]
  - Lactate, lactate dehydrogenase, creatine phosphokinase, amylase (6)[A]
  - Alkaline phosphatase (6)[A]
  - Albumin (5)[B]

- Abdominal plain film to look for:
  - 20% of patients show signs of IC such as thumbprinting and mural thickening; may predict worse prognosis (7)[A]
  - Bowel perforation and pneumoperitoneum (7)[A]

- Abdominal CT scan with contrast (3)[A]:
  - The most common CT findings are thickening of the colonic wall and pericolonic fat stranding (5).
  - Other common CT findings include hyperdense mucosa, submucosal edema, and mesenteric inflammation (3)[A].
  - Pneumatosis, pneumoperitoneum, and free peritoneal fluid suggest advanced ischemia (3)[A].

### Follow-Up Tests & Special Considerations

- Stool cultures, fecal leukocytes, stool ova, and parasites to rule out infection (6)[A]
- Patients undergoing aortic surgery may benefit from postoperative colonoscopy within 2 to 3 days to look for signs of IC (5)[A].
- If indicated, cardiac workup including electrocardiogram, Holter monitoring, or transthoracic echocardiogram to exclude cardiogenic embolism (6)[A]
- Drug and toxicology screening (5)[A]
- If colon cancer screening is indicated, perform several weeks following recovery from the ischemic insult (1).

### Diagnostic Procedures/Other

- Colonoscopy is gold standard; sigmoidoscopy used to evaluate postoperative left-sided ischemia (3)[A].
- Cyanotic hemorrhagic tissue and edematous mucosa suggest ischemia (5)[A].
  - Segmental distribution (watershed), hemorrhagic nodules, and rectal sparing (5)[A]
  - “Colon single-stripe sign” is a single line of erythema, with a 75% histopathologic yield (5)[A].
  - Routine biopsy no longer advised, as results are typically nonspecific (3)[A]
- In cases of isolated right colon ischemia, noninvasive vascular imaging studies are recommended to evaluate acute SMA occlusion (5)[A].
Test Interpretation
- Fulminant gangrenous IC seen in 15% of cases requires surgical intervention (3)[A].
- Acute transient IC seen in 85% of cases requires clinical evaluation for further workup (3)[A].
- Biopsied specimens reveal mucosal infarction and ghost cells, which show normal cellular outlines but lack intracellular contents (3)[A].

TREATMENT
- Treatment depends on disease severity (3)[A].
- Continuous clinical monitoring, including vital signs and serial abdominal exams (7)[A]
- In the absence of colonic necrosis or perforation, most patients respond to supportive care (1)[A]:
  - Bowel rest (5)[A]
  - IV fluids to maintain hemodynamic stability (5)[A]
  - Avoid intestinally active vasoconstrictive medications (5)[A].
  - Avoid systemic corticosteroids—may worsen ischemia and increase risk of perforation (3)[A].
  - If ileus is present, place nasogastric tube (3)[A].
- If radiographic abnormalities present, serial abdominal x-rays help follow improvement (5)[A]
- If signs of clinical deterioration are present despite supportive care (increased abdominal pain, peritoneal signs, persistent diarrhea, bleeding, or sepsis), consider surgery (3)[A]

MEDICATION
First Line
Broad-spectrum antibiotics covering aerobic and anaerobic bacteria to avoid bacterial translocation secondary to colonic mucosal damage (5)[A]
- Ciprofloxacin 400 mg IV BID or 500 mg PO BID
- Metronidazole 500 mg PO/IV TID

ISSUES FOR REFERRAL
- If cardiac workup reveals CHF or cardiac arrhythmias, initiate appropriate medical treatment (5)[A].
- If signs of clinical deterioration are present despite supportive care (increased abdominal pain, peritoneal signs, persistent diarrhea, bleeding, or sepsis), consider surgery (3)[A].

SURGERY/OTHER PROCEDURES
- 20% of patients require surgical intervention (4)[A].
- Pneumatosis intestinalis, portal vein air, or free peritoneal air are indications for urgent surgery (3)[A].
- Surgery may be indicated for:
  - Peritoneal signs, increased abdominal tenderness, new-onset shock, lactic acidosis, or acute renal failure (3)[A]
  - Diarrhea, lower GI bleeding, or exudative colitis persisting past 14 days (3)[A]
- Most common surgical intervention is colectomy with end ileostomy (6)[A].
- Cholecystectomy may prevent resuscitation-related acute acalculous cholecystitis (3)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Ginkgo biloba extract has been studied as an adjunct to general treatment
- Weight loss supplements/herbal supplements (Ephedra, ma huang, bitter orange, white willow bark) have been implicated in cases of IC.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- ICU patients represent a difficult population to diagnose IC given the concurrent comorbidities and clinical care (sedation/ventilation) that can mask the characteristic signs and symptoms.
- Consider bedside colonoscopy in critically ill patients.

ONGOING CARE

DIET
- Bowel rest until symptoms resolve
- Parenteral nutrition for patients needing prolonged bowel rest who have contraindications to surgery

PATIENT EDUCATION
Risks of ischemic colitis with the use of weight loss medications/herbal supplements

PROGNOSIS
- In most patients, IC symptoms resolve in 24 to 48 hours.
- Radiographic or endoscopic resolution within 2 weeks
- Right-sided IC is the most significant predictor of outcome. Patients with right-sided IC have a 2-fold increase in mortality and a 4-fold increase in morbidity (5).
- Secondary cardiovascular prevention minimizes recurrence.
- Male gender, low hemoglobin, low serum albumin, high blood urea nitrogen, and presence of metabolic acidosis are poor prognostic factors (1).
- Chronic kidney disease, chronic obstructive pulmonary disease, long-term care facilities increase mortality in IC (1).

COMPLICATIONS
20–30% of patients develop chronic IC, with persistent diarrhea or stricture formation requiring surgery.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- K55.9 Vascular disorder of intestine, unspecified
- K55.0 Acute vascular disorders of intestine
- K55.1 Chronic vascular disorders of intestine

CLINICAL PEARLS

- Suspect IC in patients with multiple risk factors who present with abdominal pain and loose bloody stools.
- Colonoscopy is the diagnostic gold standard.
- Most often, IC is self-limited, responding well to conservative management with IV fluids, bowel rest, and empiric broad-spectrum antibiotics.
- Peritoneal signs or lack of clinical improvement suggests more extensive ischemia and need for surgical intervention.
- Right-sided IC is associated with higher morbidity and mortality.
BASICS

DESCRIPTION

- Colon and rectal cancers (CRC) are often grouped together but are two distinct clinical entities that differ in their prognosis, presentation, staging, and management.
- CRC is the second leading cause of cancer deaths and the third most common cancer in men and women in the United States.
- Screening for colon cancer reduces the incidence of and mortality from colon cancer.

EPIDEMIOLOGY

Incidence

- Estimated that in 2019 in the United States there are 101,420 new cases of colon cancer and 44,180 new cases of rectal cancer per the American Cancer Society.
- Colorectal cancer is expected to cause about 51,020 deaths during 2019 (1).
- Incidence is relatively equal between men and women. Some databases suggest a trend toward increased incidence in the under-50 population.

Prevalence

- The lifetime risk for developing colon cancer in the United States is about 1 in 22 (4.49% for men and 1 in 24 (4.15%) for women.
- Incidence and death rates have been declining due to improved screening, prevention, and treatment.

ETIOLOGY AND PATHOPHYSIOLOGY

- Progression from the first abnormal cells to the appearance of colon cancer usually occurs over 10 to 15 years, a disease characteristic that contributes to the effectiveness of screening and prevention.
- High-risk polyp findings include multiple polyps, villous or dysplastic polyps, and larger polyps. Hyperplastic polyps are less likely to evolve into CRC.
- Multiple genetic and environmental factors have been linked to the development of CRC.

Genetics

- <10% of CRC cases are linked to an inherited gene. Patients with early onset CRC have a higher percentage of genetic causes, suggesting that genetic counseling and perhaps a colorectal-cancer specific multigene panel could be recommended for patients with early-onset CRC.
  - Many of these are inherited in an autosomal dominant fashion:
    - APC, a tumor suppressor gene, is altered in familial adenomatous polyposis (FAP).
    - Genes encoding DNA mismatch repair (MMR) enzymes are implicated in hereditary nonpolyposis colon cancer (HNPCC), formerly Lynch Syndrome, including: hMLH1, hMSH2, hMSH6, hPMS1, hPMS2 and others.
    - STK11, a tumor suppressor gene, is altered in Peutz-Jeghers syndrome.
  - A smaller portion of patients with familial CRC may have a recessive gene.
MUTYH defects lead to issues with the base excision repair gene. This MUTYH-associated polyposis (MAP) may present as a variant form of FAP.

Sporadic cases of CRC have been linked to oncogenes: KRAS, C-MYC, C-SRC, HER-2/neu, BRCA1, BRCA2, TP53, and others.

RISK FACTORS

- Age
  - >90% of people diagnosed with sporadic colon cancer are >50 years of age.

- Personal history of colorectal polyps
  - Risk increases with multiple polyps, villous polyps, larger polyps (>1 cm), and presence of dysplasia.

- Personal history of cancer
  - 30% increase in risk of developing metachronous (new primary tumors unrelated to the patients’ previous cancers) colon cancer
  - 2–4% incidence of local recurrence with colon cancer, 3–5% incidence of synchronous colon cancer
  - History of radiation therapy to the abdomen/pelvis

- Personal history of inflammatory bowel disease (IBD)
  - Prevalence of CRC in ulcerative colitis and Crohn disease is ~3%, with a cumulative risk of CRC of 2% at 10 years, 8% at 20 years, and 18% at 30 years.
  - Determined by severity, duration, and extent of inflammation
  - Ulcerative colitis with pancolitis confers up to a 10-fold risk of CRC, occurring around 8–10 years after initial diagnosis of pancolitis.

- Family history of CRC
  - Having a single first-degree relative with a history of CRC increases risk ~1.7-fold.
  - Risk is more than double for those who have a history of CRC or polyps in:
    - Any first-degree relative <50 years of age
    - ≥2 first-degree relatives, regardless of age
    - 1 first-degree and 1 second-degree relative

- Inherited syndromes
  - HNPCC
    - Often develops at young age (average age at diagnosis of CRC is 48 years)
    - Often presents with right-sided lesions, and cancer often recurs
    - Lifetime risk of CRC is 52–69%; also associated with endometrial and other cancers
    - Accounts for ~3% of all CRCs
  - FAP
    - Affected individuals develop hundreds to thousands of polyps in colon and rectum, typically presenting during childhood.
    - CRC usually present by age 40 years in untreated patients
    - Accounts for ~1% of CRCs
    - Variants include Gardner and Turcot syndromes as well as AFAP (attenuated FAP).
  - Peutz-Jeghers syndrome
    - Individuals may have hyperpigmented mucocutaneous lesions (mouth, hands, feet) and large polyps in GI tract discovered as an adolescent.
    - 81–93% risk for CRC and increased risk for other cancers
  - BRCA1 and BRCA2 syndromes
    - Some data suggests that carriers of BRCA1 may have increased risk for early CRC;
however, more evidence is needed to recommend early screening.

- **Race and ethnicity**
  - African Americans have the highest CRC incidence and mortality rates in the United States. It is unclear whether this is inherited or due to lower rates of access to screening.
  - Colonoscopy is underutilized, particularly in minorities.
  - Several gene mutations have been identified among Ashkenazi Jews, but there is not substantial evidence to adjust screening.

- **Lifestyle factors**
  - Smoking, obesity, sedentary activity, insulin resistance, high-fat and low-fiber diet

### GENERAL PREVENTION

Several options exist for colon cancer screening. Stool-based testing such as guaiac fecal occult blood test (gFOBT) and fecal immunochemical test (FIT) or FIT-DNA tests are less invasive, but endoscopic testing (flexible sigmoidoscopy or colonoscopy) offers ability to provide intervention if polyp discovered.

- **Lifestyle factors that may reduce risk:**
  - No study has evidence strong enough to modify risk stratification/screening based on protective factors.
  - Regular physical activity, diet high in fiber and fruits/vegetables
  - There is conflicting evidence on folic acid, calcium, vitamin D, magnesium, NSAIDs, fish oil, statins

### ALERT

The U.S. Preventive Services Task Force (USPSTF) strongly recommends screening for colorectal cancer beginning at 50 years (American Cancer Society and some others recommend initiating screening at 45 years) and continuing until 75 years. USPSTF gives this an “A” grade, meaning screening’s benefits far outweigh its harms. For persons ages 76–85 years old, screening should be based on overall health status and life expectancy and should involve shared decision making between the patient and health care provider.

- **Screening methods:**
  - Visualization-based tests:
    - Colonoscopy every 10 years
    - Flexible sigmoidoscopy every 5 years
    - Flexible Sig. every 10 years + FIT yearly
  - Stool-based tests:
    - FIT annually
    - Fecal occult blood testing annually
    - FIT-DNA (sDNA) test every 1–3 years
  - For patients who have a positive FIT, gFOBT, or stool DNA test, colonoscopy is recommended.

- **Screening in high-risk groups:**
  - The American College of Gastroenterology recommends screening African American patients starting at age 45 years.
  - People with a history of polyps need frequent colonoscopy screening, with the interval depending on polyp number, size, and histology.
  - People who have a first-degree relative or two second-degree relatives with CRC or adenomatous polyps before age 60 years should begin colonoscopy at age 40 or 10 years
younger than the youngest age of relative at cancer diagnosis, whichever is earlier.

- People with IBD should have regular surveillance colonoscopy with biopsies to detect dysplasia; guidelines generally indicate starting surveillance by 8 to 10 years of onset of symptoms followed by surveillance every 1 to 2 years.

- People with prior abdominal/pelvic radiation should be screened; however, recommendations vary, typically starting between 30–40 years and occurring every 5–10 years thereafter.

- Genetic testing may be appropriate for individuals with a strong family history of CRC or polyps:
  - Family members of a person with HNPCC should start colonoscopy at 25 years.
  - Individuals with suspected FAP should have yearly flexible sigmoidoscopy beginning at age 10 to 12 years; if polyps are seen, a colonoscopy is recommended. Annual screening by visualization is recommended. Those who test positive for the gene linked to FAP may consider colectomy.

**Frequency of screening for routine follow-up:**

- **<1 year:**
  - Following piecemeal (unable to remove with single loop) removal of a large polyp >15 mm
  - Serrated polyposis syndrome meets one of the following criteria:
    - At least 5 serrated polyps proximal to sigmoid, with 2 or more 10 mm
    - Any serrated polyps proximal to sigmoid with family history of serrated polyposis syndrome
    - 20 serrated polyps of any size throughout the colon

- **1 year**
  - Known FAP or at risk based on family history

- **1–2 years:**
  - Inflammatory Bowel Disease (Crohn’s or Ulcerative Colitis)

- **<3 years:**
  - >10 adenomatous polyps

- **3 years:**
  - 3–10 tubular adenomas
  - Tubular adenoma 10 mm or larger
  - Sessile serrated polyp 10 mm or larger
  - Villous adenomatous polyp
  - High-grade dysplastic adenoma or serrated polyp on pathology
  - Sessile serrated polyp with dysplasia
  - Serrated adenoma

- **5 years:**
  - 1 sessile serrated polyp <10 mm without dysplasia
  - History of colon cancer s/p surgery if initial 1-year follow-up is normal
  - One first-degree relative with CRC or advanced adenoma diagnosed before 60 years of age
  - Two first-degree relatives diagnosed at any age

- **10 years:**
  - Normal screening colonoscopy with no polyps
  - Hyperplastic polyps in rectum or sigmoid colon, <10 mm
<3 tubular adenomatous polyps on pathology, all <10 mm in size (can repeat in 5 years with risk factors)
- One first-degree relative with CRC or advanced adenoma diagnosed at 60 years or older
- Two second-degree relatives with CRC

DIAGNOSIS

HISTORY
- Most patients with colon cancer are asymptomatic.
- Microcytic, iron-deficiency anemia in men of any age and postmenopausal women is CRC until proven otherwise; therefore, evaluation must include diagnostic colonoscopy.
- Symptoms may indicate advanced disease. Common presenting symptoms include:
  - Abdominal pain or cramping
  - Change in bowel habits or in the caliber of stool (constipation, diarrhea, narrowing of stool) particularly in right-sided involvement
  - Rectal bleeding, dark stools, or blood in stool
  - Weakness or fatigue
  - Unintentional weight loss
- Other presentations may include symptoms due to the presence of metastatic lesions (lymph nodes, liver, lung, peritoneum), fever of unknown origin, and *Streptococcus bovis* or *Clostridium septicum* sepsis/endocarditis.

PHYSICAL EXAM
- Signs of anemia
- Weight loss
- Palpable abdominal mass (late presentation)
- Must include digital rectal exam

DIFFERENTIAL DIAGNOSIS
- >95% of colon cancers are adenocarcinomas. Other colonic tumors include carcinoid tumors, lymphomas, and Kaposi sarcoma in HIV.
- Many conditions can mimic CRC, including other cancers, hemorrhoids, IBD, infection, and extrinsic masses (i.e., cysts, abscesses).

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Should any screening method identify an increased risk, colonoscopy must be performed because it can be both diagnostic and therapeutic.
- For biopsy confirmed colorectal cancer, obtain:
  - CBC, ferritin with iron panel to evaluate for iron-deficiency anemia
  - CEA, primarily used for detection of persistent or recurrent disease in the future
  - Imaging to stage cancer (as below)

Follow-Up Tests & Special Considerations
- CT chest, abdomen, and pelvis to evaluate for metastatic disease; if found, brain MRI
- Intraoperative ultrasound may be used to evaluate solid organs (e.g., the liver) after tumor resection.
In selected cases, positron emission tomography (PET) may be used to detect metastatic disease.

Staging of colon cancer
- The American Joint Committee on Cancer (AJCC) tumor-node-metastasis staging is preferred.
  - Stage 0: limited to the mucosa (carcinoma in situ or intramucosal carcinoma) (Tis, N0, M0)
  - Stage I: invades mucosa (T1) or muscularis propria (T2); no invasion of lymph nodes or distant sites (T1, N0, M0 or T2, N0, M0)
  - Stage IIA: invades pericolorectal tissues; no lymph nodes or distant sites (T3, N0, M0)
  - Stage IIB: penetrates to surface of visceral peritoneum; no lymph nodes or distant sites (T4a, N0, M0)
  - Stage IIC: directly invades or adherent to other organs or structures (T4b, N0, M0)
  - Stage IIIA: invades submucosa or muscularis propria with spread to 1 to 3 lymph nodes; no distant sites (T1, N1, M0 or T2, N1, M0)
  - Stage IIIB: invades pericolorectal tissues or surface of visceral peritoneum + spread to 1 to 3 lymph nodes; no distant sites (T3, N1, M0 or T4a, N1, M0)
  - Stage IIIC: invades pericolorectal tissues or peritoneum or other organs and to ≥4 nearby lymph nodes; no distant sites (any T3 or T4, N2, M0)
  - Stage IVA: any level of invasion with spread to one organ or site (any T, any N, M1a)
  - Stage IVB: any level of invasion with spread to more than one organ or site or peritoneum (any T, any N, M1b)

**TREATMENT**

**ADDITIONAL THERAPIES**
Adjuvant chemotherapy is most clearly beneficial for stage III (node-positive) disease, in which improvements of 30% can be achieved in both disease recurrence and overall survival, compared with untreated controls. Chemotherapeutic regimens for metastatic disease may extend overall survival from 6 months to 2 years.

**SURGERY/OTHER PROCEDURES**
- Localized cancer
  - Surgery is the primary treatment
  - Without significant complications, primary anastomosis can be possible for local cancers.
  - Minimally invasive (i.e., laparoscopic) surgery has fewer complications, less blood loss, shorter hospital stay, less time to bowel movement, and lower 30-day mortality when compared to open surgery with equivalent oncologic outcomes.
- Locally advanced cancers
  - Often require multiorgan resection
- Metastatic cancer
  - Depending on patient co-morbidities and goals of care, it can be reasonable to aggressively resect metastatic lesions isolated to the liver/lungs in addition to the primary tumors.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Risk of recurrence is greatest in first 4 years; 80% in first 2.5.
- H&P and CEA every 3 to 6 months for 5 years.
- Annual CT of chest, abdomen, pelvis for 3 years
- Surveillance colonoscopy 1 year after initial surgery, then every 5 years if normal
- CEA is used to detect recurrences after resection of primary colon cancer. CEA levels decrease and normalize within 4 to 6 weeks after surgery.

PATIENT EDUCATION

PROGNOSIS

- Prognosis is primarily dependent on stage at diagnosis.
- 5-year relative survival rate after surgical resection:
  - Stage I: 85–95%
  - Stage II: 60–80%
  - Stage III: 30–60%
  - Stage IV: 25–40% following resection of hepatic metastases with clear margins

COMPLICATIONS

- Surgery: pain, deep vein thrombosis (DVT), anatomic leaks, wound infection, incisional hernia. Incidence complications are lower with minimally invasive (i.e., laparoscopic) approach.
- Chemotherapy: hair loss, nausea, vomiting, bruising, fatigue, increased risk for infections
- Radiation therapy: skin irritation, nausea, rectal pain, incontinence, bladder irritation, fatigue, and sexual problems

REFERENCES

CODES

ICD10

- C18.9 Malignant neoplasm of colon, unspecified
- C18.2 Malignant neoplasm of ascending colon
- C18.8 Malignant neoplasm of overlapping sites of colon

CLINICAL PEARLS
- Microcytic, iron deficiency anemia in men of all ages and postmenopausal women is CRC until proven otherwise, and colonoscopy should be performed.
- Colon cancer screening decreases mortality from colon cancer, thus any approved form of screening is better than none.
BASICS

DESCRIPTION
- Intraluminal colonic tissue growth; most commonly sporadic or part of polyposis syndromes
- Generally slow growing with low malignant potential; due to high prevalence in population, however, resection is generally recommended to eliminate risk.
- Size classification:
  - Diminutive ≤5 mm, small 6 to 9 mm, large ≥10 mm
- Morphologic classification:
  - Depressed, flat, sessile, or pedunculated
- Clinical significance:
  - >95% of colonic adenocarcinomas arise from polyps.

EPIDEMIOLOGY
Colorectal polyps are more common in non-Caucasian men in Western countries.

Incidence
Incidence increases with age.

Prevalence
- 15–20% of all adults
- 30% of U.S. population >50 years
- 6% of children
- 12% of children with lower gastrointestinal bleed

ETIOLOGY AND PATHOPHYSIOLOGY
- Mucosal
  - Neoplastic
    - Adenomatous polyps (tubular >80%, villous 5–15%, tubulovillous 5–15%)
    - Serrated polyps
  - Sessile serrated polyps are common, more in proximal colon, with low malignant potential if no dysplasia and significant malignant potential if dysplastic.
  - Traditional serrated adenoma is uncommon, more often noted in distal colon, with significant malignant potential.
  - Nonneoplastic polyps (hyperplastic, juvenile polyps, hamartomas, inflammatory pseudopolyps)
    - Hyperplastic polyps are very common, more in distal colon, with very low malignant potential.
    - Juvenile polyps are common in childhood, benign hamartomas, more in rectosigmoid, and not premalignant.
- Submucosal (lipomas, lymphoid aggregates, carcinoids)

Genetics
Inactivation of tumor suppressor genes as adenomatous polyposis coli (APC) or mismatch repair genes (MLH1) causes polyps to grow into cancer.

Familial adenomatous polyposis (FAP) is autosomal dominant. By age 40 years, almost all patients develop colorectal cancer (CRC).

MUTYH-associated polyposis (MAP) is autosomal recessive caused by biallelic mutations in MUTYH gene.

Juvenile polyposis syndrome (JPS) is autosomal dominant. 50–60% of patients have a mutation in the SMAD4 or BMPR1A gene. By age 35 years, 20% of patients develop CRC.

RISK FACTORS
- Family history of intestinal polyposis, polyps, or CRC
- Advancing age; male
- High-fat, low-fiber diet; tobacco use
- Excessive alcohol intake: >8 drinks a week
- Inflammatory bowel disease is associated with a decreased prevalence of colon polyps (but with higher risk of colon cancer).

GENERAL PREVENTION
- Low-fat, high-fiber diet
- Avoid smoking.
- Decrease alcohol intake.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps.
- No lower rates of CRC with azathioprine, 6-mercaptopurine, folate, calcium, multivitamins, or statins

COMMONLY ASSOCIATED CONDITIONS
Hereditary polyposis syndromes:
- Adenomatous
  - FAP
    - Classic (CFAP)
    - Attenuated (AFAP)
  - MAP
  - FAP variants:
    - Gardner syndrome
    - Turcot syndrome
- Hamartomatous
  - Peutz-Jeghers syndrome (PJS)
  - JPS
  - Familial juvenile polyposis
  - Cowden syndrome

**ALERT**
JPS imposes a higher risk of CRC, although juvenile polyps are not premalignant.

**DIAGNOSIS**

**HISTORY**
• Generally asymptomatic
• Painless rectal bleeding, bright or dark red, mixed with stools, dripping, or on wiping
• Diarrhea or mucous stool
• Abdominal pain
• Constipation
• Chronic bleeding, resulting in iron deficiency anemia
• McKittrick-Wheelock syndrome; large hypersecretory rectosigmoid villous adenoma, resulting in persistent severe diarrhea, electrolyte disorder, dehydration, and prerenal acute renal failure
• Social and family history

**PHYSICAL EXAM**
• Usually normal
• Rectal polyps noted as prolapsed or palpated on digital rectal examination (DRE)
• Fecal occult blood test (FOBT) by DRE is less effective than FOBT by stool passed spontaneously.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
• CBC; anemia with chronic bleeding
• Basic metabolic panel; electrolyte disorder with hypersecretory adenomas
• FOBT, insensitive screening test, because small polyps don’t usually bleed:
  – Guaiac (gFOBT)—uses a chemical indicator with color change in presence of blood
  – Immunochemical (iFOBT or fecal immunochemical test [FIT])—uses antibodies against human hemoglobin
• Stool DNA test is more sensitive and less specific than FIT.

**Diagnostic Procedures/Other**
• Colonoscopy is the gold standard test for detection of polyps and allows for concurrent polypectomy; not a perfect screening test, with increased miss rate with right-sided colon polyps, smaller polyp size, low quality of colon prep, less endoscopist experience
• Computed tomographic colonography (CTC) is less sensitive with flat polyps and requires excellent bowel preparation.
• Double-contrast barium enema
• Colon capsule endoscopy
• Enhanced optical technologies can potentially differentiate between neoplastic and nonneoplastic colonic lesions (1)[A].
• Enhanced optical technologies include:
  – Narrowed spectrum endoscopy (narrow-band imaging [NBI])
  – Image-enhanced endoscopy (i-scan)
  – Fujinon intelligent chromoendoscopy (FICE)
  – Confocal laser endomicroscopy (CLE)
• Patients with >10 colorectal adenomas should undergo genetic testing for APC and MAP (2) [C].

**Test Interpretation**
• Tubular adenoma
  – Gross: tends to be polypoid
- Micro: dysplastic epithelium, tubular architecture
- Villous adenoma:
  - Gross: tends to be sessile
  - Micro: dysplastic epithelium, fingerlike projections
- Tubulovillous adenomas have a combination of tubular and villous architecture.
- Hyperplastic polyps are composed of hyperplastic colonic mucosa.
- Hamartomatous polyps include muscularis mucosa.
- Juvenile polyp
  - Gross: pedunculated, smooth red mass, 1 to 3 cm (3)

**TREATMENT**

**SURGERY/OTHER PROCEDURES**
- Colonic polypectomy; diagnostic, therapeutic:
  - Snare polypectomy with electrocautery for pedunculated polyps
  - Endoscopic mucosal resection for sessile polyps
  - Endoscopic submucosal dissection
- Colorectal surgery; prophylactic in FAP and MAP and when there are numerous polyps or persistent bleeding (2,3)[C]:
  - Total colectomy ileorectal anastomosis
  - Proctocolectomy ileal pouch anal anastomosis
- Chemoprevention: NSAIDs and calcium may reduce incidence and recurrence of polyps in patients with FAP and MAP (4)[A].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up colonoscopy in:
- 10 years if no polyps or distal small hyperplastic polyps (<10 mm) (5)[B]
- 5 to 10 years if 1 to 2 small tubular adenomas (<10 mm) (5)[B]
- 3 years if 3 to 10 adenomas if any polyp ≥ 6 mm (5)[B] or if all polyps <6 mm (5)[C]
- <3 years if >10 adenomas (5)[B]
- 3 years if one or more adenomas ≥10 mm (5)[A]
- 3 years if one or more adenomas with villous features of any size or with HGD (5)[B]
- 5 years if sessile serrated polyp(s) <10 mm with no dysplasia (5)[C]
- 3 years if sessile serrated polyp(s) ≥10 mm or with dysplasia or traditional serrated adenoma (5)[C]
- 1 year if serrated polyposis syndrome (5)[B]

**Patient Monitoring**
- Colonoscopy for CRC screening starts at age 50 years and earlier for at-risk patients.
- American Cancer Society (ACS) recommends that people at average risk of CRC start screening at age 45 years through age of 75 years, may extend to 85 years, based on life expectancy and overall health.
- Stop screening if life expectancy is <10 years.
In CFAP and AFAP, screen for extracolonic manifestations: thyroid cancer, desmoid tumors, and gastroduodenal polyposis (every 6 months to 5 years) (2)[C].

In families, lifetime screening for mutation carriers (2)[C]:
- In CFAP: with sigmoidoscopy or colonoscopy, every 1 to 2 years starting at age of 10 to 11 years
- In AFAP and MAP: with colonoscopy, every 1 to 2 years starting at age of 18 to 20 years

After colorectal surgery, surveillance of the rectum (every 6 to 12 months) or pouch (every 6 months to 5 years) is indicated (2)[C].

First-degree relatives of patients with JPS require screening by colonoscopy and upper endoscopy after age 12 years (3)[C].

**Diet**

Low-fat, high-fiber diet (insufficient evidence)

**Patient Education**

Importance of colonoscopy as a screening tool

**Prognosis**

- Regression or no change in size, more with small hyperplastic polyps and with patients on NSAIDs
- Recurrence: Juvenile polyps recur in 45% of children with multiple polyps and 17% with solitary polyps (3).

**Risk factors for colon cancer (6)[A]:**
- Polyp pathology
  - Adenomatous
  - Serrated
  - With high-grade dysplasia
  - With >25% villous histology
  - Polyp size >1 cm in diameter
  - Polyps located in proximal colon
  - More than three polyps
- Recurrence rates <10% postpolypectomy

**Complications**

- Polyps: progression to cancer
- Polypectomy: bleeding 2–11%, perforation 0–1%, higher with endoscopic submucosal dissection
- Colonoscopy: complications related to anesthesia and procedure itself

**References**

ADDITIONAL READING

SEE ALSO

Colon Cancer; Rectal Cancer

CODES

ICD10

- K63.5 Polyp of colon
- D12.6 Benign neoplasm of colon, unspecified
- K51.40 Inflammatory polyps of colon without complications

CLINICAL PEARLS

- Colonoscopy is the gold standard for diagnosing polyps.
- Biopsy small hyperplastic polyps to differentiate adenomatous and serrated polyps.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps.
- The progression from normal mucosa to polyp to carcinoma takes years to develop.
COMPLEMENTARY AND ALTERNATIVE MEDICINE
Paul Crawford, MD

BASICS

DESCRIPTION

• Complementary and alternative medicine (CAM) are medical and health care systems, practices, and products that are not currently considered as part of conventional Western medicine.

• The National Center for Health Statistics (NCHS) reports nonvitamin, nonmineral dietary supplements, chiropractic or osteopathic manipulation, yoga, and massage therapy to be the most common complementary health approaches.

• Medical professionals who incorporate CAM into their medical practice often refer to this as a model of “integrative medicine.”

• Definitions and additional terms
  – Complementary medicine is used in conjunction with conventional medicine to address a health concern, for example, massage plus physical therapy for low back pain or medication plus osteopathic manipulation for recurrent headaches.
  – Alternative medicine is used in place of conventional medicine to promote healing of conditions not fully explained by the conventional biomedical model or for which the effectiveness of therapy is not yet established by clinical research.
  – Integrative medicine is the combination of allopathic medicine with CAM and may be provided to the patient by a single licensed medical professional trained in CAM or by a group of diverse health care providers.
  – Holistic is a descriptive term for a practitioner’s approach to patient care. Holistic care assesses the emotional, spiritual, mental, and physical state of wellness of the patient and works to provide comprehensive care. A holistic practice may include practitioners of different disciplines to address multiple aspects of wellness or illness.

• Biologically based therapies: diets, herbas, vitamins, supplements, flower essences

• Manipulative and body-based methods
  – Massage therapy is manipulation of soft tissues using knowledge of anatomy and physiology to restore function, promote relaxation, and relieve pain. There are different types of massage.
  – Osteopathic manipulative medicine (OMM) includes indirect techniques (e.g., muscle energy, myofascial release, osteopathy in the cranial field, and strain–counterstrain approach) and direct action techniques (high-velocity thrusts).
  – Craniosacral therapy is a gentle release of bony and fascial restrictions in the craniosacral system (cranium, sacrum, spinal cord, meninges, cerebrospinal fluid).
  – Chiropractic therapy focuses on imbalances in the musculoskeletal and nervous system to treat back, neck, and joint pain. Doctors of chiropractic (DCs) complete 4 to 5 years of intensive training in anatomy, physiology, and manipulation.

• Mind–body medicine
  – Meditation is a practice of detachment in which a person sits quietly, generally focusing on the breath, while releasing thoughts from the mind with the intention to center the self, restore balance, and enhance well-being. Mindfulness meditation involves making oneself
aware of the most immediate of activities in order to gain control over actions and anxiety.

- Spiritual practices (e.g., prayer)
- Yoga is an exercise of mindfulness, meditation, strength, and balance, composed of asanas (postures) and pranayamas (focused breathing).
- Aromatherapy uses highly concentrated plant extracts to stimulate healing. Aromatic oils are rubbed on the skin, aerosolized, or used in compresses.
- Relaxation techniques include breathing exercises, progressive muscle relaxation, and guided imagery.
- Tai chi and qi gong are Chinese exercise systems that combine meditation, regulated breathing, and flowing dance-like movements to enhance and balance chi (qi)—life force energy.

**Alternative medical systems**

- Traditional Chinese medicine incorporates Chinese herbs and acupuncture. Acupuncture is the practice of regulating chi by inserting thin needles at specific points along meridian pathways of the body. In this model, chi energy movement is responsible for animating and protecting the body; relieving pain; and regulating cellular blood flow, oxygen delivery, and nourishment.
- Ayurvedic medicine originated in India and is one of the world’s oldest medical systems. It uses healing modalities and herbs to integrate and balance the body, mind, and spirit.
- Homeopathy proposes that dilute quantities of an offending agent can stimulate innate immunity. In general, homeopathic remedies are considered safe and unlikely to cause serious adverse reactions. Only three states license homeopathic providers.
- Naturopathy includes herbs, vitamins, supplements, dietary counseling, homeopathic remedies, manipulative therapies, acupuncture, and hydrotherapy. 4-year doctoral training programs are available. 20 states/territories have licensing laws for naturopathic practitioners.

**Energy therapies**

- Reiki, which means “source energy,” is a healing practice from Japan. Laying hands lightly on the patient or holding the hands just above the body, the reiki practitioner facilitates spiritual and physical healing by stimulating life force energy.

**Common reasons patients choose CAM**

- Additive therapy to address issues not covered by conventional medical treatment
- Conventional medicine has been unsuccessful in fully addressing ailment.
- Preventive health care
- Desire for a holistic/natural approach to well-being
- Preference for noninvasive treatment options
- Concern about medication side effects
- Desire to include spiritual support into healing
- Cultural or familial belief system more aligned with “natural” solutions not provided for or supported by the standard allopathic model of health care

**Epidemiology**

- All ages use CAM; most prevalent among adults aged 30 to 69 years
- Gender ratio: female > male
- College graduates and residents of Western states are more likely to use CAM.
- Cancer survivors are more likely than the general population to use CAM.
- Six most used CAM therapies:
– Nonvitamin, nonmineral dietary supplements (18%)
– Chiropractic and osteopathic manipulation (8.5%)
– Yoga (8%)
– Massage (7%)
– Meditation (4%)
– Special diets (3%)

**TREATMENT**

Variable evidence supports safety and efficacy of:

– Meditation for lowering blood pressure (BP)
– Acupuncture for chronic low back pain (1)[B]
– Spinal manipulative therapy for prophylactic treatment of headaches
– Ginger for nausea, including that associated with chemotherapy
– Manipulation, massage, and mobilization for acute low back and posterior neck pain
– Massage therapy to promote weight gain in preterm infants
– Saffron (*Crocus sativus L.*) reduces depressive symptoms in mothers with mild postpartum depression.
– Massage (30 minutes × 3) during labor shortens the second stage and reduces pain.
– Acupuncture for chemotherapy-induced nausea and vomiting
– Tai chi for improving balance and decreasing the risk of and fear of falling in elderly
– Mind–body techniques for migraines, chronic pain, and insomnia
– Cognitive-behavioral therapy is highly effective for the treatment of insomnia (2)[A].
– Homeopathic remedy for the treatment of chemotherapy-induced stomatitis in children
– Riboflavin for migraine prophylaxis
– Horse chestnut seed extract to improve lower leg venous tone, pain, and edema
– Glucosamine for osteoarthritis and knee pain
– Yoga and meditation appear to improve endothelial function in patients with CAD and can have potential beneficial effects on depressive disorders.
– Yoga throughout pregnancy shortens labor by 140 to 190 minutes.
– Exercise in both preconception and early pregnancy reduces chance of gestational diabetes mellitus.
– Exercise has a small to moderate effect in reducing symptoms in persons with diagnosed anxiety disorders.
– Breast stimulation in late pregnancy increases successful induction of labor (number needed to treat [NNT] 3.2) and reduces postpartum hemorrhage (NNT 19).
– Oral probiotics in preterm infants to decrease necrotizing enterocolitis and reduce mortality (3)[A]
– Oral probiotics to prevent upper respiratory infections in children and influenza in the elderly
– Oral probiotics to shorten the duration of acute and antibiotic-associated diarrhea and as prophylaxis for traveler’s diarrhea
– Vitamin D 800 IU/day may reduce falls and fractures in the elderly.
– Acupuncture for recurrent headache
– Ginkgo biloba extract EGb 761 improves cognition in patients with dementia (4)[A].
– Cupping reduces chronic low back pain.
Evidence supports safety, but evidence regarding efficacy is inconclusive:
- Homeopathy for induction and augmentation of labor
- Chondroitin sulfate is ineffective for osteoarthritis.
- Sterile water injections do not reduce labor pain.
- Fish oil might be an effective treatment for hypertriglyceridemia.
- Omega-3 fatty acids may reduce inflammation and anxiety in young healthy adults.
- Dietary fat reduction for certain types of cancer
- Mind–body techniques for metastatic cancer
- Copper and magnetic bracelets for pain
- Vitamin D levels >30 ng/mL correlate with lower risk of some cancers. Adequate vitamin D intake may decrease atopy and asthma symptoms.

Evidence supports efficacy, but evidence regarding safety is inconclusive or poor:
- St. John’s wort extract for short-term treatment of depression in adults
- Licorice for gastritis
- Goldenseal

Evidence indicates serious risk:
- Black cohosh, blue cohosh, and evening primrose oil are unsafe to induce labor.
- Delay in seeking medical care or replacement of curative conventional treatment
- Use of toxic herbs or substances
- Known herb–drug interactions

ONGOING CARE

PATIENT EDUCATION
The National Center for Complementary and Integrative Health (https://nccih.nih.gov/)

COMPLICATIONS

Ginkgo, goldenseal, and St. John’s wort account for most reported herb–drug interactions.

Herbs with possible adverse effects
- Serious adverse events from herbal remedies are uncommon.
- Some ethnic medicines, as those prescribed by practitioners of Ayurveda or traditional Chinese medicine, may intentionally contain heavy metals or other toxic substances. These are usually listed by their pharmacopeial names, for example, Qian Dan = lead oxide.
- Bitter orange (Citrus sinensis): sympathomimetic; increases heart rate (HR), BP
- Black cohosh (Actaea racemosa) reduces effectiveness of statins.
- California poppy (Eschscholzia californica): may cause respiratory depression, drowsiness; contains opioids
- Cascara sagrada (Frangula purshiana): depletes serum potassium
- Chaparral (Larrea tridentata): hepatotoxic
- Ephedra (Ephedra spp.): sympathomimetic; increases HR, BP; insomnia, gastric distress
- Ginkgo (Ginkgo biloba): extravasation, increased bleeding time
- Goldenseal (Hydrastis canadensis) interferes with nearly all prescription drugs.
- Guarana (Paullinia cupana): tachycardia, hypertension; contains caffeine
- Kava (Piper methysticum): decreases use of niacin; possibly hepatotoxic
– Licorice (Glycyrrhiza spp.): Long-term use depletes serum potassium.
– Lily of the valley (Convallaria majalis): contains cardiac glycosides
– Poke root (Phytolacca species): strong gastric irritant; may cause sedation
– Senna (Cassia senna): depletes serum potassium
– Snakeroot (Aristolochia spp.): nephrotoxic
– St. John’s wort (Hypericum perforatum): numerous drug interactions; induces CYP(3A4) pathway, speeding metabolism of cyclosporine, tacrolimus, warfarin, protease inhibitors, theophylline, venlafaxine, digoxin, and oral contraceptives
– Wormwood (Artemisia absinthium): elevates serotonin level, may raise BP
– Yohimbe (Pausinystalia yohimbe): elevates BP

**Geriatric Considerations**
Ginkgo biloba commonly interacts with warfarin (Coumadin).

**Pediatric Considerations**
Iron is a leading cause of accidental poisoning in children <6 years of age. Minerals (i.e., potassium, calcium, magnesium, zinc, copper, and selenium) may cause toxicity.
- Vitamin A is the most common cause of hypervitaminosis.
- β-Carotene has a limited potential for overdose.

**REFERENCES**

**CODES**

**ICD10**
Z76.89 Persons encountering health services in other specified circumstances

**CLINICAL PEARLS**
- Oral probiotics reduce respiratory and diarrheal infections and reduce mortality in preterm infants.
- Acupuncture is effective for back pain, headaches, and knee pain.
- Cognitive-behavioral therapy reduces insomnia.
- Yoga and breast stimulation shorten labor.
- Ginkgo, goldenseal, and St. John’s wort account for most of the herb–drug interactions reported in the medical literature.
COMPLEX REGIONAL PAIN SYNDROME
Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Complex regional pain syndrome (CRPS) is a pain syndrome that can be chronic and debilitating. It is divided into two subtypes and can have significant physical and psychosocial short- and long-term disability. Most cases are a result of a physical insult to an extremity such as trauma or surgery.
  - Type I: no nerve injury (reflex sympathetic dystrophy [RSD])
  - Type II: associated with a demonstrable nerve injury (causalgia)
- Synonym(s): traumatic erythromelalgia; Weir Mitchell causalgia; causalgia; RSD; posttraumatic neuralgia; sympathetically maintained pain

EPIDEMIOLOGY

- Incidence of 5.46 to 26.2/100,000 for type I and 0.82/100,000 for type II in United States (1,2)
- Peak age 50 to 70 years
- Predominant gender: female > male (3:1, 60–81%), favoring postmenopausal
- Recent studies found 3.8% occurrence after wrist fracture and 7% occurrence after intra-articular ankle fracture—both independent strong risk for CRPS.
- More prevalent in patients that report higher than usual expected pain in early phases of trauma. Latency depends on normal injury recovery time—prolonged pain (greater than 2 months) after injury hints at diagnosis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Poorly understood activation of abnormal sympathetic reflex that lowers pain threshold
  - Increased excitability of nociceptive neurons in the spinal cord; “central sensitization”
  - Exaggerated responses to normally nonpainful stimuli (hyperalgesia, allodynia)
- Type II is associated with physical injury to nerve.
- Emerging information reveals CNS changes (functional, anatomic, biochemical) in addition to spinal level changes. Increased levels of immunomodulators suggest autoimmune component.

Genetics

No known genetic pattern

RISK FACTORS

- Minor or severe trauma (upper extremity fracture—particularly distal radius noted in 44% of those with CPRS)
- Surgery (particularly carpal tunnel release)
- Lacerations
- Burns
- Frostbite
- Casting/im immobilization after extremity injury
- Penetrating injury
- Polymyalgia rheumatica
Myocardial infarction (MI)
Cerebral vascular accident

GENERAL PREVENTION
- Early mobilization after fracture, stroke, and MI has proven benefit in reducing incidence of CRPS.
- One study of wrist fractures found that addition of 500 mg/day of vitamin C lowered rates of CRPS.
- There is evidence that limiting use of tourniquets, liberal regional anesthetic use, and ensuring adequate perioperative analgesia can reduce the incidence of CRPS-I.

COMMONLY ASSOCIATED CONDITIONS
- Serious injury to bone and soft tissue
- Herpes zoster
- Postherpetic neuralgia results from partial or complete damage to afferent nerve pathways.
- Pain occurs in dermatomes as a sequela of herpes zoster.
- Signal exists for patients having comorbid painful conditions or psychiatric diagnosis at increased risk of developing CPRS.

DIAGNOSIS
Unprovoked pain is the hallmark of the condition, and the diagnosis of CRPS is excluded by the existence of conditions that would otherwise account for the degree of symptoms. Budapest clinical diagnostic criteria (2,3)[C] can aid in establishing diagnosis:
- Continuing pain which is disproportionate to any inciting event
- At least one symptom in 3 of the 4 following categories:
  - Sensory: hyperalgesia and/or allodynia
  - Vasomotor: skin, temperature, color asymmetry
  - Sudomotor/edema: edema, sweating changes, or sweating asymmetry
  - Motor/trophic: decreased range of motion or motor dysfunction and/or trophic changes (hair, nail, skin)
- Must display one sign at the time of the evaluation in 2 or more of the following:
  - Sensory: hyperalgesia (to pinprick) or allodynia (to light touch, pressure, or joint movement)
  - Vasomotor: evidence of temperature, skin, color asymmetry
  - Sudomotor/edema: evidence of edema or sweating changes or asymmetry
  - Motor/trophic: decreased range of motion; motor dysfunction; or trophic changes in hair, nails, skin
- There is no other diagnosis that explains the signs and symptoms.

HISTORY
The patient commonly complains of persistent burning pain, swelling, and poor function after extremity injury. The severity of the preceding injury may vary from fracture to relatively minor trauma (3).

PHYSICAL EXAM
The affected extremity appears swollen with erythematosus, shiny skin with brittle nails and
Reduced hair. There will be limited range of motion—both active and passive.

**DIFFERENTIAL DIAGNOSIS**
- Infection
- Hypertrophic scar
- Bone fragments
- Neuroma
- CNS tumor or syrinx
- Deep vein thrombosis or thrombophlebitis
- Thoracic outlet syndrome
- Connective tissue disorder
- Factitious

**DIAGNOSTIC TESTS & INTERPRETATION**
The diagnosis of CPRS does not require any specific testing—it is a clinical diagnosis.

**Initial Tests (lab, imaging)**
- CBC
- Erythrocyte sedimentation rate (ESR)
- Plain radiographs may show patchy demineralization within 3 to 6 weeks of onset of CRPS that are more pronounced than would be seen from disuse alone.
- Three-phase bone scanning has varying sensitivity but is most accurate for support of the diagnosis when there is diffuse activity (especially on phase 3).
- Bone density

**Diagnostic Procedures/Other**
- Electromyelography (EMG) shows nerve injury with type II CRPS.
- Sudomotor function testing (resting sweat testing, resting skin temperature, quantitative sudomotor axon reflex testing; all related to increased autonomic activity of the affected limb).

**Test Interpretation**
- Partial or complete damage to afferent nerve pathways and probably reorganized central pain pathways
- Nerves most commonly involved are median and sciatic.
- Atrophy in affected muscles
- Incomplete nerve plexus lesion

**TREATMENT**

**GENERAL MEASURES**
Discourage maladaptive behaviors (pain medication seeking, secondary gain). Principal of functional restoration is a stepwise and multidisciplinary approach. Early and aggressive mobilization seems to lessen the duration.

**MEDICATION**

**First Line**
- NSAIDs recommended early in course but mixed support in literature
The following have literature support of either limited or suggestive benefit in treatment of CRPS-I:

- Corticosteroids (prednisone 30 mg/day × 2 to 12 weeks with taper) are the only class of drugs that have direct clinical trial support early in the course. A recent retrospective case review found that patients showed significant improvement with various measurable physical parameters after treatment with prednisolone (30 mg starting dose tapering by 5 mg every 3 days for a total of 3 weeks treatment) (4)[B].
- Gabapentin 600 to 1,800 mg/day for 8 weeks following diagnosis (2)[C]
- 50% DMSO cream applied to affected extremity up to 5 times daily
- N-Acetylcysteine 600 mg TID
- Bisphosphonates (alendronate) at 40 mg/day (however, optimal dose uncertain) (2)[C]
- Nifedipine 20 mg/day showed benefit early in the course of the condition

Although many have advocated the use of tricyclic antidepressants in the treatment of CRPS, there is no credible evidence of improvement of pain. They may be helpful in controlling depressive symptoms that develop with disease progression (1)[B].

ISSUES FOR REFERRAL

- After 2 months of the illness, psychological evaluation generally is indicated to identify and treat any comorbid conditions. Depressive symptoms frequently develop.
- Physical therapy and occupational therapy early for guided motor and mirror therapy (1)[B]

ADDITIONAL THERAPIES

Type I

- Physical and occupational therapy (beneficial to the overall prognosis for recovery) should be initiated early in the course of treatment.
  - “Mirror therapy” has shown good results.
  - Case reports of patients responding favorably to passive ROM treatment under sedation followed by multiple physical therapy sessions
- Transcutaneous nerve stimulation
- Psychotherapy
- Use of subdissociative (0.2 to 0.5 mg/kg) infusions of ketamine has shown some promise, but effects seem to be time limited; systemic literature review failed to find any high-quality support for ketamine treatment.

SURGERY/OTHER PROCEDURES

- Type II responds more favorably to nerve-directed treatment.
  - Sympathetic blocks
  - Cervicothoracic or lumbar sympathectomies have little data to support their use and should be used judiciously and after all other therapies have failed.
- Anesthetic blockade (chemical or surgical) of sympathetic nerve function
  - Transient relief suggests that chemical or surgical sympathectomy will be helpful.
  - Little in the way of quality clinical trials exist to support local sympathetic blockage as the gold standard of therapy.
- IV regional sympathetic block with guanethidine or reserpine by pain specialist or anesthetist
- Transcutaneous electric nerve stimulation (controversial)
- Inject myofascial painful trigger points.
- Dorsal root ganglion (DRG) stimulation higher rate of success than spinal cord stimulation in
recent comparative study; more specific target as DRG home of soma of sensory neurons
- Intrathecal analgesia
- Amputation as a last resort in severe cases, with patients reporting improved quality of life
- Single case study of topical 5% lidocaine revealed significant pain reduction and improved range of motion and function.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Vitamin C (500 mg/day) may help to prevent CRPS in those with wrist fracture (2)[C].
- Briskly rub the affected part several times per day.
- Acupuncture
- Hypnosis can be suggested.
- Relaxation training (alternate muscle relaxing and contracting)
- Biofeedback
- Whirlpool baths

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Only for proposed surgical therapy

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Weekly, to monitor progress and initiate additional modalities as needed

**PATIENT EDUCATION**
- Counsel to remain active physically.
- American RSD Hope Group: [http://www.rsdhope.org](http://www.rsdhope.org); 207-583-4589

**PROGNOSIS**
Most improve with early treatment, but symptoms may be lifelong if there is limited response to initial treatments.

**COMPLICATIONS**
- Depression
- Disability
- Opioid dependence

**REFERENCES**
ADDITIONAL READING

CODES

ICD10
- G90.52 Complex regional pain syndrome I of lower limb
- G90.523 Complex regional pain syndrome I of lower limb, bilateral
- G56.4 Causalgia of upper limb

CLINICAL PEARLS

- A pain syndrome disproportioned to injury
- Pain control and early mobility are the key to recovery.
- Avoid use of opiate analgesics.
- Use a multidisciplinary approach
CONDYLOMATA ACUMINATA
Caroline R. Campbell, MD  M. Ashleigh Brown, DO  E. James Kruse, DO

BASICS
DESCRIPTION
- Condylomata acuminata are soft, skin-colored, fleshy lesions (commonly called genital warts) that are caused by human papillomavirus (HPV):
  - Warts appear singly or in groups (a single wart is a “condyloma”; multiple warts are “condylomas” or “condylomata”); small or large; typically appear on the anogenital skin (penis, scrotum, introitus, vulva, perianal area); and may occur in the anogenital tract (vagina, cervix, rectum, urethra, anus); also conjunctival, nasal, oral, and laryngeal warts
- System(s) affected: skin/exocrine, reproductive, occasionally respiratory
- HIV considerations:
  - Treatment of external genital warts should not be different for HIV-infected persons (1).
  - Lesions may be larger or more numerous (1).
  - May not respond as well to therapy as immunocompetent persons (1)

Pediatric Considerations
- Consider sexual abuse if seen in children, although children can be infected by other means (e.g., transfer from wart on another child’s hand or prolonged latency period) (2).
- American Academy of Pediatrics recommends all school-aged children who present with lesions be evaluated for abuse and screened for other STDs (2).

Pregnancy Considerations
- Warts often grow larger during pregnancy and regress spontaneously after delivery.
- Neonatal infection is thought to occur through vertical transmission. Incidence remains controversial. Cesarean section is not absolutely indicated for maternal condylomata (3).
- Cervical infection has been found to be a risk factor for preterm birth (3).
- Few documented cases of laryngeal papillomas due to HPV transmission at the time of delivery. Although rare, the condition is life-threatening.
- HPV vaccination is contraindicated in pregnancy.
- Treatment during pregnancy is somewhat controversial but may include topical trichloroacetic acid (TCA), cryotherapy, electrocautery, or surgical excision.
- The safety of imiquimod, sinearatechins, podophylin, and podofilox during pregnancy has not been established (3).

EPIDEMIOLOGY
- HPV types 6 and 11 associated with 90% of condylomata acuminata. Types 16, 18, 31, 33, and 35 may be found in warts and may be associated with high-grade intraepithelial dysplasia in immunocompromised states such as HIV.
- Highly contagious; incubation period may be from 1 to 8 months. Initial infections may very well go unrecognized, so a “new” outbreak may be a relapse of an infection acquired years prior.
Predominant age: 15 to 30 years
Predominant sex: 1:1 male to female
Most infections are transient and clear spontaneously within 2 years.

Incidence
One study population demonstrated that from 2007 to 2010, with the introduction of HPV vaccines, the incidence of genital warts decreased 35% (from 0.94% per year to 0.61% per year) in females <21 years and decreased 19% in males <21 years.

Prevalence
Most common viral sexually transmitted infection (STI) in the United States. Most sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
Estimated 6.2 million Americans become infected with genital HPV each year.
Peak prevalence in ages 17 to 33 years
10–20% of sexually active women may be actively infected with HPV. Studies in men suggest a similar prevalence.
Pregnancy and immunosuppression favor recurrence and increased growth of lesions.

Etiology and Pathophysiology
HPV is a circular, double-stranded DNA molecule. There are >120 HPV subtypes. HPV types that cause genital warts do not cause anogenital cancers.

Risk Factors
- Usually acquired by unprotected sexual activity
  - Young adults and adolescents
  - Multiple sexual partners; short interval between meeting new sex partner and first intercourse
  - Not using protective barriers
  - Young age of commencing sexual activity
  - History of other STI
- Immunosuppression (particularly HIV)
- Cigarette smoking
- Use of oral contraceptives
- Radiation therapy

General Prevention
- Sexual abstinence or monogamy
- HPV vaccination is for prevention of HPV infections and HPV-associated cancers. This vaccine is targeted to adolescents before the period of their greatest risk for exposure to HPV. The vaccine does not treat previous infections:
  - A 2-dose schedule (0, 6 to 12 months) will have efficacy equivalent to a 3-dose schedule (0, 1 to 2, 6 months) if the HPV vaccination series is initiated before the 15th birthday (4).
  - The 9-valent HPV (9vHPV; Gardasil 9) vaccine protects against the two most common HPV serotypes (types 6 and 11, which cause most anogenital warts) and the two most cancer-promoting types (16 and 18) as well as 31, 33, 45, 52, and 58 (4).
  - Quadrivalent HPV (4vHPV) and 9vHPV vaccines (Gardasil and Gardasil 9) are licensed for use in females and males aged 9 through 45 years (5).
– The Advisory Committee on Immunization Practices (ACIP) has recommended routine vaccination at age 11 or 12 years for females since 2006 and since 2011 for males (4).

Made of condoms is partially effective, although warts may be easily spread by lesions not covered by a condom (e.g., 40% of infected men have scrotal warts).

Abstinence until treatment completed

COMMONLY ASSOCIATED CONDITIONS

- >90% of cervical cancer associated with HPV types 16, 18, 31, 33, and 35
- 60% of oropharyngeal and anogenital squamous cell carcinomas are associated with HPV.
- STIs (e.g., gonorrhea, syphilis, chlamydia), AIDS

DIAGNOSIS

HISTORY

- Explore sexual history, contraception use, and other lifestyle topics.
- Most warts are asymptomatic but symptoms include
  - Pruritus, burning, redness, pain, bleeding
  - Vaginal discharge
  - Large warts may cause obstructive symptoms in the anus (with defecation) or vaginal canal (with intercourse or childbirth).

PHYSICAL EXAM

- Lesions often have a typical rough, warty appearance with multiple fingerlike projections but may be soft, sessile, and smooth.
- Large lesions are cauliflower-like and may grow to >10 cm.
- Most common sites: penis, vaginal introitus, and perianal region
- May be seen anywhere on the anogenital epithelium or in the anogenital tract
- Warts often occur in clusters.
- Bleeding or irritation of the lesions may be noted.

DIFFERENTIAL DIAGNOSIS

- Condylomata lata (flat warts of syphilis)
- Lichen planus
- Normal sebaceous glands
- Seborrheic keratosis
- Molluscum contagiosum
- Keratomas, micropapillomatosis
- Scabies
- Crohn disease
- Skin tags
- Melanocytic nevi
- Vulvar intraepithelial neoplasia
- Squamous cell carcinoma

DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis is usually clinical, made by unaided visual examination of the lesions.
- Biopsy
Acetowhitening test: Subclinical lesions can be visualized by applying moistened gauze soaked with 5% acetic acid (vinegar) to the affected area for 5 minutes. Using a 10× hand lens or colposcope, warts appear as tiny white papules. A shiny white appearance of the skin represents foci of epithelial hyperplasia (subclinical infection), but because of low specificity, the CDC recommends against routine use of this test to screen for HPV mucosal infection.

**Initial Tests (lab, imaging)**
- Usually not required for diagnosis
- Serologic tests for syphilis may be helpful to rule out condylomata lata.
- Other testing for STIs
- Pap smear may be indicated.

**Follow-Up Tests & Special Considerations**
Because squamous cell carcinoma may resemble or coexist with condylomata, biopsy may be considered for lesions refractory to therapy.

**Diagnostic Procedures/Other**
- Biopsy with highly specialized identification techniques, such as HPV DNA detected through polymerase chain reaction, is rarely useful.
- Colposcopy, antroscopy, anoscopy, and urethroscopy may be required to detect anogenital tract lesions.
- Screening men who have sex with men (MSM) with anal Pap smears is controversial.

**TREATMENT**

**GENERAL MEASURES**
- Approximately, 30% resolve spontaneously in 4 months.
- Change therapy if no improvement after three treatments, clearance not complete after six treatments, or therapy’s duration or dosage exceeds manufacturer’s recommendations.
- Appropriate screening/counseling of partners

**MEDICATION**

**First Line**
- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- Recommendations for external genital warts, patient applied:
  - Podofilox (Condylox) (3)[A]: antimitotic action; apply 0.5% solution or gel to warts twice daily (allowing to dry) for 3 consecutive days at home followed by 4 days of no therapy; may repeat up to 4 total cycles; maximum of 0.5 mL/day or area <10 cm²
  - Imiquimod (Aldara) (3)[A]: immune enhancer; self-treatment with a 5% cream applied once daily at bedtime 3 times weekly until warts resolve for up to 16 weeks. Wash off with soap and water 6 to 10 hours after application. Imiquimod has been noted to weaken condoms and diaphragms; therefore, patients should refrain from sexual contact while the cream is on the skin.
  - Sinecatechins (Veregen): immune enhancer and antioxidant, extract from green tea; apply a 0.5-cm strand of ointment 3 times daily for up to 16 weeks. Do not wash off after.
- Recommendations for external genital warts, provider applied:
– Cryotherapy: liquid nitrogen applied to warts for two bursts of approximately 10 seconds (or whatever time is needed to freeze the wart without extension significantly deep or lateral to the wart) with thawing in between; usually requires 2 to 3 weekly sessions (3)[A]
– Podophyllin 10–25% in tincture of benzoin. Apply directly to warts, air-dry in office before coming into contact with clothes. Wash off in 1 to 4 hours. Repeat every 7 days in office until gone (3)[A].
– TCA: 80% solution. Apply only to warts; powder/talc to remove unreacted acid. Repeat in office at weekly intervals; ideal for isolated lesions in pregnancy (3)[A]

Recommendations for exophytic cervical warts: biopsy to exclude high-grade squamous intraepithelial lesion (SIL) (3)[A]
Recommendations for vaginal warts: cryotherapy or TCA or bichloroacetic acid (BCA) 80–90% (3)[A]
Recommendations for urethral meatus warts: cryotherapy or podophyllin 10–25% in compound tincture of benzoin (3)[A]
Recommendations for anal warts: cryotherapy, TCA or BCA 80–90%, or surgery; specialty consultation for intra-anal warts (3)[A]

Pregnancy Considerations
Cryotherapy, surgery, or TCA; medications contraindicated in pregnancy: podophyllin, podophyllotoxin, sinecatechins, interferon, and imiquimod (3)[C]

Second Line
Intralesional interferon, photodynamic therapy, topical cidofovir (3)[A]

SURGERY/OTHER PROCEDURES
– Larger warts may require surgical excision, laser treatment, or electrocoagulation (including infrared therapy):
  – Precaution: Laser treatment may create smoke plumes that contain HPV. CDC recommendation is for the use of a smoke evacuator no <2 inches from the surgical site. Masks are recommended; N95 the most efficacious (6)
– Intraurethral, external (penile and perianal), anal, and oral lesions can be treated with fulgurating CO₂ laser. Oral or external penile/perianal lesions can also be treated with electrocautery or surgery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
No restrictions, except for sexual contact

Patient Monitoring
– Patients should be seen every 1 to 2 weeks until lesions resolve.
– Patients should follow up 3 months after completion of treatment.
– Persistent warts require biopsy.
– Sexual partners require monitoring.

PATIENT EDUCATION
– Provide information on HPV, STI prevention, and condom use.
Explain to patients that it is difficult to know how or when a person acquired an HPV infection; a diagnosis in one partner does not prove sexual infidelity in the other partner. Emphasize the need for women to follow recommendations for regular Pap smears.

PROGNOSIS
- Asymptomatic infection persists indefinitely.
- Treatment has not clearly been shown to decrease transmissible infectivity.
- Warts may clear with treatment or resolve spontaneously. However, recurrences are frequent, particularly in the first 3 months, and may necessitate repeated treatments.

COMPLICATIONS
- Cervical dysplasia (probably does not occur with type 6 or 11, which cause most warts)
- Malignant change: Progression of condylomata to cancer rarely, if ever, occurs, although squamous cell carcinoma may coexist in larger warts.
- Urethral, vaginal, or anal obstruction from treatment
- The prevalence of high-grade dysplasia and cancer in anal canal is higher in HIV-positive than in HIV-negative patients, probably because of increased HPV activity.

REFERENCES

ADDITIONAL READING

CODES

ICD10
A63.0 Anogenital (venereal) warts

CLINICAL PEARLS

- Condylomata acuminata are soft, skin-colored, fleshy lesions caused by HPV subtypes 6, 11, 16, 18, 31, 33, and 35.
- The majority of sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- 9vHPV vaccine is effective in preventing HPV infection, particularly if administered prior to the onset of engaging in sexual activity. Gardasil is approved and recommended for use in males and females aged 9 to 45 years.
CONJUNCTIVITIS, ACUTE
Frances Y. Wu, MD, FAAFP

BASICS

DESCRIPTION
- Inflammation of the bulbar and/or palpebral conjunctiva of <4 weeks’ duration
- System(s) affected: nervous, skin/exocrine
- Synonym(s): pink eye

Geriatric Considerations
- Suspect autoimmune, systemic, or irritative process.
- If purulent, risk of bacterial cause increases with age, with age >65 years and bilateral lid adherence risk for bacterial infection is >70%.

Pediatric Considerations
- Neonatal conjunctivitis may be gonococcal, chlamydial, irritative, or related to dacryocystitis.
- Pediatric ER study; 78% positive bacterial culture, mostly Haemophilus influenzae; 13% no growth; other studies showed >50% adenovirus.
- Children <5 years 7 times more likely have bacterial involvement than older children or mid aged adults.
- Despite lack of evidence, daycare regulations may require a child with presumed conjunctivitis to be treated with a topical antibiotic before returning (1)[A].

EPIDEMIOLOGY
- Predominant age
  - Pediatric: viral, bacterial
  - Adult: viral, bacterial, allergic
- Predominant sex: male = female

Incidence
1–2% of ambulatory office visits, up to 3% of ER visits

ETIOLOGY AND PATHOPHYSIOLOGY
- Viral
  - Adenovirus (common cold), coxsackievirus (implicated in recent hemorrhagic conjunctivitis epidemics in Asia and Middle East)
  - Enterovirus (acute hemorrhagic conjunctivitis)
  - Herpes simplex
  - Herpes zoster or varicella
  - Measles, mumps, or influenza
- Bacterial
  - Staphylococcus aureus or Staphylococcus epidermidis
  - Streptococcus pneumoniae
  - H. influenzae (children)
  - Pseudomonas spp. or anaerobes (contact lens users)
Acanthamoeba-contaminated contact lens solution may cause keratitis (rare; ~30 cases per year in United States).

Neisseria gonorrhoeae and Neisseria meningitidis

Chlamydia trachomatis: gradual onset 1 to 4 weeks

Escherichia coli neonatal conjunctivitis reported rarely, and tuberculosis reported in treatment resistant cases

- **Allergic**
  - Hay fever, seasonal allergies, atopy

- **Nonspecific**
  - Irritative: topical medications, wind, dry eye, UV light exposure, smoke
  - Autoimmune: Sjögren syndrome, pemphigoid, Wegener granulomatosis
  - Rare: Rickettsia, fungal, parasitic, tuberculosis, syphilis, Kawasaki disease, chikungunya, Graves disease, gout, carcinoid, sarcoid, psoriasis, Stevens-Johnson syndrome, Reiter syndrome

**RISK FACTORS**

- History of contact with infected persons
- Sexually transmitted disease (STD) contact: gonococcal, chlamydial, syphilitic, or herpes
- Contact lenses: pseudomonal or acanthamoeba keratitis
- Epidemic bacterial (streptococcal) conjunctivitis reported in school settings

**GENERAL PREVENTION**

- Wash hands frequently.
- Eyedropper technique: while eye is closed and head back, several drops over nasal canthus and then open eyes to allow liquid to enter. Never touch tip of dropper to skin or eye.

**COMMONLY ASSOCIATED CONDITIONS**

- Viral infection (e.g., common cold)
- Possible sexually transmitted infection

**DIAGNOSIS**

**HISTORY**

**ALERT**

Red flag: Any decrease in visual acuity is not consistent with conjunctivitis alone; must document normal vision for diagnosis of isolated conjunctivitis

- **Viral:** contact or travel
  - May start with one eye and then both
  - If herpetic, recurrences or vesicles on skin
- **Bacterial:** difficult to distinguish from viral, unless contact lens user. Assume bacterial in contact lens wearer unless cultures are negative. If recent STD, suspect chlamydia or gonococcus.
- **Allergic:** itching, atopy, seasonal, dander
- **Irritative:** feels dry, exposure to wind, tear-film deficit may persist 30 days after acute conjunctivitis, chemicals, or drug: atropine, aminoglycosides, iodide, phenylephrine,
antivirals, bisphosphonates, retinoids, topiramate, chamomile, COX-2 inhibitors

Foreign body: Redness may persist 24 hours after removal.

PHYSICAL EXAM

- General: common to all types of conjunctivitis
  - Red eye, conjunctival injection
  - Foreign body sensation
  - Eyelid sticking or crusting, discharge
  - Normal visual acuity and pupillary reactivity
- Viral
  - Palpable preauricular lymphadenopathy may be present.
  - Hemorrhagic coxsackievirus-related epidemics were reported.
  - Severe viral: herpes simplex or zoster:
    - Burning sensation, rarely itching
    - Unilateral, herpetic skin vesicles in zoster
    - Palpable preauricular node
- Bacterial (non-STD): may be epidemic
  - Mild pruritus, discharge mild to heavy
  - Conjunctival chemosis/edema
  - If contact lens user, must rule out pseudomonal (or other bacterial) keratitis
- Bacterial: gonococcal (or meningococcal) hyperacute infection
  - Rapid onset 12 to 24 hours
  - Severe purulent discharge
  - Chemosis/conjunctival/eyelid edema
  - Rapid growth of superior corneal ulceration
  - Preauricular adenopathy
  - Signs of STDs (chlamydia, GC, HIV, etc.)
- Allergic
  - Itching predominant, chemosis, edema
  - Seasonal or dander allergies
- Nonspecific irritative
  - Dry eyes, intermittent redness, chemical/drug exposure
  - Foreign body: may have redness and discharge 24 hours after removal
- Must document normal visual acuity
- Cornea should be clear and without fluorescein uptake. Cloudy or ulcerated cornea signifies keratitis; consult ophthalmologist.
- Recommend fluorescein exam: Evert lid to inspect for foreign bodies.
- Skin: Look for herpetic vesicles, nits on lashes (lice), scaliness (seborrhea), or styes.
- Limbal flush at corneal margin if uveitis
- If pupil is irregular (i.e., penetrating foreign body), emergent referral is warranted.
- Discharge but no conjunctival injection: blepharitis

DIFFERENTIAL DIAGNOSIS

- Uveitis (iritis, iridocyclitis, choroiditis): limbal flush (red band at corneal margin), hazy anterior chamber, and decreased visual acuity
- Penetrating ocular trauma: emergently hospitalize
- Acute glaucoma (emergency): headache, corneal clouding, poor visual acuity
**Corneal ulcer, keratitis, or foreign body:** lesions or tear-film deficits on fluorescein exam
- Dacryocystitis: tenderness and swelling over tear sac (below medial canthus)
- Scleritis and episcleritis: red injected vessels radially oriented, sectoral (pie wedge), nodularity of sclera
- Pingueculitis: inflammation of a yellow nodular or wedge-like area of chronic conjunctival degeneration (pinguecula)
- Ophthalmia neonatorum: neonates in the first 2 days of life (gonococcal; 5 to 12 days of life): chlamydial, herpes simplex virus (HSV), very rare Neisseria meningitides. Consider specialty consultation for required systemic therapy; rare report of E. coli found on culture
- Blepharitis: Lid margins are inflamed producing itching, scale, or discharge but no conjunctival injection.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Usually not needed initially for most common causes
- Culture swab if STD is suspected, very severe symptoms, patient is a contact lens user, or if resistant to prior treatment.
- Viral swab (10-minute test) for adenovirus is costly, requires six passes to acquire sample, and may not be tolerated by children.

**Diagnostic Procedures/Other**
- Fluorescein exam for corneal ulcer or abrasion
- Remove small, superficial foreign bodies with irrigation or moistened swab.
- Refer cases of prolonged symptoms to confirm diagnosis and exclude need for biopsy.

**TREATMENT**

**GENERAL MEASURES**
- Viral conjunctivitis does not require antibiotics and resolves spontaneously.
- Clean external eyelid with wet cloth up to QID.
- Stop use of contact lenses while eye is red.
- Eye patching is not beneficial.

**MEDICATION**

**First Line**
- Viral (nonherpetic)
  - Artificial tears for symptomatic relief
  - Vasoconstrictor/antihistamine (e.g., naphazoline/pheniramine) QID for severe itching
  - May consider topical antibiotic (see bacterial below) if return to daycare requires treatment
- Viral (herpetic) (ophthalmology consultation)
  - Ganciclovir gel: 0.15%, 5 times per day for 7 days (2)[B]
  - Acyclovir: PO 400 mg 5 times per day for HSV; 800 mg for zoster for 7 days
- Bacterial (nonsexually transmitted): 3 days of cool compresses before starting antibiotic is associated with no adverse effects and reduces unnecessary antibiotic use.
  - After 3 days, consider topical antibiotics (NNT 7 at day 6) (immediate antibiotics shortened course by only 3 days in children): Bacitracin ophthalmic ointment: Apply 3 to 4 times per day for 5 to 7 days.
- Polymyxin B-trimethoprim solution 1 gtt 6 times per day for 5 to 7 days
- Erythromycin ophthalmic ointment: 1/2 inch 2 to 4 times per day for 5 days
- Sodium sulfacetamide (Bleph-10) (10% solution): 2 drops q4h (while awake) for 5 days
- Tobramycin or gentamicin: 0.3% ophthalmic drops/ointment q4h (drops) to q8h (ointment) for 7 days

**Bacterial (gonococcal)**
- Neonates: Hospitalize for IV therapy.
- Adults: ceftriaxone: 1 g IM as single dose and topical bacitracin ophthalmic ointment 1/2 inch QID. Neonates 25 to 50 mg/kg IV or IM, not to exceed 125 mg, as a single dose. Chlamydia in neonates requires oral erythromycin: 50 mg/kg/day divided q6h PO for 14 days, max 3 g/day.

**Allergic and atopic over-the-counter (OTC) medications are efficacious, no evidence favoring one over another, but cost ranges from $15 to $300 (3)[A].**
- Ketotifen (Zaditor, Alaway, and other generics OTC): 0.25% 1 drop 2 times per day
- Ketorolac (Acular): 0.1% 1 drop 4 times per day
- Cetirizine (Zerviate): 24% 1 drop 2 times per day
- Olopatadine (Pataday, Patanol): 0.1% 1 drop 2 times per day or 0.2% 1 drop daily
- Cromolyn (Opticrom): 4% 1 drop 4 times per day
- Azelastine (Astelin): 0.05% 1 drop 2 times per day
- Nedocromil (Alocril): 2% 1 drop 2 times per day
- Alcaftadine (Lastacaft): 0.25% 1 drop daily
- Emedastine (Emadine): 0.05% 1 drop 2 times per day
- Epinastine (Elestat): 0.05% 2 times per day
- Bepotastine (Bepreve): 1.5% 1 drop 2 times per day
- Lodoxamide tromethamine (Alomide): 0.1% 1 drop 4 times per day
- Oral non-sedating antihistamines (cetirizine [Zyrtec] 10 mg/day, fexofenadine [Allegra] 60 mg BID, etc.) may treat nasal symptoms but cause ocular drying; oral antihistamine (e.g., diphenhydramine 25 mg TID) in severe cases of itching

**Contraindications:** steroids not beneficial in treatment of bacterial keratitis (4)[A]. Topical immune modulators (tacrolimus, cyclosporine) should be reserved for specialist use only in the most difficult cases.

**Precautions**
- Do not allow dropper to touch the eye.
- Case reports of eye irritation from gentamicin in infants, moxifloxacin in adults, sulfacetamide in allergic individuals
- Vasoconstrictor/antihistamine: rebound vasodilation after prolonged use

**Second Line**

**Viral and allergic:** numerous OTC products

**Bacterial:** second line (quinolones used as postoperative or for known resistant organisms)
- Ofloxacin: 0.3% 1 gtt QID for 7 days
- Ciprofloxacin: 0.3% 1 gtt QID for 7 days
- Levofloxacin: 0.3% 1 gtt QID for 7 days
- Gatifloxacin: 0.3% 1 gtt TID for 7 days
- Moxifloxacin: 0.5% 1 gtt TID for 7 days
- Besifloxacin: 0.6% 1 gtt TID for 7 days
- Azithromycin: 1.5% BID for 3 days
ISSUES FOR REFERRAL
- Refer to ophthalmology for any significantly decreased visual acuity, herpetic keratitis, or contact lens–related conjunctivitis or immunocompromised (HIV).
- Refer for symptoms or worsening over 7 days (concern for severe adenoviral keratitis) (5).

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Usually benign and self-limited; saline flushes, cool compresses, and similar treatments help.
- Mandarin orange yogurt showed improvement over 2 weeks for allergic conjunctivitis in a small study.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Acute gonococcal conjunctivitis (or very rare case of meningococcal conjunctivitis) requires inpatient treatment with ceftriaxone 50 mg/kg IV everyday (pediatric), 1 g IM for one (adult) along with ophthalmologic consultation.
- Admission criteria/initial stabilization
  - Penetrating ocular trauma, gonococcal conjunctivitis

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- If not resolved within 5 to 7 days, reconsider diagnosis or consult specialist; some epidemic keratoconjunctivitis and other adenoviral conjunctivitis typically last 1 to 2 weeks.
- Children may be excluded from school until eye is no longer red, depending on school policy. Allergic conjunctivitis should return to school with doctor’s note.

PATIENT EDUCATION
- No contacts until eyes are fully healed (~1 week).
- Discard current contacts.
- Discard eye makeup, especially mascara.
- Cool, moist compresses can ease irritation and itch.

PROGNOSIS
- Viral: 5 to 10 days of symptoms for pharyngitis with conjunctivitis, 2 weeks with adenovirus
- Herpes simplex: 2 to 3 weeks of symptoms
- Most common bacterial—H. influenzae, Staphylococcus, Streptococcus: self-limited; 74–80% resolution within 7 days, whether treated or not

COMPLICATIONS
- Corneal scars with herpes simplex
- Lid scars or entropion with varicella zoster and chlamydia
- Corneal ulcers or perforation, very rapid with gonococcal
- Hypopyon: pus in anterior chamber
- Chlamydial neonatal (ophthalmic): could have concomitant pneumonia
- Otitis media may follow H. influenzae conjunctivitis.
- Very rarely N. meningitidis conjunctivitis may be followed by meningitis.

- Algorithm: Eye Pain

CODES

ICD10

- H10.30 Unspecified acute conjunctivitis, unspecified eye
- H10.33 Unspecified acute conjunctivitis, bilateral
- H10.32 Unspecified acute conjunctivitis, left eye

CLINICAL PEARLS

- Conjunctivitis does not cause decreased acuity or photophobia. If visual acuity is decreased, consider more serious ophthalmic disorders.
- Culture discharge in all contact lens wearer. Consider referral and discard current lenses until eyes are fully healed.
- Antibiotics are of no value in viral conjunctivitis (most cases of infectious conjunctivitis).
- Cool compresses for 3 days before using any antibiotic is appropriate for treating conjunctivitis in healthy adults and children >1 month.
CONSTIPATION
S. Mimi Mukherjee, PharmD, BCPS, CDE ● Sandra Marwill, MD, MPH

BASICS
Unsatisfactory defecation characterized by infrequent stools, difficult stool passage, or both. Characteristics include <3 bowel movements a week, hard stools, excessive straining, prolonged time spent on the toilet, a sense of incomplete evacuation, and abdominal discomfort/bloating.

DESCRIPTION
- System(s) affected: gastrointestinal (GI)
- Synonym(s): obstipation

Geriatric Considerations
Colorectal neoplasms may be associated with constipation. Consider new-onset constipation after age 50 years a “red flag.” Use warm water enemas (instead of sodium phosphate enemas) for impaction in geriatric patients. Sodium phosphate enemas have been associated with fatalities and severe electrolyte disturbances (1).

Pediatric Considerations
Consider Hirschsprung disease (absence of colonic ganglion cells) in cases of pediatric constipation. Hirschsprung disease accounts for 25% of all newborn intestinal obstructions and can present as milder cases diagnosed in older children with chronic constipation, abdominal distension, and decreased growth. Hirschsprung has a 5:1 male-to-female ratio and is associated with inherited conditions (e.g., Down syndrome).

Pregnancy Considerations
Avoid misoprostol.

EPIDEMIOLOGY
- More pronounced in children and elderly
- Predominant sex: female > male (2:1)
- Nonwhites > whites

Incidence
- 5 million office visits annually
- 100,000 hospitalizations

Prevalence
- 16% of adults >18 years, rising to 33% of adults >60 years of age
- 3% of pediatric visits relate to constipation.

ETIOLOGY AND PATHOPHYSIOLOGY
- As food leaves the stomach, the ileocecal valve relaxes (gastroileal reflex), and chyme enters the colon (1 to 2 L/day) from the small intestine. In the colon, sodium is actively absorbed in exchange for potassium and bicarbonate. Water follows the osmotic gradient. Peristaltic
contractions move chyme through the colon into the rectum. Chyme is converted into feces (200 to 250 mL).

- Normal transit time is 4 hours to reach the cecum and 12 hours to reach the distal colon.
- Defecation reflexively follows as stool reaches the rectal vault. This reflex can be inhibited by voluntarily contracting the external sphincter or facilitated by straining to contract the abdominal muscles while voluntarily relaxing the anal sphincter. Rectal distention initiates the defecation reflex. The urge to defecate occurs with an increase in rectal pressure. Distention of the stomach also initiates rectal contractions and a desire to defecate (gastrocolic reflex).
- Primary and secondary defecation disorders result from delay in colonic transit, altered rectal motor activity, and structural or functional problems with pelvic floor muscles (including paradoxical contractions, diminished sphincter relaxation, and/or poor propulsion).

**Genetics**
Unknown but may be familial

**RISK FACTORS**
- Very young and very old
- Polypharmacy
- Sedentary lifestyle or condition
- Improper diet and inadequate fluid intake

**GENERAL PREVENTION**
High-fiber diet, adequate fluids, exercise, and training to “obey the urge” to defecate

**COMMONLY ASSOCIATED CONDITIONS**
- General debilitation (disease or aging)
- Dehydration
- Hypothyroidism
- Hypokalemia
- Hypercalcemia
- Nursing home resident

**DIAGNOSIS**

**ALERT**
Red flags:

- New onset after age of 50 years
- Hematochezia/melena
- Unintentional weight loss
- Family history of colon cancer
- Anemia
- Neurologic defects

**HISTORY**
- Assess onset of symptoms, number of bowel movements per week, straining, completeness of evacuation, and use of manual manipulation.
- Identify red flags; evaluate diet, lifestyle, prescription, and OTC medication use; identify
reversible causes; ask about history of sexual abuse, opioid use.
- Bristol Stool Form Scale—seven categories of consistency (2)
- A diary of dietary intake and bowel patterns helps to measure treatment response.
- Rome III criteria:
  - At least two of the following for 12 weeks in the previous 6 months:
    - <3 stools per week
    - Straining at least 1/4 of the time
    - Hard stools at least 1/4 of time
    - Need for manual assist at least 1/4 of time
    - Sense of incomplete evacuation at least 1/4 of time
    - Sense of anorectal blockade at least 1/4 of time
  - Loose stools rarely seen without use of laxatives
  - Frequent constipation but does not meet irritable bowel syndrome (IBS) criteria
  - Although there can be overlap, the history of primary constipation differs from constipation-predominant IBS.
    - In primary constipation, pain and bloating are relieved by adequate defecation. In IBS, pain and bloating predominate and are not readily relieved by defecation.
- Bowel Function Index—for opioid-induced constipation (OIC) score of 0 to 100, mean of three variables; ease of defecation, completeness of emptying, patient’s rating of constipation severity

PHYSICAL EXAM
- Vital signs
- Abdominal exam, previous surgical scars, hypoactive bowel sounds, tenderness, and masses
- Gynecologic exam: Evaluate for masses and rectocele.
- Digital rectal exam: Evaluate for masses, pain, stool, fissures, and hemorrhoids; assess sphincter tone.
- Neurologic exam

DIFFERENTIAL DIAGNOSIS
- Primary constipation (primary problem is within the GI tract) has four subtypes.
  - Normal colonic transit time most common subtype; can be difficult to differentiate from constipation-predominant IBS
  - Slow colonic transit time
  - Pelvic floor/anal sphincter dysfunction
  - Combination pelvic floor/anal sphincter dysfunction and slow transit
- Secondary constipation (outside the GI tract)
  - Endocrine dysfunction (diabetes mellitus, hypothyroid)
  - Metabolic disorder (increased calcium, decreased potassium)
  - Mechanical (obstruction, rectocele)
  - Pregnancy
  - Neurologic disorders (Hirschsprung, multiple sclerosis, spinal cord injuries, Parkinson disease)
- Congenital
  - Hirschsprung disease/syndrome
  - Hypoganglionosis
  - Congenital dilation of the colon
– Small left colon syndrome
• Medication effect
  – Opioids
  – Antidepressants
  – Antipsychotics
  – Antacids (calcium, aluminum)
  – Nondihydropyridine calcium channel blockers, especially verapamil
  – Iron and multivitamins with iron
  – Diuretics
  – Overuse of antidiarrheal medications

DIAGNOSTIC TESTS & INTERPRETATION
Identify red flags, secondary causes, and reversible conditions. If none present, go to first-line treatment.

Initial Tests (lab, imaging)
• CBC to screen for iron deficiency anemia
• Consider tox screen if illicit opioid use is suspected.
• Calcium, glucose, and thyroid function testing (TSH) based on history and exam. If red flags are present, refer for sigmoid/colonoscopy.

Follow-Up Tests & Special Considerations
For patients with pelvic floor dysfunction or exam abnormalities (e.g., rectocele) and/or patients who are refractory to initial treatment, refer to an experienced subspecialist. A physical therapist experienced in biofeedback can also be very helpful.

Diagnostic Procedures/Other
• Anorectal manometry (ARM)
• Balloon expulsion testing (BET)
• Scintigraphy
• MRI
• Defecography
• Colonic marker studies

Test Interpretation
• ARM and BET recommended for all refractory cases
• If ARM and BET are negative, scintigraphy may help evaluate transit time.
• Consider biofeedback prior to scintigraphy.

TREATMENT
Address immediate concerns:
• Bloating/discomfort/straining: osmotic agents
• Postoperative, after childbirth, hemorrhoids, fissures: stool softener to aid defecation
• If impacted: manual disimpaction and then treat any underlying conditions

GENERAL MEASURES
In patients with no known secondary causes, conservative nonpharmacologic treatment is
Eliminate medications that cause constipation.
Increase fluid intake.
Increase soluble fiber in diet.
Encourage regular defecation attempts after eating.
Regular exercise
Enemas if other methods fail (avoid sodium phosphate enemas in geriatric patients) (1)[B]

MEDICATION
Nonprescription medications are first line. If patient goals are not reached, advance to prescription medications.

First Line
Bulking agents (accompanied by adequate fluids):
- Hydrophilic colloids (bulk-forming agents)
  - Psyllium (Konsyl, Metamucil, Perdiem Fiber): 1 tbsp in 8-oz liquid PO daily up to TID
  - Methylcellulose (Citrucel): 1 tbsp in 8-oz liquid PO daily up to TID
  - Polycarbophil (Mitrolan, FiberCon): 2 caplets with 8-oz liquid PO up to QID
- Stool softeners
  - Docusate sodium (Colace): 50 to 100 mg PO TID
- Osmotic laxatives
  - Polyethylene glycol (PEG) (MiraLAX) 17 g/day PO dissolved in 4 to 8 oz of beverage (current evidence shows PEG to be superior to lactulose) (3)[B]
  - Lactulose (Chronulac, Enulose) 15 to 60 mL PO QHS (flatulence, bloating, cramping)
  - Sorbitol: 15 to 60 mL PO QHS (as effective as lactulose)
  - Magnesium salts (milk of magnesia): 15 to 30 mL PO once daily; avoid in renal insufficiency.

Second Line
- Stimulants (irritate bowel, causing muscle contraction; usually combined with a softener; work in 8 to 12 hours)
  - Senna/docusate (Senokot-S, Ex-lax, Peri-Colace): 1 to 2 tablets or 15 to 30 mL PO at bedtime
  - Bisacodyl (Dulcolax, Correctol): 1 to 3 tablets PO daily
- Lubricants (soften stool and facilitate passage of the feces by its lubricating oily effects)
  - Mineral oil (15 to 45 mL/day)
  - Short-term use only; can bind fat-soluble vitamins, with the potential for deficiencies; may similarly decrease absorption of some drugs
  - Avoid in those at risk for aspiration (lipoid pneumonia).
- Suppositories
  - Osmotic: sodium phosphate
  - Lubricant: glycerin
  - Stimulatory: bisacodyl
  - Enemas: saline (Fleet enema)
- Lubiprostone (Amitiza): a selective chloride channel activator; 24 μg PO BID
- Prucalopride (Motegrity): a serotonin-4 receptor antagonist; adult dose: 2 mg PO once daily, for CrCl < 30 use 1 mg once daily; increased incidence of suicidal ideation reported in clinical
trials

- Guanylate cyclase-C agonists (adult use only)
  - Linaclotide (Linzess): dose: 145 μg PO once daily; can use lower dose 72 μg once daily
  - Plecanatide (Trulance): dose: 3 mg PO once daily

- Peripherally acting μ-opioid receptor antagonists, indicated for OIC. Try laxatives first; lubiprostone also approved for OIC
  - Methylnaltrexone (Relistor): dose: 38 to <62 kg: 8 mg; 62 to 114 kg: 12 mg SC every other day PRN
  - Naloxegol (Movantik): dose: 12.5 to 25.0 mg PO daily; discontinue other laxatives for 3 days when initiating naloxegol; avoid in patients on strong CYP3A4 inhibitors due to increased naloxegol levels and risk of opioid withdrawal.
  - Naldemedine (Symproic): dose: 0.2 mg PO daily; monitor for opioid withdrawal in patients on strong CYP3A4 inhibitors or P-gp inhibitors.

- Prokinetic agents (partial 5-HT4 agonists) have been withdrawn due to cardiac side effects; only available via IND protocols: tegaserod (Zelnorm), cisapride (Propulsid)

- Other agents not approved by the FDA:
  - Misoprostol (Cytotec): a prostaglandin that increases colonic motility
  - Colchicine: neurogenic stimulation to increase colonic motility

ADDITIONAL THERAPIES

- Other nonpharmacologic therapies include biofeedback, a first-line recommendation for patients with refractory constipation due to functional conditions involving dyssynergic defecation or inadequate propulsive force.
- Behavior therapy
  - Acupuncture: initial randomized trial effective at 20 weeks; longer term trials needed

SURGERY/OTHER PROCEDURES

Surgery rarely indicated; sometimes required for anatomic findings (rectocele or enterocoele)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Toxic megacolon
- Manual disimpaction occasionally required in chronic refractory cases

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Encourage exercise and physical activity.

Patient Monitoring

If functional constipation persists, revisit secondary causes.

DIET

Increase soluble fiber (bloating and gas can be problematic with insoluble fiber):
- Gradually increase intake to 25 g/day over a 6-week period.
- Oat bran (hard outer layer of cereal grains)
- Peas; onions; lentils; beans; seeds; nuts; and fruits, including bananas, apples, and strawberries
- Encourage liberal intake of fluids.
PATIENT EDUCATION
- Occasional mild constipation is normal.
- Bowel training: The best time to move bowels is in the morning, after eating breakfast, when the normal bowel transit and defecation reflexes are functioning.

PROGNOSIS
- Occasional constipation responds well to simple measures.
- Habitual constipation can be a lifelong nuisance.
- Patients with neurologic compromise can suffer from obstipation, impaction, and toxic megacolon.
- No evidence for laxative dependence or harm from stimulant use; melanosis coli may develop but is a benign condition.

COMPLICATIONS
- Volvulus
- Toxic megacolon
- Acquired megacolon in severe, long-standing cases
- Fluid and electrolyte depletion: laxative abuse
- Rectal ulceration (stercoral ulcer) related to recurrent fecal impaction
- Anal fissures

REFERENCES

ADDITIONAL READING

CODES

ICD10
- K59.00 Constipation, unspecified
K59.01 Slow transit constipation
K59.09 Other constipation

**CLINICAL PEARLS**

- Constipation (especially with normal transit time) is common. Reversible risk factors include inadequate hydration, sedentary lifestyle, poor dietary habits, and medication side effects.
- Red flags: onset >50 years, hematochezia/melena, unintentional weight loss, anemia, neurologic defects
- Osmotic agents (PEG) are the most clinically effective.
CONTRACEPTION
Gena M. Grospe, DO ● Roxanne Smith, MD, MPH

BASICS

DESCRIPTION
- Medications or procedures that control timing of pregnancies and prevent unintended pregnancies
- Contraception options are divided into two major categories: hormonal and nonhormonal.
- The most effective methods of contraception are vasectomy, female sterilization, and the long-acting reversible contraceptives (LARCs).

EPIDEMIOLOGY

Incidence
- The estimated prevalence of contraception use among women age 15 to 44 years is 61% in the United States (1).
- 49% of all pregnancies in the United States are unintended, and half of these occur in women using a form of reversible contraception.
- 43% of all unintended pregnancies in the United States result in termination.
- The most commonly used methods were the pill (16.0%), female sterilization (15.5%), condoms (9.4%), and LARCs (7.2%).

RISK FACTORS
Unintended pregnancy: higher rates among women ages 18 to 24 and >40 years, unmarried/cohabitating women, women with less than a college education, and minority women.

DIAGNOSIS

HISTORY
- Review past medical, family, social, obstetric, and gynecologic histories including menstrual history, prior experience with contraceptives, and prior sexually transmitted diseases (STDs).
- Screen for hypertension.
- In family history of thrombophilia, testing can be considered before initiation of estrogen-containing contraception, especially if specific defect is known.
- Contraindications: See CDC medical eligibility criteria (MEC) (2).
  - Estrogen-progestin contraceptives
    o Absolute: age ≥35 years and smoking ≥15 cigarettes per day, <21 days postpartum, SBP ≥160 mm Hg or DBP ≥100 mm Hg, multiple CAD risk factors, current/prior venous thromboembolism (VTE), thrombophilia, long-standing/complicated diabetes, ischemic heart disease, stroke, complicated valvular disease, systemic lupus, migraine with aura, breast cancer, severe cirrhosis, solid organ transplant, hepatocellular adenoma, or malignant hepatoma
    o Relative: age ≥35 years and smoking <15 cigarettes per day, breastfeeding <42 days postpartum, SBP 140 to 159 mm Hg or DBP 90 to 99 mm Hg (or well-controlled on
medications), symptomatic cholelithiasis, certain anticonvulsants, bariatric surgery, migraines without aura but ≥35 years, or breast cancer history in remission >5 years

- Progestin-only (pill/Depo/implant)
  - Absolute: current breast cancer
  - Relative: bariatric surgery, ischemic heart disease, history of stroke, lupus, migraine with aura, severe cirrhosis, certain anticonvulsants, hepatocellular adenoma, or malignant hepatoma

- Levonorgestrel—intrauterine device (IUD)
  - Absolute: immediate postseptic abortion, postpartum sepsis, gestational trophoblastic disease, current breast cancer, distorted uterine cavity. The following are absolute contraindications for initiation but not continuation of method: cervical/endometrial cancer, unexplained vaginal bleeding, current pelvic inflammatory disease (PID), purulent cervicitis, gonorrhea/chlamydia infection, pelvic tuberculosis (TB).
  - Relative: ischemic heart disease, lupus, severe cirrhosis, hepatocellular adenoma or malignant hepatoma, increased risk of STDs, solid organ transplant

- IUD–copper (“ParaGard”)
  - Absolute: same as levonorgestrel-IUD except use in cancer of breast, possibly cervix OK
  - Relative: severe thrombocytopenia, increased risk of STDs, solid organ transplant

**DIAGNOSTIC TESTS & INTERPRETATION**

- A negative pregnancy test (urine or serum) is advised prior to initiating contraception.
- Consider testing for gonorrhea and chlamydia prior to IUD insertion especially if age <25 years or multiple sexual partners. Testing can be done at time of insertion if symptomatic infection is ruled out.
- Perform Pap smear if otherwise indicated.

**TREATMENT**

**GENERAL MEASURES**

- Method(s) should be selected based on patient preference, effectiveness, need for STD prevention, side effects, and contraindications.
- General categories included hormonal and nonhormonal methods.
  - Nonhormonal methods include condoms, diaphragm, cervical cap, copper IUD, vasectomy, female sterilization, fertility awareness, sponge, spermicides, and abstinence.
  - Hormonal methods include oral contraceptives, patch, ring, injectables, IUDs, and implants.

**MEDICATION**

- Estrogen-progestin contraceptives
  - Mechanism of action: suppression of ovulation, thickening cervical mucus, and endometrial changes that interfere with transport of sperm to egg and with implantation
  - Efficacy: failure rate of about 9% with typical use and 0.3% with perfect use at 1 year (3)
  - Side effects: nausea, bloating, headaches, mastalgia, depression, acne, and hirsutism
  - Side effect management: Breakthrough bleeding is usually self-limiting after 3 months; if persists, change pill. Amenorrhea: Rule out pregnancy.
  - Combined oral contraceptives (COCs): pill
    - All COCs contain the same type of estrogen (ethinyl estradiol) but differ in the amount of
estrogen (range of 10 to 50 μg) and the type of progestin.

- VTE risk is highest with those containing 50 μg estrogen. Newer 3rd-generation progestins (norgestimate and desogestrel) are less androgenic but have increased rate of VTE (4).
- Start with a pill that contains an average amount of estrogen (30 to 35 μg).
- Dosing: Most pills have a 21/7 regimen (21 active days and 7 placebo); alternatively, can take active pills continuously with four yearly scheduled withdrawal bleeds
- Initiation: recommended: quick start (begin pill on the day medication is obtained)
- Alternative: 1st day start (begin the pill on the 1st day of menses) or Sunday start (begin pill on first Sunday). If OCs are prescribed with Sunday or 1st-day-of-menses start, as many as 25% of women do not start.

- Weekly hormonal patch (Ortho Evra, Xulane):
  - Releases 20 μg/day ethinyl estradiol and 150 μg/day norelgestromin
  - Applied transdermally and changed weekly
  - Produces higher serum estrogen levels than oral 20-μg pill and may be associated with a slightly increased risk of blood clot
  - Patch may cause local skin irritation; reduced efficacy in women >90 kg

- Vaginal contraceptive ring (NuvaRing):
  - Flexible polymer ring with 15 μg/day of ethinyl estradiol and 120 μg/day of etonogestrel absorbed via vaginal wall
  - Insert into vagina for 3 weeks/cycle or use continuous cycling for 4 weeks, then replace immediately with a new ring (off-label).
  - Although systemic exposure to estrogen is about 50% of exposure with COCs, the risk of blood clots is about the same.

- Progestin-only birth control
  - Mechanism of action: thickening cervical mucus and thinning endometrial lining
  - Progestin-only pill (Micronor)
    - Efficacy: failure rate of about 0.3% with perfect use, 9% with typical use at 1 year (3)
    - Can be used in women with contraindication to estrogen, including breastfeeding women after 6 weeks postpartum
    - Dosing: 1 pill at the same time daily, no placebo days
    - Side effects: irregular bleeding
  - Injectable contraceptive (medroxyprogesterone acetate) “Depo-Provera”
    - Efficacy: failure rate of 0.2% with perfect use, 6% with typical use at 1 year (3)
    - Dosing: 150 mg IM or Depo-SubQ Provera 104 mg SC, both are given every 3 months.
    - Contraceptive levels of hormone persist for up to 4 months (2- to 4-week margin of safety).
    - Side effects include irregular bleeding, weight gain (average of 5 lb/year of use), and amenorrhea.

- LARCs: IUDs and implantable devices
  - Mirena (52-mg levonorgestrel-releasing IUD):
    - Mechanism of action: sterile inflammatory reaction due to foreign body that is toxic to sperm and ova, thickens cervical mucus, endometrial decidualization and glandular atrophy, inhibiting sperm-egg binding, partial inhibition of ovarian follicular development, and ovulation
    - Efficacy: failure rate of 0.2% with both perfect and typical use at 1 year (3)
- **Dosing**: releases 20 μg/day (very low serum levels) initially and subsequently reduces to 10 μg/day.
- **Approved for use up to 5 years; has been used off-label for up to 7 years**
- **Safe in nulliparous women/teenagers**
- **Can be inserted immediately postpartum or immediately following dilation and curettage for miscarriage or abortion; these are associated with higher rates of expulsion compared to delayed placement (6 to 10 weeks).**
- **Side effects**: irregular menstrual spotting for the first 3 to 6 months that usually resolves after 6 months of use; may see absence of menses after 1 year
- **Side effect management**: Consider NSAIDs, COCs, or progestin-only pills for spotting and cramps.
- **Can reduce heavy bleeding in menorrhagia**
  - **Liletta (52-mg levonorgestrel-releasing IUD)**:
    - Releases 18.6 μg/day initially; approved for 3 years, at which time it releases 12.6 μg/day
  - **Kyleena (19.5-mg levonorgestrel-releasing IUD)**:
    - Releases 17.5 μg/day for the 1st year, down to 7.5 μg/day. Approved for 5 years. Smaller insertion tube with 3.8 mm diameter offers potential for easier insertion in nulliparous women.
  - **Skyla (13.5-mg levonorgestrel-releasing IUD)**:
    - Releases 14 μg/day initially, down to 5 μg/day. Approved for 3 years. Smaller insertion tube (3.8 mm diameter); more bleeding days than Mirena
  - **ParaGard (copper IUD)**:
    - **Mechanism of action**: In addition to sterile inflammatory reaction due to foreign body, free copper and copper salts enhance the cytotoxic inflammatory reaction—toxic to sperm and ova.
    - **Efficacy**: failure rate of 0.6% with perfect use, 0.8% with typical use at 1 year (3)
    - **Approved for up to 10 years**
    - **Same insertion timing as levonorgestrel-IUD**
    - **Side effects**: increased menstrual bleeding and cramping
  - **Nexplanon (etonogestrel implant)**:
    - **Mechanism of action**: thickening cervical mucus and thinning endometrial lining
    - **Efficacy**: failure rate of 0.05% with perfect use, 0.3% with typical use at 1 year
    - **Dosing**: 40 mm × 2 mm semirigid plastic rod containing 68 mg of etonogestrel; initially releases 60 to 70 μg/day, down to 25 to 30 μg/day at the end of the 3rd year
    - **Effective for up to 3 years**
    - **Inserted only by certified providers**
    - **Side effects**: menstrual irregularities (common in first 6 to 12 months, may persist for 3 years)

- **Emergency contraception**: should be initiated as soon as possible post-unprotected intercourse. Copper IUD is the most effective, followed by ulipristal, levonorgestrel, and Yuzpe method (least effective) (5)[A].
  - **Copper-bearing IUD (ParaGard)**: Insert up to 5 days after intercourse; failure rate of 0.04–0.19%
  - **Ulipristal acetate (Ella)**: 30 mg once; selective progesterone modulator, effective up to 5 days after unprotected intercourse with minimal decline in efficacy; about 2% failure rate
  - **Levonorgestrel**: 1.5 mg taken as two 0.75-mg tablets (Plan B) or one 1.5-mg tablet (Plan B
One-Step). Failure rate: 1.1–2.4%. Less nausea than “Yuzpe regimen.” Available over the counter; may be less expensive if prescribed. Most effective within 72 hours, efficacy declines with time. Likely ineffective for women with BMI >30. Estradiol/levonorgestrel (Preven, Lo Ovral, Ogestrel): “Yuzpe regimen” 50 μg/0.25 mg, 2 tablets q12h (4 tablets total). Any OC may be used as long as the dose of estrogen component ≥100 μg/dose. Failure rate: 3.2%. Note: Antiemetic should be given 1 to 2 hours before each dose.

ADDITIONAL THERAPIES
- Male condoms: failure rate of 2% with perfect use, 18% with typical use at 1 year (3)
- Spermicides: All contain nonoxynol-9; may alter vaginal flora and mucosal barrier. Failure rate: 28% with typical use at 1 year (3)
- Sponge (Today Sponge): Soft foam disk contains nonoxynol-9. Moisten with water before use; effective for 24 hours; must leave in for 6 hours after use; less effective in parous women. Failure rate: 12–24% with typical use (3)
- Diaphragm: latex or silicone dome-shaped device with flexible spring-activated rim, works by preventing sperm from entering cervix; used with spermicides. Failure rate: 12% with typical use, 6% with perfect use at 1 year (3)

SURGERY/OTHER PROCEDURES
- Permanent sterilization
  - Female: tubal ligation. Failure rate: 0.5% at 1 year (3)
  - Male: vasectomy. Less complicated than female. Failure rate: 0.15% at 1 year (3)

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Fertility awareness methods: calendar method, cervical mucus method, temperature method. Low cost but generally not as effective as other methods. Failure rate: 24% at 1 year with typical use (3)
- Withdrawal method: Male withdraws from vagina before ejaculation. Failure if not timed accurately. Failure rate: 22% at 1 year with typical use (3)
- Lactational amenorrhea method: Breastfeeding is effective contraception only if the infant is <6 months old, the infant is exclusively breastfeeding, and the mother has not resumed regular menses. Failure rate: 7% at 1 year with typical use

Pediatric Considerations
- AAP and ACOG recommend LARCs as first-line agents for use in sexually active adolescents.
- Contraception counseling should include anticipated adverse effects, need to use condoms for STD prevention, and indications for emergency contraception (including options and how to obtain).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Pelvic exam, Pap smear, and STI testing per guidelines and routine follow-up 2 to 3 months postinitiation of all methods to assess tolerance
- Check for IUD strings 1 month after insertion; spontaneous expulsion rate highest in the 1st
month
- BP check within 3 months of initiation in patients on estrogen-containing methods

**DIET**
St. John’s wort may alter estrogen levels, reducing efficacy or causing breakthrough bleeding.

**PATIENT EDUCATION**
- Diaphragm: device inspected prior to each use, 1 tablespoon of spermicide in hollow of the dome, diaphragm is inserted into the vagina. If placed >6 hours prior to intercourse, need additional applicator of spermicide. Position must be checked postintercourse, and additional spermicide applied prior to each new episode of intercourse. Diaphragm should remain in place for at least 6 hours after the last episode of intercourse to maximize effectiveness.
- Male condoms: New condom is placed on the penis before genital contact, remains intact until the penis is withdrawn; new condom with every act of intercourse
- IUD: Patient should monitor presence of the string monthly following menses.
- OCP: Pill should be taken at the same time each day. Backup birth control method is needed for the first 7 days with quick start and Sunday start methods.

**COMPLICATIONS**
- Estrogen-progestin contraceptives:
  - Serious (requires discontinuation): stroke, thromboembolism, hypertension, myocardial infarction, and cholestatic jaundice
  - Overall 4-fold increased risk of VTE compared to nonusers, comparable to the 4-fold increased risk during pregnancy, but absolute risk is low (4)
- Injectable contraceptive:
  - Potential for decreased bone mineral density (BMD) if used for ≥2 years. Mostly recovers after discontinuation. Consider calcium/vitamin D supplementation if prolonged use.
- Nexplanon: insertion site reaction including pain, bleeding, paresthesias, and infection
- IUDs:
  - PID: Treat without removal unless serious infection or failure to respond to therapy.
  - Uterine perforation
  - Absolute risk of ectopic pregnancy is reduced with IUD, but if pregnancy does occur, there is a higher risk that it will be ectopic.
- Sponge and diaphragm: rarely associated with toxic shock syndrome

**REFERENCES**

ADDITIONAL READING

“CDC Contraception” Available as chart and app for smartphone

CODES

ICD10
- Z30.9 Encounter for contraceptive management, unspecified
- Z30.41 Encounter for surveillance of contraceptive pills
- Z30.431 Encounter for routine checking of intrauterine contracep dev

CLINICAL PEARLS

- Hormonal and IUD contraceptives may be initiated immediately if the likelihood of preexisting pregnancy is low.
- LARC methods provide high efficacy and convenience for patients.
- All patients should be counseled on emergency contraception options.
BASICS

DESCRIPTION

- The term “cor pulmonale” derives from the Latin cor (heart) and pulmonale (lungs). Hence, cor pulmonale is a cardiac complication of primary pulmonary disease.
- Acute or chronic pulmonary processes can lead to increased right-sided cardiac pressures. Resultant pulmonary hypertension (PH) subsequently induces structural alterations and/or impairs right ventricle (RV) function.
- PH is defined by a mean pulmonary artery pressure (mPAP) ≥25 mm Hg at rest measured by right heart catheterization.
- PH may be secondary to abnormalities of the pulmonary system, including disorders of the lung parenchyma, pulmonary circulation, chest wall, and/or ventilatory mechanisms. The pathophysiologic mechanisms of pulmonary arterial hypertension (WHO Group I) and PH secondary to pulmonary processes are biologically and clinically distinct. Therefore, for the purposes of this review, pulmonary arterial hypertension (WHO Group I) will not be considered as a cause of cor pulmonale.
- Cor pulmonale may occur in acute or chronic setting.
  - Acute: rapid increase of pulmonary arterial pressure resulting in RV overload, dysfunction, and potential cardiovascular collapse
  - Chronic: progressive hypertrophy and dilation of the RV over months to years, leading to dysfunction and potential failure

EPIDEMIOLOGY

- ~6–7% of all types of adult heart disease in United States. Globally, the incidence of cor pulmonale is widely variable due to air pollution, tobacco use, and toxic exposure.
- An estimated 10–30% of heart failure admissions in the United States are the result of cor pulmonale, most commonly related to chronic obstructive pulmonary disease (COPD).

Incidence
Difficult to assess: Best estimate is 1/10,000 to 3/10,000 per year.

Prevalence
Difficult to assess: Best estimate is 2/1,000 to 6/1,000.

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: A sudden event, such as large pulmonary embolism (PE), increases resistance to blood flow in the pulmonary vasculature, causing a quick and significant increase of pressure proximal to the right ventricular outflow tract. The RV may not be able to generate adequate force to overcome this pressure, leading to low RV cardiac output, which ultimately leads to a decreased left ventricle (LV) cardiac output. Increased RV pressures in conjunction with a low cardiac output may cause coronary ischemia, further impairing cardiac output and potentially causing complete cardiovascular collapse.
- Chronic: a disorder of the pulmonary system leading to chronic hypoxia, which results in
progressive vasoconstriction of the pulmonary vasculature. Over time, the pulmonary arterial system hypertrophies and intrinsic vasoactive mechanisms (mediated by nitric oxide, cyclooxygenase, and endothelin) become dysregulated, leading to an increase in pulmonary vasculature resistance.

- Increased pulmonary vascular resistance yields PH. PH transmits increased pressures and volumes to the thin-walled, low-pressure RV causing maladaptive remodeling (concentric hypertrophy, followed by eccentric dilation), which is frequently associated with tricuspid regurgitation and subsequent impairment in RV systolic and diastolic function.
- Indicators for the presence of PH in these patients may include a disproportionally low diffusing capacity of the lungs for carbon monoxide (DLCO) and an elevated pCO₂.

- Pulmonary disorders
  - Lung parenchymal disease: COPD (most common), interstitial lung disease (ILD), and pulmonary fibrosis
  - Pulmonary circulation: thromboembolic disease (associated with WHO Group IV PH)
  - Chest wall: severe obesity, kyphoscoliosis
  - Ventilation: obstructive sleep apnea (OSA) and obesity hypoventilatory syndrome; neuromuscular diseases such as Guillain-Barré syndrome, muscular dystrophy, myasthenia gravis, spinal cord injuries
- Left ventricular failure is not considered a cause of cor pulmonale.

RISK FACTORS
- Acute cor pulmonale (most commonly caused by PE)
- Chronic cor pulmonale (most commonly caused by underlying pulmonary disorder)
  - Risk factors associated with pulmonary disorders
    - Tobacco use (COPD)
    - Occupational exposures (ILD)
    - Hypercoagulable state (chronic thromboembolic disease)
    - Obesity, age (chest wall/ventilatory abnormalities)

GENERAL PREVENTION
Management of underlying pulmonary disorders, including aggressive correction of hypoxia and acidosis, which may contribute to worsening PH

COMMONLY ASSOCIATED CONDITIONS
PH, defined as the presence of a resting mPAP >25 mm Hg

DIAGNOSIS

HISTORY
- Dyspnea is the most common symptom. Although nonspecific, dyspnea may be present at rest, with exertion, or manifests as paroxysmal nocturnal dyspnea.
- Other pulmonary symptoms: pleuritic chest pain, cough, hemoptysis
- General heart failure symptoms: fatigue, lethargy, syncope; exertional angina less likely
- Right-sided heart failure symptoms: anorexia, early satiety, digital cyanosis, clubbing, right upper quadrant discomfort (hepatic congestion), lower extremity edema
- Hoarseness secondary to compression of the left recurrent laryngeal nerve by enlarged
pulmonary vessels
- Cardiovascular collapse, shock, and/or cardiac arrest may occur in acute or advanced chronic setting.

**PHYSICAL EXAM**
- Peripheral edema is the most common sign of right-sided heart failure, although it is nonspecific.
- General: pallor, diaphoresis, clubbing, cyanosis, tachypnea
- Neck: jugular venous distention, with prominent a-wave
- Lungs: tachypnea, wheezing
- Heart
  - Increased intensity of pulmonic component of second heart sound (P$_2$)
  - Splitting of S$_2$ over the cardiac apex with inspiration
  - Audible right-sided S$_3$ or S$_4$
  - RV heave
  - Pansystolic murmur heard best at right midsternal border increasing with inspiration, consistent with tricuspid regurgitation (typically a late sign)
- Abdomen: hepatomegaly
- Extremities: clubbing, cyanosis, bilateral lower extremity edema, may also signs of deep vein thrombosis (DVT) such as tenderness or unilateral swelling

**DIFFERENTIAL DIAGNOSIS**
Other causes of right-sided failure:
- Left-sided heart failure
- WHO Groups I, II, and V PH
- Right-sided intrinsic cardiomyopathy

**DIAGNOSTIC TESTS & INTERPRETATION**
- 2D echocardiogram (1)[C]
  - Initial diagnostic test of choice
  - Elevated pulmonary arterial pressures
  - Right ventricular hypertrophy
  - Bulging of the interventricular septum into the LV with systole
  - Flattening of the interventricular or interatrial septum
  - Dilation and hypokinesis of the RV
  - Tricuspid regurgitation
  - Dilation of the right atrium
  - Acute thromboembolic pulmonary disease as evidenced by right ventricular hypokinesis with sparing of the apex (McConnell sign)
  - Echocardiography can over- or underestimate the pulmonary arterial pressures depending on image quality or operator. Pulmonary arterial pressures should therefore be verified by right heart catheterization.
- MRI
  - If echocardiography is inconclusive or as a substitute
  - Most accurate modality for diagnosing emphysema and ILD
  - Can assess cardiac pressures, size, function, myocardial mass, and viability
- Right heart catheterization (1)[C]
- Gold standard for diagnosis of PH and therefore critical for diagnosis of cor pulmonale
- Elevated central venous pressure (CVP)
- Mean PAP ≥25 mm Hg at rest

**Initial Tests (lab, imaging)**
- CBC may show signs of polycythemia due to chronic hypoxia.
- Basic metabolic panel (BMP) may demonstrate elevated creatinine secondary to poor cardiac output.
- Liver function tests (LFTs) may be abnormal due to proximal hepatic congestion or poor distal cardiac output secondary to RV failure.
- Brain natriuretic peptide (BNP) and cardiac troponin can be elevated secondary to right ventricular strain.
- D-dimer may be positive as evidence of underlying thromboembolic pulmonary disease.
- Arterial blood gas may show hypercapnia due to COPD or hypoxemia due to ILD.
- Arterial blood gases of COPD patients show a decreased PaO₂ with normal or increased PaCO₂.
- ECG often shows signs of right-sided enlargement.
  - Right axis deviation
  - An R/S wave ratio >1 in V₁
  - Right ventricular hypertrophy (R wave in V₁ and V₂ with S waves in V₅ and V₆)
  - Right atrial enlargement as evidenced by P pulmonale (increased amplitude of P wave in leads II, III, and avF with a “tent-like” appearance)
  - Incomplete or complete right bundle branch block
  - S₁S₂S₃ pattern or S₁Q₃T₃ inverted pattern
- Chest x-ray
  - Cardiomegaly
  - Enlargement of the central pulmonary arteries and reduced size of peripheral vessels (oligemia)
  - Reduced retrosternal space due to right ventricular enlargement on lateral views
  - Enlargement of the right atrium resulting in prominence of the right heart border
  - Evidence of COPD, ILD, and structural disease (i.e., kyphosis)
  - Evidence of PE (Westermark sign, Fleischner sign, and Hampton hump)
- Spiral computed tomography (CT) scan of chest
  - Diagnosis of acute PE
  - Diagnosis of COPD and ILD
- Ventilation/perfusion (V/Q) scan
  - High specificity and sensitivity for acute and chronic thromboembolic disease
  - Screening method of choice for chronic thromboembolic PH because of its higher sensitivity compared with CT pulmonary angiogram
  - May be used for diagnosis of acute thromboembolic disease if contraindication to chest spiral CT
  - Diagnosis of chronic thromboembolic disease (WHO Group IV PH) may warrant confirmation by pulmonary angiography.
- Pulmonary angiography
  - Gold standard in diagnosis of chronic thromboembolic pulmonary disease
- Polysomnography
– Gold standard for diagnosis of OSA

• Pulmonary function tests (PFTs)
  – DLCO: A decrease in lung volume combined with decreased diffusion capacity for carbon monoxide may indicate ILD. COPD is associated with a decreased DLCO.
  – Obstructive or restrictive ventilatory defects (ILD, chest wall abnormalities, and COPD)

**TREATMENT**

Reduce symptoms, improve quality of life, and increase survival. Reduce disease burden via oxygenation, preservation of cardiac function, and attenuation of PH.

**GENERAL MEASURES**

• Treat underlying disease (2)[A].
  – For underlying pulmonary disease, long-acting bronchodilators, long-acting antimuscarinic agents, and/or inhaled corticosteroids may be beneficial for long-term disease management.
  – For underlying chronic thromboembolic disease, anticoagulation may be indicated.

• Supportive therapy as necessary
  – Continuous positive airway pressure/bilevel positive airway pressure may be used for hypoxia/sleep disorders.
  – Ventilation using positive-pressure masks, negative-pressure body suits, or mechanical ventilation is suggested for patients with neuromuscular disease.
  – Phlebotomy may be indicated for severe polycythemia or signs and symptoms of hyperviscosity (hematocrit >55%).

**MEDICATION**

• Oxygen (3)[A]
  – Long-term continuous oxygen therapy improves the survival of hypoxemic patients with COPD and cor pulmonale.
  – All patients with PH whose PaO₂ is consistently <55 mm Hg or saturation ≤88% at rest, during sleep, or with ambulation should be prescribed oxygen to keep O₂ >92 mm Hg.
  – Exposure to high altitude should be avoided. Supplemental oxygen should be used during altitude exposure or air travel as needed to maintain oxygen saturations >91%.

• Preservation of cardiac function (4)[B]
  – Inotropes: Dobutamine and milrinone may improve cardiac output.
  – Diuretics: decrease RV filling pressures and reduce peripheral edema secondary to RHF
    o Excessive volume depletion should be avoided.
    o Monitor closely for metabolic alkalosis because this may suppress ventilatory drive and contribute to hypoxia.

• Ameliorate PH (1, 4)[C].
  – Treatment of underlying disease is hallmark of management.
  – When refractory to traditional medical treatment, advanced therapies may be beneficial, although evidence is lacking.
  – For chronic thromboembolic–associated PH (WHO Group IV), riociguat and macitentan may be used.

**ISSUES FOR REFERRAL**
Patients with cor pulmonale should be referred to a specialized center for expert consultation.

**SURGERY/OTHER PROCEDURES**

- Endarterectomy for chronic thromboembolic disease (WHO Group IV)
- Lung volume reduction surgery (LVRS) is a surgical option that may be beneficial for patients with advanced upper-lobe predominant emphysema who have poor disease control despite maximal medical therapy (5).
- Moderate to severe disease refractory to medication may require lung and/or heart transplantation.

**ONGOING CARE**

**DIET**
Salt and fluid restriction

**PATIENT EDUCATION**
- Smoking cessation and avoidance of exposure to secondary smoke is strongly recommended.
- Level of physical activity should be discussed with physician.
- Pregnancy should be avoided.

**PROGNOSIS**
Patients with cor pulmonale resulting from COPD have a greater likelihood of dying than do similar patients with COPD alone. In patients with COPD and mild disease (PAP 20 to 35 mm Hg), 5-year survival is 50%.

Pulmonary Embolism
  ● Algorithm: Congestive Heart Failure: Differential Diagnosis

CODES

ICD10
  ● I27.81 Cor pulmonale (chronic)
  ● I26.09 Other pulmonary embolism with acute cor pulmonale

CLINICAL PEARLS
  ● Treatment of cor pulmonale requires treatment of the underlying disease. Therefore, accurate diagnosis of primary pulmonary disease is critical to clinical management and treatment therapy.
  ● Continuous, long-term oxygen therapy improves life expectancy and quality of life in cor pulmonale.
  ● Referral of patients with cor pulmonale to a specialized center is strongly recommended.
CORNEAL ABRASION AND ULCERATION
Sophia Margareth Marie Tribié, MD ● Christine S. Persaud, MD, CAQSM

BASICS

DESCRIPTION
- Corneal abrasions: result from cutting, scratching, or abrading the thin, protective, clear coat of the exposed anterior portion of the ocular epithelium. These injuries cause pain, tearing, photophobia, foreign body sensation, and a gritty feeling (1).
- Corneal ulceration: break in the epithelial layer of the cornea leading to exposure of the underlying corneal stroma, which results in a corneal ulcer. Superficial ulcers, limited to loss of the corneal epithelium, are the most common form of ulceration (2).
- Corneal abrasion and ulceration can both lead to impaired vision from scarring.

EPIDEMIOLOGY

Incidence
- Corneal abrasions are commonly seen in primary care. Eye-related diagnoses make up 8% of total ER visits. Of those eye-related visits, 45% are corneal abrasions. Abrasions are the third leading cause of red eye, following conjunctivitis and subconjunctival hemorrhage (3).
- Associated with significant morbidity and loss of productivity

ETIOLOGY AND PATHOPHYSIOLOGY
- Corneal abrasions are most often caused by mechanical trauma but may also result from foreign bodies: sand and dust, contact lenses wear, or chemical and flash burns.
- Corneal ulceration: Contact lenses use, HIV, trauma, ocular surface disease, and ocular surgery increase the incidence. Edema plays a major role in epithelial defect. Edema can lead to trauma, ischemia, and increased intraocular pressure. Excessive fluid disrupts the normal architecture of the epithelial layer (4).
- Causes of ulcerations include the following:
  - Infection with gram-positive organisms ~29–53% (Staphylococcus aureus and coagulase-negative Streptococcus are common ones.)
  - Infection with gram-negative organisms ~47–50% (Pseudomonas being most common, followed by Serratia marcescens, Proteus mirabilis, and gram-negative enteric bacilli)
  - Herpes simplex with bacterial superinfection
  - Varicella virus
  - Corneal abrasion and eye surgery (cataract, eye transplant)
  - Autoimmune disorder: Sjögren, rheumatoid arthritis, inflammatory bowel disease
- Increased risk of corneal ulceration in HIV and diabetes mellitus (DM) patients and immunocompromised such as cancer
- Eyelid abnormalities (chronic blepharitis, entropion)
- Nutritional deficiencies (vitamin A and protein undernutrition)
- Dry eyes/bullous keratopathy/mucous membrane pemphigoid

RISK FACTORS
- History of trauma (direct blunt trauma, chemical burn, radiation exposure, etc.)
- Contact lenses wear
- Male gender
- Age: 20 to 34 years old
- Job (construction, manufacturing)
- Lack of eye protection

**GENERAL PREVENTION**
Protective eyewear during work (auto mechanics, metal workers, miners, etc.) and during sports

**COMMONLY ASSOCIATED CONDITIONS**
- Vitamin A deficiency is associated with corneal ulcers.
- Neuropathy of cranial nerve (CN) V
- DM, thyroid dysfunction, immunocompromised states, connective tissue disease

---

**DIAGNOSIS**

**HISTORY**
Corneal abrasion is a clinical diagnosis. It includes a history of recent ocular trauma and acute pain. Other symptoms include photophobia, pain with extraocular muscle movement, eye twitching, excessive tearing, blepharospasm, foreign body sensation, gritty feeling, blurred or decreased vision, nausea, and headache.

**PHYSICAL EXAM**
- Gross examination of the anatomy: eyelids, surface of the eye, pupils, and extraocular muscles
- Snellen chart
- Tonometry
- Penlight
- Blepharospasm: fluorescein stain
- Wood lamp (5)

**DIFFERENTIAL DIAGNOSIS**
- Corneal abrasion
  - Acute angle-closure glaucoma
    - Conjunctivitis
  - Infective keratitis
    - Uveitis
    - Keratoconjunctivitis (3,5)
- Corneal ulceration
  - Herpes zoster
    - Herpes zoster ophthalmicus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Ulcer culture
- Pretreatment with topical antibiotics may alter culture results.
Diagnostic Procedures/Other
- Slit lamp and fluorescein dye to identify and evaluate corneal abrasions
- Trauma/foreign body has geographic shape; if due to contact lenses, several punctate lesions (5)
- Document visual acuity.

Test Interpretation
Scraping culture/staining identifies bacteria, yeast, or intranuclear inclusions to help narrow diagnosis.

TREATMENT

GENERAL MEASURES
- Most uncomplicated corneal abrasions heal in 24 to 48 hours.
- May not require follow-up if lesion is <4 mm, uncomplicated abrasion, normal vision, and resolving symptoms
- But untreated abrasions can lead to corneal ulceration
- Do not rinse with tap or bottled water because it may contain microorganisms such as Acanthamoeba; instead rinse with a saline solution or multipurpose contact lens solutions.
- Patching not recommended
  - Does not reduce pain
  - Delays healing (4)[A]

MEDICATION
- Treatment guidelines: pain control, infection prevention, and daily symptom monitoring
- Oral analgesic: narcotics, acetaminophen, nonsteroidal anti-inflammatory drugs (NSAIDs)
- Topical anesthetics include proparacaine hydrochloride 0.1–0.5%, tetracaine hydrochloride 1%.
  - Proparacaine may be less cytotoxic than tetracaine (4)[B].
  - Topical anesthetics should be avoided after initial examination because they can retard healing and cause corneal damage.

First Line
- Ophthalmic NSAIDs: Diclofenac 0.1% one drop QID helps relieve moderate pain:
  - Alternatives include ketorolac 0.5% one drop QID and bromfenac 0.09%.
  - Caution: Ophthalmic NSAIDs may rarely cause corneal melting and perforation.
  - Caution in patients with bleeding tendency
- Ophthalmic antibiotics may help prevent further infection and ulceration of corneal abrasions (6)[C].
  - Some ophthalmic antibiotics include bacitracin 500 IU BID or QID, ofloxacin/ciprofloxacin 0.3%, gentamicin 0.3%, erythromycin 0.5%, polymyxin B/trimethoprim (Polytrim), and tobramycin 0.3%.
  - Antipseudomonas antibiotics should be used, especially if patient wears contact lenses; wearing contacts should be discontinued until healing and completion of treatment.
- Large corneal abrasions (>4 mm) or very painful abrasions should be treated with a combination of topical antibiotic and topical NSAID.
Fungal keratitis is treated with a protracted course of topical antifungal agents (by ophthalmologist).
Herpetic keratitis should be referred promptly to ophthalmologist and treated initially with trifluridine:
  – Vidarabine and acyclovir are alternatives.

ISSUES FOR REFERRAL
Indications for referral include:
  – Chemical burn
  – Evidence of corneal ulcer or infiltrate
  – Failure to heal after 3 to 4 days
  – Inability to remove a foreign body
  – Increase size of abrasion after 24 hours
  – Penetrating injury
  – Presence of hyphema (blood) or hypopyon (pus)
  – Rust ring
  – Vision loss of >20/40

Worsening symptoms or improvement after 24 hours (5)
  – Immediate ophthalmology consultation for corneal ulceration for culture and initiation of treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
  – Most uncomplicated corneal abrasions heal in 24 to 48 hours.
  – Follow-up not necessary for small (<4 mm), uncomplicated abrasions, normal vision, and resolving symptoms
  – Lesions >4 mm, decreased vision, and abrasions due to contact lenses need follow-up within 24 hours (3)[C].

PATIENT EDUCATION
Prevention of abrasions and proper handling of contact lenses can prevent recurrence of corneal ulcers.

PROGNOSIS
  – Corneal abrasions heal within 24 to 72 hours.
  – Ophthalmology consult with penetrating eye injury

COMPLICATIONS
  – Recurrence
  – Scarring of the cornea
  – Loss of vision

REFERENCES

**CODES**

**ICD10**
- S05.00XA Inj conjunctiva and corneal abrasion w/o fb, unsp eye, init
- H16.009 Unspecified corneal ulcer, unspecified eye
- H16.049 Marginal corneal ulcer, unspecified eye

**CLINICAL PEARLS**
- Contact lenses use should be discontinued until corneal abrasion or ulcer is healed and pain is fully resolved.
- Eye patching is not recommended.
- Prescribe topical and/or oral analgesic medication for symptom relief, and consider ophthalmic antibiotics.
- Healing can take 2 to 3 days for small abrasion (4 mm); for larger one, may take 4 to 5 days.
- Treatment usually involves frequent topical antimicrobials application (e.g., every 1 to 2 hours).
- Prompt referral to an ophthalmologist should be made with suspicion of an ulcer, recurrence of abrasion, retained foreign body, viral keratitis, significant visual loss, or lack of improvement despite therapy.
CORNS AND CALLUSES
Sangili Chandran, MD, MS(ortho) ● Valerie Rygiel, DO

BASICS

DESCRIPTION

- A callus (tyloma) is a diffuse area of hyperkeratosis, usually without a distinct border.
  - Typically, the result of exposure to repetitive forces, including friction and mechanical pressure; tend to occur on the palms of hands and soles of feet (1)
- A corn (heloma) is a circumscribed hyperkeratotic lesion with a central conical core of keratin that causes pain and inflammation. The conical core in a corn is a thickening of the stratum corneum.
- Hard corn or heloma durum (more common): often on toe surfaces, especially 5th toe (proximal interphalangeal [PIP]) joint
- Soft corn or heloma molle: commonly in the interdigital space (1)
- Digital corns are also known as clavi or heloma durum.
- Intractable plantar keratosis is usually located under a metatarsal head (1st and 5th most common), is typically more difficult to resolve, and often is resistant to usual conservative treatments.

EPIDEMIOLOGY

Corns and calluses have the largest prevalence of all foot disorders.

Incidence

- Incidence of corns and calluses increases with age.
- Less common in pediatric patients
- Women affected more often than men
- Blacks report corns and calluses 30% more often than whites.

Prevalence

- 9.2 million Americans
- ~38/1,000 people affected

ETIOLOGY AND PATHOPHYSIOLOGY

Increased activity of keratinocytes in superficial layer of skin leads to hyperkeratosis. This is a normal response to excess friction, pressure, or stress.

- Calluses typically arise from repetitive friction, motion, or pressure to skin. The increased pressure is often secondary to a metatarsal deformity (long metatarsal or plantarflexed metatarsal) or another bone spur or deformity.
- Hard corns are an extreme form of callus with a keratin-based core. Often found on the digital surfaces and commonly linked to bony protrusions, causing skin to rub against shoe surfaces.
- Soft corns arise from increased moisture from perspiration leading to skin maceration, along with mechanical irritation, especially between toes.

Genetics

No true genetic basis was identified because most corns and calluses are due to mechanical
stressors on the foot/hands.

**RISK FACTORS**
- Extrinsic factors producing pressure, friction, and local stress
  - Ill-fitting shoes or walking barefoot
  - Not using socks/gloves
  - Activities that increase stress applied to skin of hands or feet (manual labor, running, walking, sports)
- Intrinsic factors
  - Bony prominences: bunions, hammertoes, mallet deformities, deformed metatarsals
  - Motor or sensory neuropathy such as secondary to diabetes

**GENERAL PREVENTION**
External irritation and pressure are by far the most common cause of calluses and corns. General measures to reduce friction or pressure on the skin are recommended to reduce incidence of callus formation. Examples include wearing shoes that fit well and using socks and gloves.

**Geriatric Considerations**
In elderly patients, especially those with neurologic or vascular compromise, skin breakdown from calluses/corns may lead to increased risk of infection/ulceration. 30% of foot ulcers in the elderly arise from eroded hyperkeratosis. Regular foot exams are emphasized for these patients as well as diabetic patients (2).

**COMMONLY ASSOCIATED CONDITIONS**
- Foot ulcers: especially noted in diabetic patients or patients with neuropathy or vascular compromise
- Infection: look for warning signs including
  - Increasing size, redness, pain, or swelling
  - Purulent drainage
  - Fever
  - Change in color of fingers or toes
- Signs of gangrene (color change, coolness)

**DIAGNOSIS**
- Most commonly a clinical diagnosis based on visualization of the lesion
- Examination of footwear may also provide clues.

**HISTORY**
- Careful history can usually pinpoint cause.
- Ask about neurologic and vascular history and diabetes. These may be risk factors for progression of corns/calluses to frank ulcerations and infection.

**PHYSICAL EXAM**
- Calluses
  - Thickening of skin without distinct borders
  - Often on feet, hands; especially over palms of hands, soles of feet
  - Colors range from white to gray-yellow, brown, red
– May be painless or tender
– May throb or burn

* Corns
  – Hard corns
    – Commonly on feet: dorsum of toes or 5th PIP joint
    – Varied texture: dry, waxy, and transparent to a hornlike mass
    – Distinct borders
    – Often painful
  – Soft corns
    – Commonly between toes, especially between 4th and 5th digits at the base of the web space
    – Often yellowed, macerated appearance
    – Often extremely painful

**DIFFERENTIAL DIAGNOSIS**
* Plantar warts (typically a loss of skin lines within the wart), which are viral in nature
* Porokeratoses (blocked sweat gland)
* Underlying ulceration of skin, with or without infection (important to rule out especially with diabetic patients)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
  – Radiographs may be warranted if no external cause is found. Look for abnormalities in foot structure, bone spurs.
  – Use of metallic radiographic marker and weight-bearing films often highlight the relationship between the callus and bony prominence.

**Diagnostic Procedures/Other**
Biopsy with microscopic evaluation in rare cases

**Test Interpretation**
Abnormal accumulation of keratin in epidermis, stratum corneum

---

**TREATMENT**

**GENERAL MEASURES**
* Most therapy for corns and calluses can be done as self-care in the home (1).
* Use bandages, soft foam padding, or silicone sleeve over the affected area to decrease friction on the skin and promote healing with digital clavi.
* Use socks or gloves regularly.
* Padding to offload bony prominences
* Low-heeled shoes; soft upper with deep and wide toe box
* Avoidance of activities that contribute to painful lesions
* Prefabricated or custom orthotics

**MEDICATION**
* Keratolytic agents, such as urea or ammonium lactate, can be applied safely.
• Intralesional bleomycin injections have shown improvement in size and pain of warts.
• In office débridement of affected tissue and use of protective padding
• Use sandpaper discs or pumice stones over hard, thickened areas of skin; can be done safely at home

Geriatric Considerations
Use of salicylic acid on corn plasters can cause skin breakdown and ulceration in patients with thin, atrophic skin; diabetes; and those with vascular compromise. The skin surrounding the callus will often turn white and can become quite painful. Sometimes the acids are weak enough to not penetrate the thick skin but they can burn the adjacent skin, making the condition worse. Aggressive use of pumice stones can also lead to skin breakdown, especially surrounding the callus.

ISSUES FOR REFERRAL
• May benefit from referral to podiatrist if use of topical agents and shoe changes are ineffective
• Abnormalities in foot structure may require surgical treatment.
• Diabetic, vascular, and neuropathic patients may benefit from referral to podiatrist for regular foot exams to prevent infection or ulceration.

SURGERY/OTHER PROCEDURES
• Surgical treatment to areas of protruding bone where corns and calluses form
• Rebalancing of foot pressure through functional foot orthotics
• Shaving or cutting off hardened area of skin using a chisel or 15-blade scalpel. For corns, remove keratin core and place pad over area during healing.

COMPLEMENTARY & ALTERNATIVE MEDICINE
• May benefit from urea-based lotions, creams, or ointments
• Warm water/Epsom salt soaks

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Admission usually not necessary, unless progression to ulcerated lesion with signs of severe infection, gangrene
• May require aggressive débridement in operating room if an abscess or deep-space infection is suspected. Deep-space infections can develop where an abscess can penetrate into tendon sheaths and/or deep compartments within the foot or hand, potentially leading to rapid sepsis. Vascular status must be assessed and vascular referral considered.
• Nursing
  – Wound care, dressing changes for infected lesions

ONGOING CARE

PATIENT EDUCATION
• General information: https://www.mayoclinic.org/diseases-conditions/corns-and-calluses/basics/definition/con-20014462
• American Podiatric Medical Association: http://www.apma.org

PROGNOSIS
Complete cure is possible once factors causing pressure or injury are eliminated.

**COMPLICATIONS**
Ulceration, infection

**REFERENCES**

**ADDITIONAL READING**
- American College of Foot and Ankle Surgeons: [http://www.acfas.org/](http://www.acfas.org/)

**CODES**

**ICD10**
L84 Corns and callosities

**CLINICAL PEARLS**
Most therapy for corns and calluses can be done as self-care in the home using padding over the affected area to decrease friction or pressure. However, if simple home care is not helpful, then removal of the lesions is often immediately curative.
BASICS

DESCRIPTION

- Coronary artery disease (CAD) refers to the atherosclerotic narrowing of the epicardial coronary arteries. It may manifest insidiously as angina pectoris or as an acute coronary syndrome (ACS).
- Stable angina is a chest discomfort due to myocardial ischemia that is predictably reproducible at a certain level of exertion or emotional stress.
- The spectrum of ACS includes unstable angina (UA), non–ST elevation myocardial infarction (NSTEMI), and ST elevation myocardial infarction (STEMI). See chapters on ACS for further information.
- Definitions
  - Typical angina: exhibits three classical characteristics: (i) substernal chest pressure, pressure, or heaviness that may radiate to the jaw, back, or arms and generally lasts from 2 to 15 minutes; (ii) occurs at a certain level of myocardial oxygen demand from exertion, emotional stress, or increased sympathetic tone; and (iii) relieved with rest or sublingual nitroglycerin
  - Atypical angina: exhibits two of the above typical characteristics
  - Noncardiac chest pain: exhibits ≤1 of the above typical characteristics
  - Anginal equivalent: Patients may present without chest discomfort but with nonspecific symptoms such as dyspnea, diaphoresis, fatigue, belching, nausea, light-headedness, or indigestion that occur with exertion or stress. Patients with diabetes mellitus, women, and the elderly may present with more atypical features as compared to the general population.
  - UA: anginal symptoms that are new or more frequent, more severe, or occurring with lessening degrees of myocardial demand; it is considered ACS but does not present with cardiac biomarker elevation. (See “Acute Coronary Syndromes: NSTE-ACS (Unstable Angina and NSTEMI)” chapter.)
  - NSTEMI: elevation of cardiac biomarker (troponin) with either anginal symptoms, ischemic ECG changes other than ST elevation, or both. (See “Acute Coronary Syndromes: NSTE-ACS (Unstable Angina and NSTEMI)” chapter.)
  - STEMI: presents with typical symptoms as mentioned above with ST elevations noted on ECG; generally caused by acute plaque rupture and complete obstruction of culprit vessel and may present prior to laboratory detection of troponin. (See “Acute Coronary Syndromes: STEMI” chapter.)
- Canadian Cardiovascular Society grading scale:
  - Class I: Angina does not limit ordinary physical activity, occurring only with strenuous or prolonged exertion (7 to 8 metabolic equivalents [METs]).
  - Class II: Angina causes slight limitation of ordinary activity. It occurs when walking rapidly, uphill, or >2 blocks; climbing >1 flight of stairs; or with emotional stress (5 to 6 METs).
– Class III: Angina causes marked limitation of ordinary physical activity. It occurs when walking 1 to 2 blocks or climbing one flight of stairs (3 to 4 METs).
– Class IV: Angina occurs with any physical activity and may occur at rest (1 to 2 METs).

**Geriatric Considerations**
- The elderly may present with atypical symptoms.
- Physical limitations may delay recognition of angina until it occurs with minimal exertion or at rest.
- Maintain a high degree of suspicion during evaluation of dyspnea and other nonspecific complaints.
- Geriatric patients may be very sensitive to the side effects of medications used to treat angina.

**Epidemiology**
- CAD is the leading cause of death for adults both in the United States and worldwide.
- CAD is responsible for about 1 in every 3 deaths in the United States alone.
- The cost of CAD in the United States was $555 billion in 2016 and is expected to rise to $1.1 trillion by 2035.
- ~80% of CAD is preventable with a healthy lifestyle.

**Incidence**
In the United States, the lifetime risk of a 40 year old developing CAD is 49% for men and 32% for women.

**Prevalence**
In the United States, 28.4 million people carry a diagnosis of CAD, whereas 7.12 million have angina pectoris.

**Etiology and Pathophysiology**
- Anginal symptoms occur during times of myocardial ischemia caused by a mismatch between coronary perfusion and myocardial oxygen demand.
- Atherosclerotic narrowing of the coronary arteries is the most common etiology of angina, but it may also occur in those with significant aortic stenosis, pulmonary hypertension, hypertrophic cardiomyopathy, coronary spasm, or volume overload.
- Sensory nerves from the heart enter the spinal cord at levels C7–T4, causing diffuse referred pain/discomfort in the associated dermatomes.

**Risk Factors**
- Traditional risk factors: hypertension, ↓ high-density lipoprotein, ↑ low-density lipoprotein (LDL), smoking, diabetes, premature CAD in first-degree relatives (men <55 years old; women <65 years old), age (>45 years for men; >55 years for women)
- Nontraditional risk factors: obesity, sedentary lifestyle, chronic inflammation, abnormal ankle-brachial indices, renal disease

**General Prevention**
- Smoking cessation
- Regular aerobic exercise program
- Weight loss for obese patients (goal body mass index (BMI) <25 kg/m²)
- Blood pressure (BP) control (goal <140/90 mm Hg; consider <130/80 mm Hg for those with 10-year ASCVD risk ≥10%) (1)[C]
Diabetes management

Statin therapy for those with diabetes age 40 to 75 years and those with 10-year ASCVD risk $\geq 7.5–10\%$ (recommendations of advisory organizations vary, and the American College of Cardiology/American Heart Association risk calculator overestimates risk in many)

Low-dose aspirin should no longer be recommended for routine primary prevention of myocardial infarction (MI) without objective evidence of CAD. Benefits and harms are closely balanced, with no strong evidence for reduction in all-cause mortality, but with evidence for a reduction in cardiovascular events at the cost of increased major GI bleeding (2)[A]. A shared decision-making approach may consider aspirin for primary prevention in patients aged 50–69 at highest risk of coronary artery disease and at low risk of GI bleeding (2)[A]. It may be used for those with high clinical suspicion in the interim prior to stress testing/catheterization.

COMMONLY ASSOCIATED CONDITIONS
Hyperlipidemia, peripheral vascular disease, cerebrovascular disease, hypertension, obesity, diabetes

DIAGNOSIS

HISTORY

- Careful history is important to elicit symptoms.
- Pain may be described with a clenched fist over the center of the chest (Levine sign).
- Discomfort is usually not affected by position or deep inspiration.
- Episodes of angina are generally of the same character and in the same location as previous episodes.
- Recent decrease in level of physical activity may be due to worsening anginal symptoms.
- Dyspnea on exertion may present as the only symptom. Atypical symptoms are more likely in women, the elderly, and diabetic patients.
- May present with symptoms similar to gastric reflux or GI upset (indigestion, nausea, diaphoresis)

PHYSICAL EXAM

- Normal cardiac exam does not exclude the diagnosis of angina or CAD.
- Cardiac exam may reveal dysrhythmias, heart murmurs indicative of valvular disease, gallops, or signs of congestive heart failure.
- Evidence of peripheral vascular disease (diminished pulses, bruits, abdominal aortic aneurysm [AAA]) may or may not be noted.

DIFFERENTIAL DIAGNOSIS

- Vascular: aortic dissection, pericarditis, myocarditis, MI, vasospasm
- Pulmonary: pleuritis, pulmonary embolism, pneumothorax
- Gastroesophageal: gastric reflux, esophageal spasm, peptic ulcer
- Musculoskeletal: costochondritis, arthritis, muscle strain, rib fracture
- Other: anxiety, psychosomatic, cocaine abuse

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Serial cardiac troponins for those presenting acutely with symptoms
Complete blood count, lipid profile, HgbA1c for risk stratification
Basic metabolic panel to rule out electrolyte abnormalities and assess renal function
ECG
  – Should be obtained unless there is a noncardiac cause of the chest pain
  – Frequently unremarkable between anginal episodes; may show signs of myocardial ischemia during symptomatic episodes, evidence of old MI
  – Left bundle branch block or ventricular pacing makes interpretation for ischemia unreliable.
Chest x-ray may exclude other causes of pain.

Follow-Up Tests & Special Considerations
Goal is to detect high-risk coronary lesions where intervention would improve long-term mortality or alleviate anginal symptoms.
Stress testing is most helpful for patients at intermediate risk of CAD.
  – Exercise testing for those who can physically exercise (≥5 METs)
    o Standard exercise ECG for those with normal baseline ECG (i.e., without left bundle branch block or ventricular pacing)
    o Exercise stress testing with echo or perfusion imaging for those with abnormal baseline ECG or in premenopausal women
  – In patients who cannot tolerate exercise, consider pharmacologic stress testing.
Echocardiogram should be obtained in patients with a new or loud (≥III/VI) murmur, evidence of MI, symptoms of heart failure, concern for hypertrophic cardiomyopathy or pericardial effusion, and in those with new arrhythmias. A normal echocardiogram does not rule out CAD.
Echocardiogram can be considered in patients with hypertension or diabetes and abnormal ECG.
CT coronary angiography or cardiac MRI can be considered as a supplement/alternative to stress testing in patients with continued symptoms despite negative stress testing, inconclusive stress testing, or need for better anatomic definition of disease.

Diagnostic Procedures/Other
Cardiac catheterization with coronary angiography is the gold standard for confirmation and delineation of coronary disease and direction of interventional therapy or surgery. It is indicated if noninvasive testing suggests a high-risk lesion or if patient fails to respond to appropriate medical management.
Significant CAD is defined as ≥50% stenosis of the left main coronary artery or ≥70% stenosis of other major coronary arteries by angiography.
Borderline lesions may be assessed with a pressure wire. Fractional flow reserve (FFR) of ≤0.8 demonstrates a hemodynamically significant lesion.

TREATMENT
GENERAL MEASURES
BP control goal for most patients with significant CAD: <130/80 mm Hg (1)[A].
Smoking cessation goal: complete cessation, no exposure to secondhand smoke or e-cigarettes
Physical activity goal: 30 to 60 minutes of moderate aerobic activity, at least 5 (preferably 7) days/week
Weight management goal: BMI 18.5 to 24.9 kg/m²; waist circumference <35 inches (women) or <40 inches (men)

Individualize glycemic control goals in diabetics: Avoid hypoglycemic episodes.

**MEDICATION**

**First Line**

- **β-Blockers:** decrease myocardial oxygen demand by lowering heart rate, BP, and contractility
  - Improve mortality in patients with MI or heart failure and should be used as initial therapy
  - Can improve symptoms of angina
  - Metoprolol (25 to 400 mg daily [succinate] or divided BID [tartrate]) or carvedilol (3.125 to 25 mg BID). Adjust doses according to clinical response. Maintain resting heart rate 50 to 60 bpm.
  - Side effects: bradycardia, fatigue, and sexual dysfunction predominantly in men

- **Calcium channel blockers (CCBs):** cause arterial vasodilation, decreased myocardial oxygen demand, and improved coronary blood flow. Similar effectiveness to β-blockers; may be used instead of or in addition to β-blockers. Only long-acting CCBs should be used:
  - Dihydropyridine CCBs: Nifedipine (30 to 90 mg/day), amlodipine (5 to 10 mg/day), or felodipine (2.5 to 10 mg/day) work predominantly on arterial vasodilation and can improve coronary blood flow.
  - Nondihydropyridine CCBs: Diltiazem (120 to 480 mg/day) or verapamil (120 to 480 mg/day) also have negative inotropic effects and should not be used in those with ejection fraction <40% because they may precipitate heart failure. Side effects include constipation and peripheral edema.

- **Nitrates:** dilate systemic veins and arteries (including coronary vessels) and cause decreased preload. At higher doses, they decrease BP.
  - Sublingual nitroglycerin (0.4 mg every 5 minutes for up to 3 doses) used for acute anginal episodes
  - Long-acting nitrates such as isosorbide mononitrate (30 to 240 mg daily [extended release]) can be used for angina prophylaxis.
  - Side effects include headache and hypotension but tend to improve with continued usage.
  - Contraindicated with concomitant phosphodiesterase type 5 inhibitor use (e.g., sildenafil)

- **Lipid-lowering agents:**
  - High-intensity statin therapy is indicated for all patients with CAD regardless of lipid levels.
  - Statin therapy should also be strongly considered for those with high CAD risk (lifetime ASCVD risk ≥7.5–10%, <75 to 80 years. Evidence for benefit is sparse for statins in primary prevention after 75 years.).
  - Atorvastatin (40 to 80 mg/day) and rosuvastatin (20 to 40 mg/day) are high-intensity statins.
  - Statins reduce risk of MI and revascularization need. Side effects include myalgias, transaminitis, rhabdomyolysis (rare), and impaired glucose tolerance.
  - Ezetimibe may be added to statin therapy if LDL is not at goal after maximally tolerated dose of statin, especially in secondary prevention.
  - Proprotein convertase subtilisin/kexin type 9 inhibitors further reduce LDL levels when used in combination with statins for high-risk patients and reduce cardiovascular events in highly selected patients but are very expensive.

- **Antiplatelets:** decrease risk of thrombosis
  - Aspirin (75 to 162 mg/day) decreases risk of first MI and reduces adverse cardiovascular
events in those with stable angina.
- Clopidogrel (75 mg/day) may be used in patients with contraindications to aspirin.
- Dual antiplatelet therapy with aspirin + clopidogrel, prasugrel, or ticagrelor is indicated after MI or percutaneous coronary intervention (PCI) (use prasugrel only after PCI. Do not use in patient with CVA history).

- Angiotensin-converting enzyme inhibitors (ACEIs): act on the renin-angiotensin-aldosterone system to reduce BP and afterload. They also have effects on cardiac remodeling after MI.
  - ACEIs such as lisinopril (5 to 40 mg/day) and enalapril (2.5 to 20.0 mg BID) have been shown to reduce both cardiovascular death and MI in patients with CAD and left ventricular systolic dysfunction.
  - Angiotensin receptor blockers such as candesartan (4 to 32 mg daily) may be used in patients intolerant to ACEIs.
  - Side effects include cough (ACEIs predominantly), hyperkalemia, and angioedema.

**Second Line**
Ranolazine (500 to 1,000 mg BID) decreases calcium overload in myocytes, acting as an antianginal/anti-ischemic agent.

- Does not affect heart rate or BP
- Use as adjunctive therapy when symptoms persist despite optimal doses of other antianginals
- Side effects can include nausea, constipation, dizziness, QT prolongation, and headache.

**SURGERY/OTHER PROCEDURES**
- Revascularization should be considered if optimal medical therapy is inadequate to control symptoms.
- PCI with balloon angioplasty and/or stent placement (with drug-eluting or bare-metal stent) is performed for significant lesions. Additional techniques include laser therapy and atherectomy.
- Current literature does not show that PCI decreases mortality or risk of MI versus aggressive medical management in those with stable angina.
- Coronary artery bypass graft (CABG) is preferred over PCI for those with severe left main coronary stenosis, significant lesions in ≥3 major coronary arteries, and for lesions not amenable to PCI.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Relaxation/stress reduction therapy for angina

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Lifestyle modifications should be aggressively stressed at every visit.

**Patient Monitoring**
Frequent follow-up after initial event: every 4 to 6 months in first year and then 1 to 2 times per year

**DIET**
- Reduced intake of trans-fatty acids
Adherence to dietary modification for comorbid conditions (diabetes, heart failure, hypertension)

**PROGNOSIS**
Variable; depends on severity of symptoms, extent of CAD, and left ventricular function

**COMPLICATIONS**
ACS, arrhythmia, cardiac arrest, heart failure

**REFERENCES**

**SEE ALSO**
Algorithm: Chest Pain/Acute Coronary Syndrome

**CODES**

**ICD10**
- I25.119 Athscl heart disease of native cor art w unsp ang pctrs
- I25.118 Athscl heart disease of native cor art w oth ang pctrs
- I20.9 Angina pectoris, unspecified

**CLINICAL PEARLS**
- Maximize antianginal therapy: Combine β-blockers, CCBs, and nitrates as tolerated, along with high-intensity statin therapy. PCI may be considered for those with stable ischemic heart disease who continue to have angina on maximally tolerated medical therapy. PCI is first-line treatment for those with unstable angina/NSTEMI/STEMI.
- Lifestyle changes and optimal medical therapy must be emphasized to prevent progression of atherosclerosis and to control contributing risk factors.
COSTOCHONDRITIS
Smriti Ohri, MD • Scott A. Fields, MD, MHA

BASICS

DESCRIPTION
- Anterior chest wall pain and tenderness of the costochondral and costosternal regions, most often affecting the 2nd to the 5th costal cartilages
- System(s) affected: musculoskeletal
- Synonym(s): costosternal syndrome; parasternal chondrodynia; anterior chest wall syndrome

EPIDEMIOLOGY
- Predominant age: 20 to 40 years
- Predominant gender: female

Incidence
- 30% emergency room visits for chest pain
- 13% primary care visits for chest pain

ETIOLOGY AND PATHOPHYSIOLOGY
Although not fully understood, inflammation can be caused by pulling from adjoining muscles at costochondral or costosternal regions.

RISK FACTORS
- Unusual physical activity or upper extremity overuse
- Recent trauma (including motor vehicle accident, domestic violence) or new-onset physical activity
- Recent upper respiratory infection (URI) with coughing

DIAGNOSIS
- Pain is usually sharp, achy, or pressure-like, involving multiple (and mostly unilateral 2nd to 5th) costal cartilages.
- Exacerbated by upper body movements and exertional activities
- Reproduced by palpation of the affected cartilage segments
- Chest tightness is often associated with the pain.

HISTORY
- A complete and thorough history (including a cardiac risk factor evaluation) is mandatory for the diagnosis.
- Social history: careful screening and evaluation for domestic violence and substance abuse

PHYSICAL EXAM
- A thorough cardiopulmonary exam to exclude other conditions presenting with chest pain
  - Cardiac rhythm; murmurs; gallops, rubs
  - Adventitious lung sounds—rales, rhonchi, wheezes, rubs
Tenderness over the costochondral junctions is necessary to establish the diagnosis but does not completely exclude other causes of chest pain.

If swelling or redness of costal cartilage is present, the presentation is often termed Tietze syndrome.

Movement of upper extremity of the same side may reproduce the pain.

Abdominal exam: tenderness, masses, organomegaly

**Pediatric Considerations**
- Consider psychogenic chest pain in children who perceive family discord.
- Consider slipping rib syndrome in children with chronic chest and abdominal pain (1).

**Geriatric Considerations**
Consider herpes zoster in elderly patients.

**DIFFERENTIAL DIAGNOSIS**

- **Cardiac**
  - Coronary artery disease (CAD)
  - Cardiac contusion from trauma
  - Aortic aneurysm
  - Pericarditis
  - Myocarditis
- **Gastrointestinal**
  - Gastroesophageal reflux
  - Peptic esophagitis
  - Esophageal spasm
  - Cholecystitis
- **Musculoskeletal (1)**
  - Fibromyalgia
  - Slipping rib syndrome
  - Costovertebral arthritis
  - Painful xiphoid syndrome
  - Rib trauma
  - Ankylosing spondylitis
- **Psychogenic**
  - Panic attacks
  - Hyperventilation
- **Respiratory**
  - Asthma
  - Pulmonary embolism
  - Pneumonia
  - Chronic cough
  - Pneumothorax
- **Other**
  - Domestic violence and abuse
  - Herpes zoster
  - Spinal tumor
  - Metastatic cancer
– Substance abuse (cocaine)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Primarily a clinical diagnosis
- Laboratory exams and imaging to rule out other diagnoses
- ESR is inconsistently elevated.

**Initial Tests (lab, imaging)**

Imaging is not indicated for the diagnosis of costochondritis.

**Diagnostic Procedures/Other**

- None indicated for the diagnosis of costochondritis
- Consider ECG in patients age >35 years and for patients with history of or at risk for CAD [2][C].
- Consider chest x-ray in patients with appropriate cardiopulmonary symptoms [2][C].
- Consider CT imaging if high suspicion of infectious or neoplastic process [2][C].
- Consider spiral CT for pulmonary embolism and D-dimer if history or risk factors are present.

**Test Interpretation**

Costochondral joint inflammation

**TREATMENT**

Reassurance of benign nature of condition and potential for long, slow recovery from pain

**GENERAL MEASURES**

- Rest and heat (or ice) massage
- Stretching exercises
- Minimize symptom-provoking activities (e.g., reduce frequency or intensity of exercise/work activity).

**MEDICATION**

- Pain relief with NSAIDs (ibuprofen, naproxen, or diclofenac), acetaminophen or other analgesics
- Use of skeletal muscle relaxants may be beneficial if associated with muscle spasm.

**ISSUES FOR REFERRAL**

- Consider referral to physical therapy for pain reduction and improvement in function [3][B].
- Refractory cases of costochondritis can be treated with local injections of combined lidocaine/corticosteroid into costochondral areas; rarely necessary [2][C]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Limited data but may be safely tried if patient interested

- Chiropractic manipulation; exercise prescription
- Dry needling by properly trained providers [4][C]
- Acupuncture [5][C]
- Massage

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Only if differential diagnosis is unclear and cardiac or other serious etiology of chest pain is being considered

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up within 1 week if diagnosis is unclear or symptoms do not abate with conservative treatment

**PATIENT EDUCATION**
- Educate regarding the self-limited (although potentially recurrent) nature of the illness.
- Instruct patient on proper physical activity regimens to avoid overuse syndromes.
- Avoid sudden, significant changes in activity.

**PROGNOSIS**
- Self-limited illness lasts for weeks to months and usually abates by 1 year: sometimes chronic particularly in adolescents
- Often recurs

**COMPLICATIONS**
Incomplete attention to differential diagnosis or overly aggressive interventions to ensure a more life-threatening diagnosis is not missed

**REFERENCES**

**CODES**

**ICD10**
M94.0 Chondrocostal junction syndrome [Tietze]

**CLINICAL PEARLS**
- A common disorder, accounting for up to 30% of all cases of chest pain
- Diagnosis is primarily clinical. Lab and other testing is done to exclude other conditions based
on patient risk.

- Self-limited (potentially recurrent) condition. Activity modification helps prevent recurrence.
COUNSELING TYPES
William T. Garrison, PhD

BASICS

DESCRIPTION
- Psychotherapeutic and counseling interventions play an important role in the management of chronic and acute-onset diseases and disorders. They are typically the primary initial mode of evaluation and/or treatment for most mild to moderate psychiatric disorders that reach criteria using the DSM-5 (1) or ICD-10 (2) diagnostic classification systems. Treatment and successful control of either medical or psychological conditions typically benefit from some form of professional counseling. Best outcomes occur when they are employed by a skilled practitioner. However, psychotherapy differs from generic counseling, which can take many forms and is delivered commonly in nonmedical settings. In recent years, attempts to integrate counseling and psychotherapy within primary care practices have increased.
- Counseling approaches are usually tailored to the specific presenting problem or issue and serve educational and emotional support functions. Typically, counseling in medical settings will be time-limited and problem-focused and often not intended to lead to major medical symptom relief or major behavioral changes, but to improve patient coping.
- The goals of psychotherapy range from increasing individual psychological insight and motivation for change to reduction of interpersonal conflict in the marriage or family, reduction of chronic or acute emotional suffering, or reversal of dysfunctional or habitual behaviors. There are several general classes of psychotherapy, starting with individual, marital, or family approaches. In addition, a number of psychological theories guide various methods and treatment philosophies. The following is a brief overview of commonly used psychotherapeutic and counseling methods.
  - Psychodynamic therapy: Unconscious conflict manifests as patient’s symptoms/problem behaviors:
    o Short-term (4 to 6 months) and long-term (≥1 year)
    o Focus is on increasing insight of underlying conflict or processes to initiate symptomatic change.
    o Therapist actively helps patient identify patterns of behavior stemming from existence of an unconscious conflict or beliefs and motivations that may not be accurately perceived by the individual.
  - Cognitive-behavioral therapy (CBT): Patterns of thoughts and behaviors can lead to development and/or maintenance of symptoms. Thought patterns may not accurately reflect reality and may lead to psychological distress:
    o CBT aims at modifying thought patterns by increasing cognitive flexibility and changing dysfunctional behavioral patterns.
    o CBT encourages patient self-monitoring of symptoms and the precursors or results of maladaptive behavior.
    o CBT uses therapist-assisted challenges to patient’s basic beliefs/assumptions.
    o May use exposure, a procedure derived from basic learning theories, which encourages gradual steps toward change, at a speed that is tolerated by the patient.
    o CBT can be offered in group or individual formats, for adults or children.
A CBT practitioner attempts to combine practical interventions with emotional supports.

- Dialectical behavior therapy (DBT): Techniques such as social skills training, mindfulness, and problem solving are used to modulate impulse control and affect management:
  - DBT is a therapy approach that derives from CBT, but emphasizes emotional control in relationships
  - Originally used in treatment of patients with self-destructive behaviors (e.g., cutting, suicide attempts)
  - Seeks to change rigid patterns of cognitions and behaviors that have been maladaptive
  - Uses both individual and group treatment modalities
  - The DBT therapist takes an active role in interpretation and support.

- Interpersonal psychotherapy: Interpersonal relationships in a patient’s life are linked to symptoms. Therapy seeks to alleviate symptoms and improve social adjustment through exploration of patient’s relationships and experiences. Focus is on one of four potential problem areas:
  - Grief or loss
  - Interpersonal role disputes
  - Role transitions
  - Interpersonal deficits: Therapist works with the patient in resolving the problematic interpersonal issues to facilitate change in symptoms.

- Family therapy: focuses on the family as a unit of intervention
  - Uses psychoeducation to increase patient’s and family’s insight
  - Teaches communication and problem-solving skills

- Motivational interviewing (MI): focuses on motivation as a key to successful change process
  - Short-term and problem-focused. Many therapists use MI prior to initiating other therapies
  - Focuses on identifying discrepancies between goals and behavior, and the patient’s desire to change
  - “5 A’s” model is a brief counseling framework developed specifically for physicians to effect behavioral change in patients:
    ■ Assess for a problem.
    ■ Advise making a change.
    ■ Agree on action to be taken.
    ■ Assist with self-care support to make the change.
    ■ Arrange follow-up to support the change.

- Supportive and informational counseling (heterogeneous treatment)
  - Often focuses on situational factors maintaining symptoms
  - Often encourages the use of community resources

- Behavioral therapy: relatively nontheoretical approach to behavioral change or symptom reduction/eradication through application of principles of stimulus and response. Motivational interviewing is often performed at the onset of behavioral and parenting counseling or therapy.

**Pediatric Considerations**

- Important distinctions are made between psychotherapy and counseling for children/teens compared to adults/couples.
- The focus of evaluation must include attention to parent and family processes and factors. Interventions typically include interactions and sessions with parents as well as collateral work.
with teachers and other school personnel.

- Younger children will often be evaluated and diagnosed through behavioral descriptions provided by parents and other adults who know them well as well as through direct observation and/or play techniques. Children of all ages should be screened using behavioral checklists that are standardized and norm-referenced for age.
- Any child or teenager who requests counseling should be interviewed initially by the primary care provider and referred appropriately. Most referrals will be in response to parental request, however.
- Psychotherapeutic interventions with the strongest empirical basis with children include behavior therapy/modification, CBT, and family/parenting therapy. Play therapy has the least empirical support but has been found to be useful for developing rapport and for treating trauma in younger children. Insight-oriented therapies appear to be more effective with older children (10 years or older).
- There is controversy regarding the efficacy of psychopharmacologic treatment in preadolescents, although clear benefits have been demonstrated in some studies as well as clinical practice. Treatment guidelines for mild to moderate depressed mood and/or anxiety disorders typically recommend pediatric CBT initially, and studies have typically supported this approach in preteen and milder cases. Medications should be considered in more severe presentations.

EPIDEMIOLOGY

- 19 million adults suffer from clinical depression, and over 20 million adults have a diagnosable anxiety disorder in the U.S.
- One in four Americans report seeking some form of mental health treatment in their adult life. This includes generic counseling in nonmedical settings such as work, clergy, or school settings and also includes visits to primary care providers. It is estimated that between 3.5% and 5% of adults in the United States participate in formal mental health psychotherapy annually.
- Public health experts report that the majority of those adults with diagnosable psychiatric disorders do not receive professional mental health services. This is due to multiple factors, including failure to identify, noncompliance with psychiatric referral, regional shortages of providers, economic or insurance barriers, and excessive time duration from referral to an available service.

RISK FACTORS

The need for psychotherapy or counseling services is associated with a host of socioeconomic and biogenetic factors, including the general effects of poverty, family or marital dysfunction, life stressors, medical diseases or conditions, and individual biologic predisposition to mental health disorders.

GENERAL PREVENTION

It is generally assumed that early identification and intervention of child and adolescent psychopathology increases the likelihood of reducing the risk for adult psychopathology, but this has not been sufficiently validated in all categories of psychological disorders. Data support such claims in disorders such as childhood ADHD, anxiety disorders, and habit disorders of childhood, however. A range of evidence-based therapies now exist that are designed for children and adults.
TREATMENT

GENERAL MEASURES
There is evidence of a “dose effect” in psychotherapy outcomes research, with some investigators suggesting that 6 to 8 sessions are necessary to yield positive initial effects in adults, and upward of 15 to 20 sessions for longer term, sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Also, long-term therapy should be evaluated at 3- to 6-month intervals to determine efficacy.

MEDICATION
- Psychotherapy is most likely to be accompanied by use of pharmaceutical adjuncts in moderate to severe cases of psychological dysfunction that do not respond to other therapies or in cases of extremely poor quality of life or high risk. The most common examples are in cases of clinical depression or anxiety that clearly incapacitates the patient or significantly reduces his or her quality of life. Patients at risk for suicide or who represent a danger to others are also candidates for acute psychopharmacotherapy. Studies suggest that verbal and behaviorally oriented therapies can add efficacy to medication treatment in both depression and anxiety, and reduce the risk of relapse.
- There is controversy in the research field regarding the efficacy of medication alone versus psychotherapy alone versus combined treatments. The most recent consensus has been that combined treatments in moderate to severe psychological dysfunction are most likely to render positive short-term results and increase the likelihood that such effects can be sustained over time. Many patients in mental health settings do not require psychotropic medications.

ADDITIONAL THERAPIES
- Anxiety disorders
  - Panic disorder with and without agoraphobia: CBT, psychodynamic therapy
  - Generalized anxiety disorder: CBT
  - Obsessive-compulsive disorder: CBT
  - Posttraumatic stress disorder: CBT, play therapy with children
  - Specific phobia: CBT
  - Social phobia: CBT
- Mood disorders
  - Unipolar depression: CBT, interpersonal therapy, psychodynamic therapy
  - Bipolar disorder: family therapy, interpersonal therapy, CBT/DBT
  - Schizophrenia: psychodynamic therapy, family therapy, CBT/DBT
- Eating disorders
  - Binge eating disorder: CBT/DBT, interpersonal therapy, behavior modification
  - Bulimia nervosa: CBT/DBT, interpersonal therapy, behavior modification
- Personality disorders
  - Borderline: DBT, CBT
- Substance-use disorders
  - Alcohol: counseling, CBT, motivational interviewing
  - Cocaine, Heroin, Opioids, Cannabis: CBT, counseling
  - Smoking: Motivational interviewing, behavioral modification with evidence based
medications

COMPLEMENTARY & ALTERNATIVE MEDICINE
A host of nonempirically based psychological and nutritional therapies can be found outside of mainstream medicine and psychological science. Very little or no evidence exists to support many experimental therapies, but all have the considerable power of the placebo effect fueling their anecdotal supports or claims. Placebo effects are also thought to be powerfully enhanced by the use of ingested or applied substances that create real physiologic, although not therapeutic, changes in the patient. If it makes them feel different, they are more likely to believe it helps. Placebo alone accounts for moderate amounts of perceived symptom improvement in a range of psychiatric medications.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
There is evidence of a “dose effect” in psychotherapy outcomes research, with investigators suggesting upward of 20 sessions for sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Because many patients cease attendance to psychotherapy sessions after one or a few sessions, most interventions of this type cannot be accurately evaluated by the referring provider. Long-term therapy should also be evaluated for effectiveness at regular periods.

REFERENCES

ADDITIONAL READING
CODES

ICD10
- Z71.9 Counseling, unspecified
- Z71.89 Other specified counseling
- Z63.9 Problem related to primary support group, unspecified

CLINICAL PEARLS

- Combined medication and psychotherapeutic treatments in moderate to severe psychological dysfunction are most likely to render positive short-term results and increase the likelihood such effects can be sustained over time.
- Relapse is common over time and/or as treatments are discontinued or not re-evaluated.
- Children <10 years may benefit significantly from counseling or behavior therapy alone for symptom relief.
- Older children and those with more severe symptoms typically require psychopharmacologic options in concert with counseling and/or cognitive-behavioral therapy approaches.
CROHN DISEASE
Eric J. Mao, MD • Samir A. Shah, MD, FACG, FASGE, AGAF

BASICS

DESCRIPTION
A chronic, relapsing inflammatory gastrointestinal (GI) tract disorder, most commonly involving the terminal ileum (80%)
• Hallmark features of Crohn disease (CD)
  – Transmural inflammation that can result in fibrotic strictures, fistulae, fissures, or abscesses
  – Noncaseating granulomas (30%)
  – Skip lesions: segmental disease distribution interspersed with normal mucosa; can also be continuous, mimicking ulcerative colitis (UC)
  – Diverse presentations: ileitis (1/3), ileocolitis (1/3); isolated colitis (1/3)
• Early disease
  – Ulcerations: focal lesions with surrounding edema, resembling aphthous ulcers
  – Perianal disease (pain, anal fissures, perirectal abscess) may precede intestinal disease.
  – May present as wasting illness or anorexia
• Developed disease
  – Mucosal cobblestoning; luminal stenosis; creeping fat; fissures between mucosal folds result in strictures or fistulae.

EPIDEMIOLOGY

Incidence
• 3 to 20 cases per 100,000 person-years in North America; incidence rising globally
• Bimodal age distribution: Predominant age is 15 to 30 years, with a second smaller peak at 50 to 80 years.
• Women slightly more affected than men; increased incidence in northern climates
• Increased risk in whites versus nonwhites: 2- to 5-fold
• Increased risk in Ashkenazi Jews: 3- to 5-fold

Prevalence
247 cases per 100,000 persons

ETIOLOGY AND PATHOPHYSIOLOGY

General: Clinical manifestations result from activation of inflammatory cells and subsequent tissue injury.
• Mechanism of diarrhea: excess fluid secretion and impaired absorption; bile salt malabsorption in inflamed ileum; steatorrhea; bacterial overgrowth
• Multifactorial: Genetics, environmental triggers, commensal microbial antigens, and immunologic abnormalities result in inflammation and tissue injury.

Genetics
• 15% of CD patients have a first-degree relative with inflammatory bowel disease (IBD); first-degree relative of an IBD patient has 3- to 30-fold increased risk of developing IBD by age 28 years; >200 genes associated with IBD; >71 CD genes
- Mutations in susceptibility loci
  - Ileal CD: IBD1 gene, NOD2
  - Early-onset CD (age ≤15 years): 5q31–33 (IBD5), 21q22, and 20q13
  - Extraintestinal manifestations of CD: mutations in HLA-A2, HLA-DR1, HLA-DQw5
  - Others: IL-10, IL-23 receptors, ATG16L1, IRGM
- Associated genetic syndromes: Turner and Hermansky-Pudlak syndromes, glycogen storage disease type 1b

**RISK FACTORS**

Environmental factors
- Cigarette smoking doubles the risk of CD; tobacco cessation reduces flares and relapses.
- Dietary factors: higher incidence if diet high in refined sugars, animal fat, protein (meat, fish)
- Salmonella or Campylobacter increases risk of developing IBD.
- Clostridoides difficile infection may trigger flare and make treatment more difficult.

**COMMONLY ASSOCIATED CONDITIONS**

- Extraintestinal manifestations
  - Arthritis (20%): seronegative, small and large joints; ankylosing spondylitis (AS) and sacroilitis (SI)
  - Skin disorders (10%): erythema nodosum, pyoderma gangrenosum, psoriasis
  - Ocular disease (5%): uveitis, iritis, episcleritis
  - Kidney stones: calcium oxalate stones (from steatorrhea and diarrhea) or uric acid stones (from dehydration and metabolic acidosis)
  - Fat-soluble vitamin deficiency (A, D, E, K)
  - Osteopenia and osteoporosis; hypocalcemia
  - Hypercoagulability: venous thromboembolism prophylaxis essential in hospitalized patients
  - Gallstones: cholesterol stones resulting from impaired bile acid reabsorption
  - Primary sclerosing cholangitis (5%): more common in men with UC; asymptomatic, elevated alkaline phosphatase as marker; increased colon cancer risk (annual colonoscopy)
  - Autoimmune hemolytic anemia
- Conditions associated with increased disease activity
  - Peripheral arthropathy (not SI and AS)
  - Episcleritis (not uveitis)
  - SI, AS, and uveitis are associated with HLA-B27.
  - Oral aphthous ulcers and erythema nodosum
  - Other complications: GI bleed, toxic megacolon, bowel perforation, peritonitis, malignancy, rectovaginal fistula

**DIAGNOSIS**

**HISTORY**

Hallmarks: fatigue, fever, weight loss, prolonged diarrhea, perianal disease, crampy abdominal pain (+/− bleeding). Children may present with failure to thrive.
- Factors exacerbating CD: concurrent infection, smoking, nonsteroidal anti-inflammatory drugs, antibiotics, stress

**PHYSICAL EXAM**
Presentation varies with location of disease.
- General: signs of sepsis/disease activity (fever, tachycardia, hypotension) or wasting/malnutrition
- Abdominal: focal or diffuse tenderness, distension, rebound/guarding, rectal bleeding, palpable mass
- Perianal: fistulae, fissures
- Skin: erythema nodosum; psoriasis

**DIFFERENTIAL DIAGNOSIS**
- Acute, severe abdominal pain: perforated viscus, pancreatitis, appendicitis, diverticulitis, bowel obstruction, kidney stones, ovarian torsion
- Chronic diarrhea with crampy pain (colitis-like): UC, radiation colitis, infection, drugs, ischemia, microscopic colitis, IBD, celiac disease, malignancy (lymphoma, carcinoma), carcinoid
- Wasting illness: malabsorption, malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Complete blood count (CBC), serum chemistries, liver function tests (LFTs), erythrocyte sedimentation rate, C-reactive protein, serum iron, vitamin B₁₂, vitamin D-25 OH, stool calprotectin
- If diarrhea, stool specimen for routine culture, C. difficile, and ova and parasites
- With severe flares, kidney, ureter, bladder to rule out toxic megacolon
- Ileocolonoscopy provides the greatest diagnostic sensitivity and specificity; biopsy normal and abnormal mucosa (1)[C]
- Upper endoscopy for patients with upper GI signs or symptoms (1)[C]
  - Signs of upper GI CD: antral narrowing, segmental stricturing, inflammatory mucosa
- Small bowel: sensitivity of CT or magnetic resonance enterography (MRE) better than small bowel follow through. MRE has no radiation exposure (important in younger patients).
  - Signs of small bowel disease: narrowed lumen with nodularity (string sign); cobblestone appearance, fistula and abscess formation, bowel loop separation (transmural inflammation)
- Perianal disease: endoscopic ultrasound (EUS) or MRI pelvis with exam under anesthesia
- Contraindications to endoscopy: perforated viscus, recent myocardial infarction, severe diverticulitis, toxic megacolon, or intolerance of bowel preparation
- In most cases, unprepared limited sigmoidoscopy allows adequate visualization to assess severity, extent, aspirate stool for C. difficile, obtain biopsies to assess histologic severity, and exclude other disorders (e.g., cytomegalovirus) in colonic CD.

**Follow-Up Tests & Special Considerations**

Evidence of complications
- Stricture: obstructive signs—nausea, vomiting, pain, weight loss, diarrhea, or inability to pass gas/feces
- Abscess/inflammatory mass: localized abdominal peritonitis with fever and abdominal pain; diffuse peritonitis suggests perforation or abscess rupture (may be masked by steroids, opiates).
- Fistula:
– Enteroenteric: asymptomatic or a palpable, commonly indolent, abdominal mass
– Enterovesical: pneumaturia, recurrent urinary tract infection
– Retroperitoneal: psoas abscess, ureteral obstruction
– Enterovaginal: vaginal passage of gas or feces; clear, nonfeculent drainage from ileal fistula
  (may be misdiagnosed as primary vaginal infection)

**Diagnostic Procedures/Other**

**How to distinguish CD from UC:**
- CD: small bowel disease, rectal sparing; skip lesions; granulomas, perianal disease, and/or fistulae; no gross bleeding; right lower quadrant pain is common.
- UC: continuous involvement including the rectum; loss of vascularity, friable tissue; left lower quadrant pain; typically only affects colon; rectal bleeding common

**ALERT**
CD can mimic UC with continuous bowel involvement; 10–15% of cases are difficult to differentiate.

**TREATMENT**

- Disease activity: Crohn Disease Activity Index (CDAI)
  - Asymptomatic: spontaneous, after medical/surgical intervention, or while on steroids (CDAI <150)
  - Mild to moderate CD: ambulatory patients able to tolerate PO intake without dehydration, obstruction, or >10% weight loss; no abdominal tenderness, toxicity, or mass (CDAI 150 to 220)
  - Moderate to severe CD: patients who have failed initial treatment or who continue to have mild symptoms such as fever, weight loss, and abdominal pain (CDAI 220 to 450)
  - Severe: persistent symptoms despite therapy with glucocorticoids and/or biologics or fulminant disease (peritonitis, cachexia, intestinal obstruction, abscess) (CDAI >450)
- CD risk stratification for rapidly progressive disease:
  - Risk factors for moderate/high-risk disease: age at diagnosis <30 years, extensive anatomic involvement, perianal or severe rectal disease, deep ulcers, prior surgical resection, strictureing and/or penetrating behavior
  - Low-risk disease: budesonide or prednisone taper with or without immunomodulator
  - Moderate/high-risk disease: biologic monotherapy or biologic combination therapy with immunomodulator

**GENERAL MEASURES**

- Oral lesions: triamcinolone acetonide in benzocaine and carboxymethyl cellulose or topical sucralfate for aphthous ulcers, cheilitis, and/or granulomatous sialadenitis
- Gastroduodenal CD: no clinical trials. Case reports show success of anti-TNF therapies; symptomatic relief possible from proton pump inhibitors, H₂ receptor blockers, and/or sucralfate
- Ileitis: Supplemental fat-soluble vitamins, iron, vitamin B₁₂, folate, and calcium may be necessary.
- Treatment toxicity: pancreatitis, bone marrow toxicity, lymphoma, nonmelanoma and
MEDICATION

First Line
- Asymptomatic with minimal endoscopic disease: observation alone
- Mild CD
  - Mesalamine should not be used to treat active CD (1)[A]
  - Antibiotics not more effective than placebo (1)[C]
  - Induction:
    - Controlled ileal release budesonide (9 mg/day for 8 to 16 weeks and then discontinued over 2- to 4-week taper) for distal ileum and/or right colon involvement (3)[A]
      - Tapering dose of prednisone
    - Maintenance:
      - Stop therapy and observe
      - Immunomodulator therapy
    - Adjunctive therapy: antidiarrheals (loperamide); bile acid–binding resin (cholestyramine 4 to 12 g/day); probiotics (either alone or in combination may reduce inflammation/symptoms in acute CD)
- Moderate to severe CD
  - Induction: biologic as initial induction agent to avoid corticosteroids; controlled-release budesonide (for isolated, moderate ileitis) or prednisone 40 to 60 mg/day for short-term to alleviate symptoms (1)[C]
  - Maintenance: no role for mesalamine. If steroids required for induction, use biologic (3)[B] and/or immunomodulator (3)[B]
  - Except for budesonide, do not use steroids for maintenance (1)[A].
  - Immunomodulators:
    - Thiopurines: azathioprine or 6-mercaptopurine (6MP) for maintenance but not induction (1)[C]: Check thiopurine methyltransferase (TPMT) and LFTs prior to initiation; CBC/LFTs q2–3mo
    - Methotrexate (SC or IM): effective for induction and maintenance of steroid-dependent CD (1)[C]; take with folic acid 1 mg/day; follow LFT, CBC.
  - Anti-TNF: infliximab, adalimumab, certolizumab pegol for induction and maintenance of remission (1)[A]
    - Check for evidence of TB and hepatitis B virus (HBV) infection prior to initiation of anti-TNF therapy.
    - Avoid live vaccines.
    - Monitoring: CBC, LFT, drug levels
  - Combination therapy: anti-TNF and immunomodulator
    - Immunomodulator can be added as adjunctive therapy or to reduce immunogenicity against biologic.
    - Azathioprine + infliximab is more effective than either alone if no previous therapy with either.
    - Rare complication: hepatosplenic T-cell lymphoma (fatal, seen in young males) with thiopurines only
  - Antiadhesion molecules: prevent inflammatory cells from entering GI tract
    - Vedolizumab: gut-selective, used in anti-TNF failures or anti-TNF naive patients as
induction and maintenance; given IV, no risk of progressive multifocal leukoencephalopathy (PML) (1)[B].

Natalizumab: non–gut-selective, used for induction and maintenance (1)[B]; PML risk (1/1,000); can minimize risk by testing for John Cunningham (JC) virus antibody; avoid risk of PML now with vedolizumab.

- Anti–IL-12/IL-23 monoclonal antibody: ustekinumab efficacious in induction and maintenance of remission in anti-TNF naive and anti-TNF failures. Excellent safety profile; monitor CBC and LFTs.
- Therapeutic drug monitoring: Optimize biologics to avoid side effects. Measure trough levels of drug, and if drug not present, assess for antibody to the drug. If low or absent drug level and no antibodies, increase dose or frequency. If no drugs and high antibody levels, switch to a different agent with same or different mechanism. If drug present and no antibodies with active disease, switch to an agent with different mechanism (4)[C].

New/investigational therapies:
- JAK1 kinase selective inhibitor, anti–IL-23 agents, and sphingosine-1-phosphate receptor modulator

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Vaccinations
- Check titers; avoid live vaccines (measles, mumps, and rubella, varicella, Zostavax) in patients on immunosuppressive therapy (steroids, 6MP, azathioprine, methotrexate, or biologics).
- Regardless of immunosuppression: human papillomavirus, influenza, pneumococcal, meningococcal, hepatitis A, B; Tdap; Shingrix for those 50 years or older
- Cancer prevention
  - Colonoscopy with targeted biopsies every 1 to 3 years after 8 to 10 years of CD with colonic involvement; consider chromoendoscopy if available (5)[C].
  - Annual Pap smears if immunocompromised
  - Annual skin exam
- Bone health
  - Calcium and vitamin D supplementation with each course of corticosteroids or if vitamin D deficient
  - Bone density assessment if previous steroid use, maternal history of osteoporosis, malnourished, amenorrheic, postmenopausal

PATIENT EDUCATION
Crohn’s and Colitis Foundation: (800) 932-2423; https://www.crohnscolitisfoundation.org

COMPLICATIONS
- Peritonitis: bowel rest and antibiotic therapy (7 to 10 days of parenteral antibiotics, followed by 2- to 4-week course of PO ciprofloxacin and metronidazole); surgery as indicated
  - Consider holding steroids which masks sepsis.
- Abscess: antibiotics, percutaneous drainage, or surgery with resection of affected segments
- Small bowel obstruction: IV hydration, nasogastric (NG) tube for decompression, total
parenteral nutrition (TPN) for malnutrition, resolution typically in 24 to 48 hours; surgery for nonresponders

REFERENCES

CODES

ICD10
- K50.919 Crohn’s disease, unspecified, with unspecified complications
- K50.00 Crohn’s disease of small intestine without complications
- K50.10 Crohn’s disease of large intestine without complications

CLINICAL PEARLS

- Cigarette smoking doubles the risk of CD; tobacco cessation reduces flares and need for surgery.
- MRE allows assessment of luminal and extraluminal CD without radiation exposure.
- Assess for TB and HBV infection prior to initiating anti-TNF therapy.
- Test for C. difficile infection when evaluating diarrhea in all CD patients.
- Hospitalized CD patients require deep vein thrombosis prophylaxis.
- Anti-TNF therapy effective in delaying or preventing postoperative recurrence in CD
CROUP (LARYNGOTRACHEOBRONCHITIS)
Mark T. Nadeau, MD, MBA  Olga L. Nunez, MD

BASICS

DESCRIPTION
- The term croup is used to refer to viral laryngotracheitis or laryngotracheobronchitis (LTB). It is a common viral illness presenting with upper airway inflammation and obstruction causing pathognomonic barking cough and inspiratory stridor. In addition, it presents with nonspecific symptoms such as cough, coryza, rhinorrhea, and fever. Symptoms are worse during the night and can rapidly fluctuate depending on whether the child is calm or agitated.
- Spasmodic croup is a noninfectious form with sudden resolution that is usually self-limiting; it is treated like croup and resolves with mist therapy at home.

EPIDEMIOLOGY
- Croup is typically self-limited and it affects approximately 3% of children 6 months to 3 years of age with a peak around the 2nd year of life.
- The vast majority are consider mild cases; however, croup accounts for 5% of annual hospitalization.
- Less than 3% require intubation.
- Predominant sex: male > female (1.5:1)
- Timing
  - Possible during any time of year but is most common during the fall and winter
  - Human parainfluenza 1 and respiratory syncytial virus (RSV) are the most common viral causes.

Incidence
- Six cases per year per 100 children <6 years old
- 1.5–6% of cases require hospitalization.
- 2–6% of those require intubation.
- 60% of barking cough resolved within 48 hours and only 2% have symptoms persisting for longer than 5 nights.

ETIOLOGY AND PATHOPHYSIOLOGY
- Subglottic region/larynx is entirely encircled by the cricoid cartilage.
- Inflammatory edema and subglottic mucus production decrease airway radius.
- Small children have small airways with more compliant walls.
- Negative-pressure inspiration pulls airway walls closer together.
- The anatomically small airway is more susceptible to compromise and narrowing caused by the combined edema, mucus secretions, and increased compliance. Small decrease in airway radius causes significant increase in resistance (Poiseuille law: resistance proportional to 1/radius⁴).
- Typically caused by viruses that initially infect oropharyngeal mucosa and then migrate inferiorly
  - Parainfluenza virus
    - Most common pathogen: 75% of cases
- Type 1 is the most common, causing 18% of all cases of croup.
- Types 2, 3, and 4 are also common.
- Type 3 may cause a particularly severe illness.

- Other viruses: RSV, paramyxovirus, influenza virus type A or B, adenovirus, rhinovirus, enteroviruses (coxsackie and echo), reovirus, measles virus where vaccination not common, and metapneumovirus
- Haemophilus influenzae type B now rare with routine immunization
- May have bacterial cause: Mycoplasma pneumoniae has been reported.

**RISK FACTORS**
Prior intubations, prematurity, and age younger than 3 years increase the risks for recurrent croup (more than two episodes per year).

**GENERAL PREVENTION**
There is not a specific vaccine for croup, but seasonal influenza shots may contribute to decreased risk.

**COMMONLY ASSOCIATED CONDITIONS**
- If recurrent (>2 episodes in a year) or during first 90 days of life, consider host factors.
- Underlying anatomic abnormality (e.g., subglottic stenosis)
- Paradoxical vocal cord dysfunction
- Gastroesophageal reflux disease
- Neonatal intubation

**DIAGNOSIS**
- Croup is a clinical diagnosis, most children who present with acute onset of barky cough, inspiratory stridor, hoarseness, and chest wall indrawing can be diagnosed with croup; lab tests and imaging serve only ancillary purposes.
- Classic “seal-like” barking, spasmodic cough
- Biphasic stridor
- Low to moderate grade fever
- Upper respiratory infection prodrome lasting 1 to 7 days
- Severity is determined by clinical inspection for signs of respiratory distress like nasal flaring, retractions, tripoding, sniffing position, abdominal breathing, and tachypnea. Although uncommon, if present, hypoxia, cyanosis, and fatigue are late sings of severity.
- Westley Croup Severity Score is most useful for research purposes. It looks at five clinical features: level of consciousness, cyanosis, stridor, air entry, and retractions (≤2 mild; 3 to 7 moderate; ≥8 severe).
  - Level of consciousness: normal, including sleep = 0; disoriented = 5
  - Cyanosis: none = 0; with agitation = 4; at rest = 5
  - Stridor: none = 0; with agitation = 1; at rest = 2
  - Air entry: normal = 0; decreased = 1; markedly decreased = 2
  - Retractions: none = 0; mild = 1; moderate = 2; severe = 3
- Assessment of the severity of croup
  - Mild (0 to 2 Westley): occasional barking cough; no audible stridor at rest, and either mild or no suprasternal or intercostal retractions
- Moderate (3 to 5 Westley): frequent cough, easily audible stridor at rest, and suprasternal and sternal retractions at rest but little or no agitation
- Severe (6 to 11 Westley): frequent barking cough, prominent inspiratory and, occasionally, expiratory stridor, marked sternal retractions, and agitation and distress
- Impending respiratory failure (12 to 17 Westley): barking cough (often not prominent), audible stridor at rest (occasionally hard to hear), sternal retractions (may not be marked), lethargy or decreased level of consciousness, and often dusky appearance in the absence of supplemental oxygen (1)
  - No change in stridor with positioning
  - Nontender larynx
  - Inflamed subglottic region with normal-appearing supraglottic region
  - Differentiate from epiglottitis: Croup presents as non-toxic-appearing, normal voice, no drooling, is coughing (2)

**PHYSICAL EXAM**

Pulse oximetry often is normal because there is no disturbance of alveolar gas exchange.
- Overall appearance: Is the child comfortable or struggling?
- Work of breathing: labored or comfortable?
- Sound of breathing and voice: hoarse, stridor, inspiratory wheezing, short sentences?
- Observed/subjective tidal volume: sufficient for child’s size?

**ALERT**

Decreased breath sounds and respiratory effort may indicate the child is progressing into respiratory failure and less able to mount an effort to move air. Even though there may be less obvious sign of distress, clinicians should not miss the clinically deteriorating patient.

**DIFFERENTIAL DIAGNOSIS**

In order of decreasing frequency:
- Upper respiratory infection, including classic LTB
- Foreign body aspiration but often requires high index of suspicion
- Bacterial tracheitis: high fever, barking cough, respiratory distress, and rapid deterioration
- Retropharyngeal or peritonsillar abscess: similar septic appearance with dysphonia
- Allergic reaction (acute angioneurotic edema) includes spasmodic croup with classic nocturnal exacerbations
- Epiglottitis: associated with rapid onset, high fever, dysphonia, drooling, and prototypical posture of extended chin and leaning forward. However, the incidence of epiglottitis has significantly decreased with widespread vaccination against Haemophilus influenzae being replaced by strep and staph organisms
- Subglottic stenosis
- Trauma
- Hemangioma: stridor worsen with crying
- Airway anomalies (e.g., tracheo-/laryngomalacia)
- Other anatomic obstructions: subglottic hemangioma, subglottic cyst

**DIAGNOSTIC TESTS & INTERPRETATION**

- LTB, LTBP, and LT are clinical diagnoses and usually do not require confirmatory testing.
- If imaging were to be done, posteroanterior and lateral neck films will show funnel-shaped subglottic region with normal epiglottis: “steeple,” “hourglass,” or “pencil point” sign (present
in 40–60% of children with LTB).

- CT may be more sensitive for defining obstruction in an unclear case.
- Patient should be monitored during imaging—airway obstruction may occur rapidly.
- Also evaluate radiographs for:
  - Retropharyngeal abscess: dimensions of the posterior pharynx (should be same anteroposterior width as a contingent vertebral body)
  - Epiglottitis: thumb sign: appearance of a thumb pointing posteriorly, respectively
- Blood work may not be required. White blood cell (WBC) counts may be mildly elevated with a predominance of lymphocytes; an elevated WBC shift to the left (bandemia) would suggest etiology other than LTB, most likely bacterial. Examples of this would be epiglottitis, bacterial tracheitis, and retropharyngeal abscess.
- Microbiologic studies might be used to identify viral strains and specific bacteriologic species in severe presentations or to track epidemiology. H. influenzae and diphtheria as etiologic agents are rarely seen in industrialized countries in the pharynx as the result of immunization practices.
- Rapid antigen or viral culture tests are available in many centers.
  - Guide isolation precautions, not management.
- Laryngoscopy should be reserved for atypical presentations or when alternate diagnosis are suspected.

**Test Interpretation**

- Inflammatory reaction of respiratory mucosa
- Loss of epithelial cells
- Thick mucoid secretions

---

### TREATMENT

Management of croup is based on severity of illness

- Oxygen should be administered to children with hypoxemia or severe respiratory distress.
- Heliox is a helium and oxygen mixture used for respiratory conditions that seems to improves airflow resistance by decreasing gas density. However, data are limited on its benefits.

**GENERAL MEASURES**

- Symptomatic treatment
- Minimize lab tests, imaging, and procedures that upset the child; agitation worsens tachypnea and can be more detrimental than accepting a clinical diagnosis.
- Electrocardiogram monitoring and pulse oximetry
- Pulse oximetry not as sensitive as frequent clinical checks in identifying worsening disease

**MEDICATION**

**First Line**

- Well established in the literature; the cornerstones of treatment are immediate nebulized epinephrine and oral dexamethasone; there is no statistically significant difference between corticosteroids and epinephrine.
- Corticosteroids: Oral corticosteroids should be used in patients with any severity. They provide faster resolution and decrease hospital admission by decreasing laryngeal mucosa edema.
- Dexamethasone is the preferred corticosteroid due to its easy single dosing and ability to give
orally, intramuscularly, and intravenously. It is also the least expensive steroid. Optimal dosage is unclear, but 0.15 to 0.60 mg/kg is the most commonly used range, with 0.60 mg/kg being the most common dose.

- Randomized controlled trials show this begins to improve symptoms within 30 minutes (3)[A] and full effect by 4 hours.
- Other steroids (betamethasone, budesonide (4)[A], prednisolone) are beneficial. In randomized trials comparing prednisolone to dexamethasone, the latter is more commonly used in the emergency department but they have no difference in efficacy in the community.
- Racemic or L-epinephrine (equal efficacy and side effect profiles; L-epinephrine is used for most other hospital purposes and is less expensive) (1)[A]. It is reserved for more severe cases with stridor at rest
  - Racemic epinephrine is dosed at 0.05 mL/kg/dose (max 0.5 mL) of 2.25% solution nebulized in normal saline to total volume of 3 mL. L-epinephrine is dosed at 0.5 mL/kg/dose (max 5 mL) of a 1:1,000 dilution nebulized. Onset of action is within 1 to 5 minutes, and duration is of approximately 2 hours. Repeat as necessary as long as side effects are tolerated. Observe child for 2 hours to ensure no recurrence after epinephrine wears off.
- Antibiotics are not indicated because this is a viral illness.
- Oxygen as needed
- Humidified air shows no clinical benefit

**Second Line**
Oseltamivir for influenza A

**SURGERY/OTHER PROCEDURES**
Intubation rarely is required; tube 0.5 to 1.0 mm smaller than normal
- After trial of medical management, intubation may be required for fatigue caused by work of breathing or obstruction.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient care in mild cases
- In most cases, observation in the ED after medical management is sufficient.
- Admit patients who do not respond to therapy or have recurrent stridor at rest after epinephrine wears off.
- Admit those who have oxygen requirement, pneumonia, or other serious conditions.
- Discharge criteria
  - >2 hours since last epinephrine
  - No stridor at rest, no difficulty breathing
  - Child able to tolerate liquids PO
  - No underlying medical condition
  - Caretakers able to assess changes to clinical picture and reaccess medical care

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Most children with croup do not require specific follow-up; should consider primary care
physician follow-up if patient had stridor for >1 week.

**DIET**
- Liquid diet is most comfortable for the patient and better tolerated.
- Cold liquids are often more soothing.
- Frequent small feedings with increased fluids for mild cases

**PATIENT EDUCATION**
- Croup is usually a self-limited and mild disease, but some children will need more intense medical care in the hospital.
- Generally, be calming and keep your child comfortable. Keep the child cool by dressing lightly and use antipyretics if they are febrile.
- Keep the child well hydrated with ample cool liquids or popsicles.
- Keep the patient quiet; crying may exacerbate symptoms.
- Educate parents about when to seek emergency care if symptoms worsen.
- Provide emotional support and reassurance for the patient.
- Absolute need for medical care:
  - Respiratory distress; rapid breathing; working hard to breathe; prominent chest or neck muscles with each breath
  - The child becomes restless or agitated.
  - The child looks unusually pale.
  - High temperature (fever) lasts longer than 1 to 2 days
- Emergency ambulance if the child is:
  - Blue (cyanosis)
  - Lethargic
  - Struggling to breathe
  - Drooling and unable to swallow

**PROGNOSIS**
- Prognosis is generally good. The few cases that are severe respond to intensive respiratory management.
- Recurrence is rare in viral-mediated disease.
- If croup recurs, consider an anatomic, allergic, or obstructive etiology.

**COMPLICATIONS**
- Rare
- Subglottic stenosis in intubated patients
- Bacterial tracheitis
- Cardiopulmonary arrest
- Pneumonia

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- J05.0 Acute obstructive laryngitis [croup]
- J20.9 Acute bronchitis, unspecified
- J38.5 Laryngeal spasm

**CLINICAL PEARLS**

- LT and LTB outbreaks are most common in fall and winter time for population aged 6 months to 3 years. Symptoms often occur at night.
- Recurrent episodes should be followed up with a search for anatomic or allergic etiology.
- Foundation of treatment is oxygen, oral/IM steroids, and nebulized epinephrine.
- Consider other diagnoses in acute presentations with toxic appearance: epiglottitis, abscess, bacterial tracheitis.
- Be aware of severity should the child become less noisy; less air movement can be sign of respiratory failure.
- Croup is a clinical diagnosis, thus medical management and stabilization of the patient take priority over lab testing or radiographic images.
CRYPTORCHIDISM
Pamela Ellsworth, MD

BASICS

DESCRIPTION
- Incomplete or improper descent of one or both testicles; also called undescended testes (1)
- Normally, descent is in the 7th to 8th month of gestation. The cryptorchid testis may be palpable or nonpalpable.
- Can be congenital or acquired
- Types of cryptorchidism
  - Pre-scrotal: at or above scrotal inlet
  - Abdominal: testis located inside the internal inguinal ring
  - Canalicular: testis located between the internal and external inguinal rings
  - Ectopic: located outside the normal path of testicular descent from abdominal cavity to scrotum; may be ectopic to perineum, femoral canal, superficial inguinal pouch (most common), suprapubic area, or opposite hemiscrotum
  - Retractile: fully descended testis that moves freely between the scrotum and the groin
  - Iatrogenic: Previously descended testis becomes undescended secondary to scar tissue after inguinal surgery, such as an inguinal hernia repair or hydrocelectomy.
- Also may be referred to as palpable versus nonpalpable (1)
- System(s) affected: reproductive
- Synonym(s): undescended testes (UDT)

EPIDEMIOLOGY

Incidence
- Predominant age: newborn, more common in premature newborns
- Predominant sex: male only

Prevalence
- In the United States, cryptorchidism occurs in 1–3% of full-term and 15–30% of premature newborn males (2).
- Spontaneous testicular descent occurs by age 1 to 3 months in 50–70% of full-term males with cryptorchidism.
- Descent at 6 to 9 months of age is rare (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Not fully known
- May involve alterations in
  - Mechanical factors (gubernaculum, length of vas deferens and testicular vessels, groin anatomy, epididymis, cremasteric muscles, and abdominal pressure), hormonal factors (gonadotropin, testosterone, dihydrotestosterone, and müllerian-inhibiting substance [MIS]), and neural factors (ilioinguinal nerve and genitofemoral nerve)
  - Major regulators of testicular descent from intra-abdominal location into the bottom of the scrotum are the Leydig cell–derived hormones, testosterone, and insulin-like growth factor 3 (IGF-3).
– Mutations in the gene for IGF-3 and in the androgen receptor gene have been evaluated as possible causes of cryptorchidism as well as chromosomal alterations (1).
– Environmental factors acting as endocrine disruptors of testicular descent also may contribute to the etiology of cryptorchidism.

Risk of ascent may be as high as 32% in retractile testis.

Genetics
Increased risk of UDT in sons and siblings suggests a genetic etiology.

RISK FACTORS
• Family history of cryptorchidism: highest risk if brother had UDT, followed by uncle and then father
• Low birth weight, prematurity, and small for gestational age are associated with a substantial increase in incidence of cryptorchidism (1). Retractile testes are at increased risk for ascent.
• Maternal smoking and diabetes during gestation associated with increased risk (3)

COMMONLY ASSOCIATED CONDITIONS
• Inguinal hernia/hydrocele
• Abnormalities of vas deferens and epididymis
• Disorders of sexual development (intersex abnormalities)
• Hypogonadotropic hypogonadism
• Germinal cell aplasia
• Prune-belly syndrome
• Meningomyelocele
• Hypospadias
• Wilms tumor
• Prader-Willi syndrome
• Kallmann syndrome
• Cystic fibrosis

DIAGNOSIS

HISTORY
• ≥1 testicles in a site other than the scrotum
• May be an isolated defect or associated with other congenital anomalies

PHYSICAL EXAM
• Performed with warm hands, with child in sitting, standing, and squatting position
• A Valsalva maneuver and applied pressure to lower abdomen may help to identify the testes, especially a gliding testis.
• Failure to palpate a testis after repeated exams suggests an intra-abdominal or atrophic testis.
• An enlarged contralateral testis in the presence of a nonpalpable testis suggests testicular atrophy/absence.
• Testes should be palpated for quality and position at each recommended well-child visit (1) [B].

DIFFERENTIAL DIAGNOSIS
- Retractile testis (hypermobile testis), a normally descended testis that ascends into the inguinal canal because of an active cremasteric reflex (more common in males 4 to 6 years of age)
- Atrophic testis: may occur as a result of neonatal torsion
- Vanished testis may be the result of a lack of development or in utero torsion.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- If only single testis not palpable in an otherwise normal male, no need for lab tests or imaging.
- In phenotypic male newborn with bilateral, nonpalpable UDTs, hormone levels are helpful to determine whether the testes are present outside the scrotum or congenitally absent (1)[A].
  - Luteinizing hormone (LH)
  - Follicle-stimulating hormone (FSH)
  - MIS
  - Testosterone
  - Serum electrolytes
  - Karyotype
- If bilateral nonpalpable testes and presentation >3 months of age, evaluate for disorders of sexual development (4).
- Evaluate for congenital adrenal hyperplasia if there is a possibility of a disorder of sexual development.
- Ultrasound or other imaging modalities should not be performed in the evaluation of boys with cryptorchidism prior to referral to a specialist, as they are rarely needed in decision making (1)[B].

**Follow-Up Tests & Special Considerations**

In newborns and infants <6 months of age, periodic examination to determine if testis is palpable and descended prior to considering further intervention (1)

**Pediatric Considerations**

In the absence of spontaneous testicular descent by 6 months of age (gestational age adjusted), infant should be referred to appropriate specialist, and surgery should be performed within 1 year (1)[B].
- In children with retractile testes, examination should be performed at least yearly to rule out subsequent ascent (1)[B].
- In boys 11 to 30 months of age with unilateral nonpalpable UDT, if the contralateral descended testis is 19 to 20 mm or greater in length measured by caliper, there is a greater likelihood of a vanished/atrophic testis (5)[B].

**Diagnostic Procedures/Other**

Laparoscopy can confirm presence or absence of testis when nonpalpable and can determine the feasibility of performing a standard orchidopexy. It also allows for treatment at the time of diagnosis.

**Test Interpretation**

Higher incidence of carcinoma in UDT and alterations in spermatogenesis. Histologic changes occur by 1.5 years of age and include smaller seminiferous tubules, fewer spermatogonia, and more peritubular tissue (6).
TREATMENT

GENERAL MEASURES
- Rule out retractile testis.
- Appropriate health care: outpatient until surgery is performed
- Administration of chorionic gonadotropin may cause testicular descent in some boys, but this is not recommended. American Urological Association (AUA) guidelines on cryptorchidism do not recommend use of hormonal therapy to induce testicular descent due to low response rate and lack of evidence for long-term efficacy (1).

MEDICATION
- Medical therapy is not indicated in the United States per the AUA guidelines on cryptorchidism 2014 (1).
- The role of adjuvant GnRH in high risk populations (i.e., those males with bilateral undescended testes without normal maturation of gonocytes in Ad spermatogonia on testis biopsy performed at the time of orcidopexy) has been advocated by some, but remains controversial (7).

ISSUES FOR REFERRAL
- ≥1 testes not descended by 6 months age (1)[B]
- Bilateral nonpalpable UDTs (1)
- Newly diagnosed cryptorchidism after 6 months of age (1)[B]

SURGERY/OTHER PROCEDURES
- Reasons to consider: avoids torsion, averts trauma, decreases but does not eliminate risk of malignancy, and prevents further alterations in spermatogenesis
- In the absence of spontaneous testicular descent by 6 months of age (gestational age–adjusted), surgery should be performed within 1 year (1)[B].
- Prepubertal orchidopexy decreases risk of testicular cancer and results in 2- to 6-fold reduction in relative risk compared to postpubertal orchidopexy (1).
- Laparoscopy/abdominal exploration is performed first if testis is nonpalpable.
- If palpable, an inguinal approach is usually performed. If low-lying, a single incision scrotal approach can also be considered but may increase the risk of hernia.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Initial follow-up within 1 month of surgery and periodically thereafter to assess testicular size/growth
- Patients with retractile testes should be examined at least annually to monitor for secondary ascent until testis is no longer retractile (1)[B].

Patient Monitoring
- Patients should be followed after surgery to evaluate testicular growth.
- Testicular tumors occur mainly during or after puberty; thus, these children should be taught self-examination when they are older.
DIET
No restrictions

PATIENT EDUCATION
Discuss with parents about causes, available treatments, and possible effects on patient’s reproductive potential. Increased risk for testicular cancer in this population requires regular self-examination.

PROGNOSIS
- Disorder is usually corrected with surgical therapy; however, there are possible lifelong consequences.
- If testicle is absent or orchiectomy is required, may consider placement of testicular prosthesis.
- Early orchidopexy may decrease risk of testicular damage and risk of malignancy.

COMPLICATIONS
- Paternity rates are similar to the general population for men with a unilateral UDT but are lower (33–65%) for men with bilateral UDT.
- Abnormalities also have been identified in the contralateral descended testis, although less severe.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- Q53.9 Undescended testicle, unspecified
- Q53.10 Unspecified undescended testicle, unilateral
- Q53.20 Undescended testicle, unspecified, bilateral

CLINICAL PEARLS

- If testicular descent does not occur by 6 months of age, it is unlikely to occur. Therefore, refer patients to a specialist if a testis has not descended by 6 months of age.
- Children with bilateral, nonpalpable UDTs require laboratory evaluation to determine if viable testicular tissue is present and to rule out disorder of sexual differentiation.
- Radiologic imaging has no role in the initial evaluation of cryptorchidism.
- The risk of infertility is increased with bilateral UDTs.
CUSHING DISEASE AND CUSHING SYNDROME
Joumana Chaiban, MD, FACE ● Safiya Elahi, MD

BASICS

DESCRIPTION

- Cushing syndrome is defined as excessive glucocorticoid exposure from exogenous (steroid medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.).
- Exogenous intake of steroids is the primary cause of Cushing syndrome.
- Cushing disease—the most common cause of primary Cushing syndrome—is glucocorticoid excess due to excessive adrenocorticotropic hormone (ACTH) secretion from a pituitary tumor.
- System(s) affected: endocrine/metabolic, musculoskeletal, skin/exocrine, cardiovascular; neuropsychiatric

Pediatric Considerations

- Rare in infancy and childhood
- Cushing disease accounts for approximately 75% of all cases of Cushing syndrome in children >7 years.
  - Rarely, Cushing disease (ACTH-producing pituitary adenoma) can be the initial manifestation of multiple endocrine neoplasia type 1 in pediatric patients.
- In children <7 years, adrenal causes of Cushing syndrome (adenoma, carcinoma, or bilateral hyperplasia) are more common.
- The most common presenting symptom is lack of growth and weight gain.

Pregnancy Considerations

- Pregnancy may exacerbate the disease.
- Cortisol levels increase in normal pregnancy (refer to the “Alert” section in this chapter for further information).

EPIDEMIOLOGY

Incidence

Endogenous causes of Cushing syndrome are extremely rare. They are estimated at around 8 cases per U.S. million population.

Prevalence

2–5% prevalence reported in difficult-to-control diabetics with obesity and hypertension (HTN)

ETIOLOGY AND PATHOPHYSIOLOGY

- General population
  - Exogenous glucocorticoids
  - Endogenous glucocorticoid secretion
    - Endogenous ACTH–dependent hypercortisolism: 80–85%
      - ACTH-secreting pituitary tumor (Cushing disease): ~75%
      - Ectopic ACTH production (e.g., small cell carcinoma of lung, bronchial carcinoid)
    - Endogenous ACTH–independent hypercortisolism: 15–20%
- Adrenal adenoma
- Adrenal carcinoma
- Macronodular or micronodular hyperplasia

- Pediatric/adolescent
  - Adrenal hyperplasia secondary to McCune-Albright syndrome: mean age 1.2 years
  - Adrenocortical tumors: mean age 4.5 years
  - Ectopic ACTH syndrome: mean age 10.1 years
  - Primary pigmented nodular adrenocortical disease: mean age 13.0 years
  - Cushing disease: mean age 14.1 years

- Pregnancy
  - Pituitary-dependent Cushing syndrome
  - Adrenal causes
  - ACTH-independent adrenal hyperplasia

**Genetics**
- Multiple endocrine neoplasia (MEN)
- Carney complex (an inherited multiple neoplasia syndrome)
- McCune-Albright syndrome (mutation of GNAS1 gene)
- Familial isolated pituitary adenomas (mutations in the aryl hydrocarbon receptor–interacting protein gene)
- Activating somatic mutations of the USP8 (ubiquitin-specific protease 8) gene are found in a large proportion of Cushing disease cases. Presence of USP8 mutation in pituitary tumors is linked to higher incidence of tumor recurrence after transsphenoidal surgery.

**RISK FACTORS**
- Preponderance in women: female/male: 3–8/1 for Cushing disease, 4–5/1 for adrenal causes
- Prolonged use of corticosteroids

**GENERAL PREVENTION**
Avoid corticosteroid exposure, when possible.

**COMMONLY ASSOCIATED CONDITIONS**
Psychiatric disorders, diabetes, HTN, hypokalemia, infections, dyslipidemia, osteoporosis, and poor physical fitness

**DIAGNOSIS**

**HISTORY**
- Weight gain: 95%
- Decreased libido: 90%
- Menstrual irregularity: 80%
- Depression/emotional lability: 50–80%
- Easy bruising: 95%
- Diabetes or glucose intolerance: 90%

**PHYSICAL EXAM**
- Obesity (usually central): 95%
- Facial plethora: 90%
- Moon face (facial adiposity): 90%
- Thin skin: 85%
- HTN: 75%
- Hirsutism: 75%
- Proximal muscle weakness: 90%
- Purple striae on the skin
- Increased adipose tissue in neck and trunk, supraclavicular fat pads, buffalo hump
- Acne
- Skeletal growth retardation in children (epiphyseal plates remain open): 70–80%

DIFFERENTIAL DIAGNOSIS
- Obesity
- Type 2 diabetes mellitus
- HTN
- Metabolic syndrome X
- Polycystic ovarian disease
- Pseudo-Cushing (e.g., alcoholism, physical stress, severe major depression)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- 2008 Endocrine Society guidelines recommend against widespread testing for Cushing syndrome except with the following:
  - Adrenal incidentaloma
  - Multiple progressive features suggestive of Cushing syndrome (refer to above “History” and “Physical Exam”)
  - Unusual features for their age such as osteoporosis and HTN
  - Abnormal growth and increased weight in children
- Labs
  - Screening tests
    - Important to differentiate Cushing from pseudo-Cushing (e.g., obesity, alcoholism, depression)
    - Most widely used are the late-night salivary cortisol, 24-hour urinary free cortisol, or low-dose dexamethasone suppression testing
      - Late-night salivary cortisol:
        - Obtain at least two measurements.
        - Cortisol secretion is highest in the morning and lowest between 11 pm and midnight. The nadir of serum cortisol is maintained in pseudo-Cushing but not in Cushing syndrome. Sensitivity and specificity are >90–95%.
      - 24-hour urinary free cortisol level (UFC):
        - Obtain at least two measurements to rule out intermittent hypercortisolism.
        - Also measure 24-hour urinary creatinine excretion to verify adequacy of collection. Results may be falsely low if glomerular filtration rate <30 mL/min.
        - Overall sensitivity and specificity: 90–97% and 85–99%, respectively.
        - Avoid drinking excessive amounts of water due to risk of false-positive values. False-positive values may be seen also in pseudo-Cushing states.
      - Low-dose dexamethasone suppression testing:
Dexamethasone 1 mg is given between 11 pm and midnight, and fasting plasma cortisol is measured between 8 and 9 am the following morning.

A serum cortisol level <1.8 μg/dL excludes Cushing syndrome, but specificity is limited. The presence of pseudo-Cushing states (depression, obesity, etc.), hepatic or renal disease, or any drug that induces cytochrome P450 enzymes may cause a false result.

- Other available screening tests
  - Awake midnight plasma cortisol: Obtain samples on three consecutive nights. A late-evening serum cortisol >7.5 μg/dL has a sensitivity of 99% and specificity of 100%. Persistently elevated serum cortisol implies Cushing syndrome; nadir of serum cortisol is maintained in obese patients but not in Cushing.
  - Corticotropin-releasing hormone (CRH) after dexamethasone: this test though may not be a reliable method to distinguish pseudo-Cushing from Cushing.

After excluding pseudo-Cushing and physiologic hypercortisolism, a referral to an endocrinologist is warranted since patients will need further testing to establish the cause of Cushing. (Refer to “Follow-Up Tests & Special Considerations” in this chapter.)

- Establishing the cause of Cushing syndrome: once the diagnosis of Cushing syndrome is confirmed, localization is the next step.
  - ACTH levels:
    - Less than 5 pg/ml: ACTH independent Cushing
    - More than 20 pg/ml: ACTH dependent Cushing
  - High-dose (8 mg) dexamethasone suppression test: 8 mg of oral dexamethasone is given at 11 pm, with measurement of an 8-am cortisol level the next day.
    - A baseline 8-am cortisol measurement is also obtained the morning prior to ingesting dexamethasone. Suppression of serum cortisol level to <50% of baseline is suggestive of a pituitary source of ACTH rather than ectopic ACTH or primary adrenal disease. Sensitivity and specificity are 95% and 100%, respectively.
    - Another approach is to measure 8-am cortisol after 8 mg dexamethasone given the night before: most Cushing disease patients suppress their cortisol to less than 5 mcg/dl.
  - Other tests include: CRH stimulation and vasopressin stimulation tests

Diagnosis of Cushing syndrome is complicated by the nonspecificity and high prevalence of clinical symptoms in patients without the disorder and involves a variety of tests of variable sensitivity and specificity. Efficient screening and confirmatory procedures are essential before considering therapy.

- Factitious Cushing syndrome is extremely rare (<1% of patients with Cushing syndrome), but should be considered in setting of incongruous hormonal lab results with normal adrenal findings on imaging.

- Imaging
  - Biochemical confirmation of Cushing should be established before obtaining imaging studies due to the possibility of both pituitary and adrenal incidentalomas.
    - Pituitary MRI scan if pituitary tumor is suspected
    - Abdominal CT scan if adrenal disease is suspected
    - Chest CT scan if ectopic ACTH secretion is suspected
    - Octreotide scintigraphy to look for occult ACTH-secreting tumor
    - Up to 19% of ectopic ACTH-secreting tumors can remain occult despite conventional
body imaging and modalities of nuclear imaging such as scintigraphy/SPECT. Dotate PET/CT, a high resolution diagnostic tool that is gaining ground for detecting ectopic ACTH secreting tumors, may be useful in identifying tumors missed by other forms of imaging (1)[C].

- Dual energy x-ray absorptiometry for osteoporosis

**ALERT**
- Antiepileptic drugs, progesterone, oral contraceptives (withdraw estrogen-containing drugs 9 weeks before testing or get a 24-hour UFC), rifampin, and spironolactone may cause a false-positive dexamethasone suppression test.
- Pregnancy: UFC is recommended instead of dexamethasone testing in the initial evaluation of pregnant women (and women on birth control pills). Only UFC in the 2nd or 3rd trimester >3 times the upper limit of normal can be taken to indicate Cushing syndrome.
- Epilepsy: best to use measured cortisol from saliva and urine instead of serum cortisol after dexamethasone since some antiepileptic medications may increase the metabolism of dexamethasone. No data to guide length of time needed after withdrawal of such medication to allow dexamethasone metabolism to return to normal; such medication change may not be clinically possible. Getting a concomitant dexamethasone level may be helpful in such instances.

**Diagnostic Procedures/Other**
- Diagnostic procedure depends on clinical judgment.
- Inferior petrosal sinus sampling with CRH stimulation can be considered if ACTH-dependent tumor is suspected but not localized.
- Associated findings
  - Thyroid function suppressed
  - HTN
  - T2DM
  - Dyslipidemia
  - Polycystic ovarian syndrome/hyperandrogenism
  - Oligomenorrhea/hypogonadism
  - Proximal myopathy/cutaneous wasting
  - Neuropsychiatric problems
  - Ipsilateral adrenal gland hyperplasia and contralateral adrenal gland atrophy
  - Hypercoagulable state/venous thromboembolism
  - Osteoporosis
  - Nephrolithiasis
  - Hypokalemia
  - Growth hormone reduced

**TREATMENT**
Treatment is essential to reduce mortality and associated comorbidities.

**MEDICATION**
- Drugs usually not effective for long-term treatment; used in preparation for surgery or as adjunctive after surgery, pituitary radiotherapy
Metyrapone, ketoconazole, and mitotane all lower cortisol by directly inhibiting synthesis and secretion in the adrenal gland. Replacement glucocorticoid therapy is often required.

Etomidate (intravenously) inhibits the adrenal corticosteroid synthesis.

Mifepristone, a potent glucocorticoid receptor antagonist, is Food and Drug Administration-approved to control hyperglycemia in adults with endogenous Cushing syndrome who have type 2 diabetes or glucose intolerance secondary to hypercortisolism that has not responded to (or who are not candidates for) surgery.

Pasireotide, a somatostatin receptor ligand, is approved for the treatment of Cushing disease when surgery is not successful or cannot be performed. It provides continued clinical benefit (sustained control of cortisol levels and clinical manifestations of hypercortisolism, control of tumor size, increased quality of life, etc.) while maintaining a good safety profile. Hyperglycemia is a common and significant adverse side effect.

Cabergoline, a dopamine agonist, and octreotide, a somatostatin analog, showed promise.

Osilodrostat (a CYP11B1 and CYP11B2 inhibitor) is an adrenal-blocking drug that inhibits steroidogenesis. It is comparable to metyrapone, and superior to ketoconazole, in inhibition of cortisol production in human adrenocortical cells.

Recent studies suggest that pituitary tumor–directed agents such as retinoic acid (vitamin A derivative), silibinin (inhibitor of heat shock protein overexpressed in Cushing disease tumors), and roscovitine (cyclin-dependent kinase inhibitor) may be effective in managing Cushing disease. All three drugs are currently undergoing clinical trial.

SURGERY/OTHER PROCEDURES

- Transsphenoidal surgery:
  - Primary treatment for Cushing disease: remission range of 95–90%
  - Resection of the ACTH-producing ectopic tumor
- Adrenal surgery
  - For unilateral adrenal adenomas, laparoscopic surgery is the treatment of choice.
  - For nodular hyperplasia, bilateral adrenalectomy is usually recommended.
  - For patients with Cushing disease, bilateral laparoscopic adrenalectomy can be considered if persistent disease after pituitary surgery and radiotherapy.
- Radiotherapy and stereotactic radiosurgery (SRS) can be used to treat persistent hypercortisolism after transsphenoidal surgery in Cushing disease.
- SRS: can be used as primary treatment without resection in patients with cavernous sinus tumors
- Risk of hypopituitarism with radiation therapy.

ONGOING CARE

PATIENT EDUCATION

Education of patients and family about disease, treatment options, and expectations, as well as education about diet and monitoring daily weight, early treatment of infections, and emotional lability are crucial.

PROGNOSIS

- Guardedly favorable prognosis with surgery for Cushing disease; generally chronic course with cyclic exacerbations and rare remissions
Better prognosis following surgery for benign adrenal tumors; long-term recurrence rate is 20%.

Poor with small cell carcinoma of the lung producing ectopic hormone; neuroendocrine tumors (bronchial carcinoid) have much better prognosis.

After surgery, a drop in cortisol level is a predictor

Some patients may need supraphysiologic dose of steroid replacement postsurgery, which is tapered down and stopped over months to years.

**COMPLICATIONS**

- Osteoporosis
- Increased susceptibility to infections
- Metastases of malignant tumors
- Venous thromboembolism than the general population
- Increased cardiovascular risk even after treatment
- Lifelong glucocorticoid dependence following treatment with bilateral adrenalectomy
- Nelson syndrome after treatment with bilateral adrenalectomy (can occur in 8–38% of patients)
- Depression, body image disturbances, and poor emotional quality of life

**REFERENCES**

**SEE ALSO**

Algorithm: Cushing Syndrome

**CODES**

**ICD10**

- E24.9 Cushing’s syndrome, unspecified
- E24.0 Pituitary-dependent Cushing’s disease
- E24.2 Drug-induced Cushing’s syndrome

**CLINICAL PEARLS**

- Cushing disease is due to excessive ACTH secretion from a pituitary tumor, resulting in corticosteroid excess.
- Cushing syndrome is due to excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor.
- Depression, alcoholism, medications, eating disorders, and other conditions can cause mild clinical and laboratory findings similar to those in Cushing syndrome (pseudo-Cushing syndrome).
- Diagnosis can be challenging.
CUTANEOUS DRUG REACTIONS
David H. Yun, MD ● Jonathan M. Novotney, DO ● Sicong Wang, MD

BASICS

DESCRIPTION
- An adverse cutaneous reaction in response to administration of a drug. Rashes are the most common form of adverse drug reaction (ADR).
- Severity can range from mild eruptions that resolve within 24 hours after the removal of the inciting agent, to severe skin damage with multiorgan involvement.
- Morbilliform and urticarial eruptions are the most common, accounting for approximately 94% of cutaneous drug reactions.
- Approximately 2% are severe and life-threatening.

EPIDEMIOLOGY
- All ages affected
- Immunosuppressed individuals at increased risk
- Patients with AIDS are 8.7 times more likely to develop cutaneous drug reactions compared to general population.
- Increased likelihood of severe cutaneous and systemic reactions in geriatric population; unclear if due to polypharmacy or change in drug metabolism
- Difficult to distinguish from viral exanthems in pediatric patients

Incidence
In the United States, incidence of 1–3% in hospitalized patients; estimated 1/1,000 hospitalized patients has had a severe cutaneous reaction.

ETIOLOGY AND PATHOPHYSIOLOGY
Two classifications of ADR:
- Predictable (type A): dose dependent, known pharmacologic effect of drug, and drug–drug interaction
- Unpredictable (type B): drug intolerance, drug idiosyncrasy secondary to abnormality in metabolism, drug allergy, and drug pseudoallergy
- Immunologically mediated reaction: immunoglobulin (Ig) E–mediated reaction (type I hypersensitivity), cytotoxic/IgG/IgM induced (type II), immune complex reactions (type III), and delayed-type hypersensitivity (type IV) with T cells, eosinophils, neutrophils, and monocytes
- >700 drugs are known to cause cutaneous drug reactions.
  - Morbilliform/urticarial/exfoliative erythroderma: penicillins, cephalosporins, sulfonamides, tetracyclines, ibuprofen, naproxen, allopurinol, acetylsalicylic acid, radiocontrast media
  - Acneiform: OCPs, corticosteroids, iodinated compounds, hydantoins, lithium
  - Fixed drug eruptions: NSAIDs, sulfonamides, tetracycline, barbiturates, salicylates, OCPs
  - Acute generalized exanthematous pustulosis (AGEP): penicillins, cephalosporins, macrolides, calcium channel blockers, antimalarials, carbamazepine, acetaminophen, terbinafine, nystatin, vancomycin
  - Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome: anticonvulsants,
sulfonamides, dapsone, minocycline, allopurinol

– Erythema multiforme/Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN): >100 drugs reported. Most common include sulfonamides, cephalosporins, NSAIDs, barbiturates, hydantoins, anticonvulsants tetracycline, terbinafine, allopurinol.

– Lichenoid: thiazides, NSAIDs, gold, ACE inhibitors, proton pump inhibitors, antimalarials, sildenafil

– Photosensitivity: doxycycline, thiazides, sulfonylureas, quinolones, sulfonamides, NSAIDs

– Hyper-sensitivity vasculitis: hydralazine, penicillins, cephalosporins, thiazides, gold, sulfonamides, NSAIDs, propylthiouracil

– Sweet syndrome (acute febrile neutrophilic dermatosis): sulfa drugs, granulocyte colony-stimulating factor (G-CSF), granulocyte-macrophage colony-stimulating factor (GM-CSF), diazepam, minocycline, nitrofurantoin, captopril, penicillamine

**Genetics**

Genetics may play a role because certain HLA antigens have been associated with increased predisposition to specific drug eruptions:

- HLA-B*5801, HLA-B*5701, and HLA-B*1502 have been linked to allopurinol-induced and carbamazepine-induced SJS/TEN, respectively.
- HLA-DQB1*0301 allele found in 66% of patients of erythema multiforme compared with 31% of control subjects
- HLA class I antigens, such as HLA-A2, HLA-B12, and HLA-B22, have been linked to TEN and fixed drug eruptions, respectively.
- CYP2C9*3 variants linked to phenytoin-induced SJS/TEN

**RISK FACTORS**

Previous drug reaction, polypharmacy, concurrent infection, immunocompromised, disorders of metabolism, and certain genetic HLA haplotypes

**GENERAL PREVENTION**

Always ask patients about prior adverse drug events. Be aware of medications with higher incidence of reactions as well as drug–drug reaction.

**DIAGNOSIS**

**HISTORY**

- Any new medication within the preceding 6 weeks (oral, parenteral, and topical agents, including over-the-counter drugs, vitamins, and herbal remedies)
- Consider other etiologies: unrelated acute or chronic urticaria, bacterial infections, viral exanthems, or underlying skin disease including cutaneous lymphoma.

**PHYSICAL EXAM**

May present as a number of different eruption types, including, but not limited to the following:

- Morbilliform eruptions (exanthems)
  - Most frequent cutaneous reaction (75–95%); difficult to distinguish from viral exanthem; often secondary to an antibiotic
  - Starts on trunk as pruritic red macules and papules, then extends symmetrically to extremities in confluent fashion, sparing face, palms, soles, and mucous membranes
- Onset usually 7 to 21 days after drug initiation (2)

Urticaria
- Pruritic erythematous wheals distributed anywhere on the body, including mucous membranes
- Lesions can vary in size and shape (e.g., round oval, rhomboid) and may change over time.
- Angioedema, a related manifestation, may appear as asymmetric soft tissue swelling which can compromise airway and be life-threatening.
- Individual lesions usually fade within 24 hours, but new lesions may develop.

Acneiform eruptions
- Folliculocentric, monomorphous pustules typically involving the face, trunk, and proximal extremities, can also present in areas atypical of acne vulgaris such as forearms and legs.
- Distinguished from acne vulgaris by absence of comedones

Fixed drug eruptions
- Solitary/few, sharply demarcated, round and/or oval erythematous plaques with dusky center that may leave postinflammatory hyperpigmentation; occur on skin or on mucous membrane
- Appear shortly after drug exposure and recur in identical location after reexposure; some patients have a refractory period during which the drug fails to activate lesions.
- Onset usually 30 minutes to 8 hours after administration of drug

AGEP
- Rapidly appearing multiple nonfollicular sterile pustules on erythematous background typically involving intertriginous areas
- Usually resolves within 1 to 3 days after removal of offending drug leaving a desquamation pattern
- AGEP often causes fever and marked leukocytosis with neutrophilia and/or eosinophilia.

DRESS syndrome
- Drug-induced, multiorgan inflammatory response which may be life-threatening
- Presentation can involve cutaneous eruptions (typically pruritic erythematous papules and patchy erythematous macules), fever, eosinophilia (most cases but not all), hepatic dysfunction, renal dysfunction, and lymphadenopathy.
- Onset usually 2 to 8 weeks after drug exposure
- Symptoms and organ involvement may worsen after discontinuation of offending agent and persist for months.
- Mucosal involvement rare (3)

Erythema multiforme
- Acute, immune-mediated, mucocutaneous condition
- Most commonly associated with herpes simplex virus (HSV) and other viral/bacterial etiologies (i.e., Mycoplasma); less likely secondary to drug exposure (<10% of cases)
- Palpable classic target lesions and/or two-zone atypical target lesions with localized erythema
- Most commonly distributed symmetrically on extensor surfaces of acral extremities; may involve mucus membrane (25–60%)

SJS/TEN
- Classification and distinction between SJS and TEN determined by affected body surface area (BSA)
  - SJS: <10% BSA; SJS–TEN overlap: 10–30% BSA; TEN: >30% BSA
- TEN strongly associated with drug intake (>95%); SJS less strongly associated (~50%)
- Onset is usually 4 to 28 days but as delayed as 8 weeks after starting offending drug: flat atypical two-zone target lesions and erythematous macules that are truncal and generalized with mucosal involvement
- May develop confluent areas of bullae, erosions, and necrosis; significant risk for infection and sepsis
- SJS: 1–5% mortality; TEN: 25–35% mortality

- **Lichenoid eruptions**
  - Eruption of violaceous, pruritic polygonal papules symmetrically distributed favoring extensor surfaces/sun-exposed areas
  - Time frame of onset varies depending on causative medication.
  - Chronic lesions persist for weeks/months after the drug discontinued.

- **Photosensitivity reaction**
  - Phototoxict reactions: usually occur within minutes to hours after sunlight exposure with exaggerated sunburn reaction
  - Photoallergic reactions: more pruritic than painful; photodistributed sparing scalp, submental, and periorbital areas

- **Hypersensitivity vasculitis**
  - Nonblanching petechiae/palpable purpura which commonly present on lower extremities
  - Onset usually 7 to 21 days after drug exposure
  - Biopsy shows inflammation and necrosis of vessel walls.
  - Renal, hepatic, pulmonary, GI, and CNS involvement possible but uncommon

- **Sweet syndrome**
  - Fever; neutrophilia; tender, edematous violaceous papules; plaques; or nodules, with or without pustules/vesicles that spontaneously resolve
  - Classically seen in young women after a mild respiratory illness or GI infection

- **Exfoliative dermatitis/erythroderma**
  - Severe end-stage dermatosis that develops from other drug reactions; commonly associated with systemic manifestations such as fever and chills
  - Generalized erythema with exfoliation and/or fine desquamation of large confluent areas
  - Increased risk of secondary infection and insensible fluid and temperature loss with hemodynamic instability

**DIFFERENTIAL DIAGNOSIS**

- **Viral exanthem:** Presence of fever, lymphocytosis, and other systemic findings may help in narrowing differential.

- **Primary dermatosis (e.g., pustular psoriasis):** Correlation of drug withdrawal to rash resolution may clarify diagnosis; skin biopsy is helpful.

- **Bacterial infection:** Cultures of pustules may distinguish primary infection from AGEP and acneiform eruptions.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Selection of initial tests should be guided by clinical history and physical exam findings. CBC with differential; significant eosinophilia may be seen in DRESS and other drug-induced allergic reactions. LFT, urinalysis, and serum creatinine to assess for internal organ involvement; chest x-ray if suspected vasculitis.
Diagnostic Procedures/Other
- Special tests depend on suspected mechanism:
  - Type I: skin/intradermal testing, radioallergosorbent test (RAST)
  - Type II: direct/indirect Coombs test
  - Type III: ESR, C-reactive protein, ANA, complement components, cryoglobulin assays
  - Type IV: patch testing, lymphocyte proliferation assay (investigational)
  - Anaphylaxis/nonimmunologic mast and basophil cell reaction: plasma histamine, serum tryptase levels, 24-hour urine N-methylhistamine
- Cultures useful in excluding infectious etiology; skin biopsy is nonspecific but useful in characterizing an eruption and excluding primary skin pathologies.
- Develop a timeline documenting the onset and duration of all drugs, dosages, and onset of cutaneous eruption (1)[A].

Test Interpretation
- Nonspecific histologic findings are superficial epidermal and dermal infiltrates composed variably of lymphocytes, neutrophils, and eosinophils.
- SJS/TEN: partial or full-thickness necrosis of the epidermis necrotic keratinocytes, vacuolization leading to subepidermal blister at basal membrane zone

TREATMENT

GENERAL MEASURES
- Do not rechallenge with drugs causing urticaria, bullae, angioedema, DRESS, anaphylaxis, or erythema multiforme.

MEDICATION
- Immediate withdrawal of offending drug. Depending on the type of eruption, symptomatic treatment may be useful, but most require no additional therapy except cessation of offending agent.
- Anaphylaxis or widespread urticaria: epinephrine 0.1 to 0.5 mg (1:1,000 [1 mg/mL] solution) IM in the mid-outer thigh every 5 to 15 min; prednisone PO 1 mg/kg in tapering doses may be given for severe refractory cases.
- Acute urticaria (<6 weeks) and chronic urticaria (>6 weeks): 2nd-generation antihistamines (preferred, less sedating): cetirizine 10 to 20 mg daily, loratadine 10 to 20 mg daily, fexofenadine 180 mg daily. H₂ antagonists: ranitidine 150 mg BID
- Erythema multiforme
  - Treatment is generally supportive with management of suspected underlying infection.
  - Recurrent, HSV associated: prophylaxis with acyclovir 400 mg BID, valacyclovir 500 mg BID, or famciclovir 250 mg BID (4)[C]
  - “Magic mouthwash” and oral antiseptic helpful for mucosal erosions. Consider ophthalmology consult for severe ocular involvement (4)[C].
- SJS/TEN: Treatment is supportive. Consult with a dermatologist, ophthalmologist, and gynecologist as applicable. Systemic corticosteroid use remains controversial. Consider IVIG
2 to 3 g/kg for severe disease, although limited studies have not shown survival benefits in adults. In pediatric SJS/TEN patients, IVIG and systemic glucocorticoids appear to improve outcome; varied success rates reported with use of antitumor necrosis factor-α agents, cyclosporine, cyclophosphamide, and plasmapheresis. Avoid débridement and consider using detached epidermis as natural biologic dressing to minimize risk for hypertrophic scars (5)[C].

- DRESS: prompt removal of offending drug and supportive measures; high-potency topical steroids for rash; systemic steroids with severe organ involvement; appropriate supportive multidisciplinary care guided by organ involvement (6)[C]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- For urticarial, bullous, DRESS, or erythema multiforme spectrum lesions, close follow-up is needed; may even require hospitalization if suspicious for life-threatening type including SJS/TEN and DRESS
- Patients with anaphylaxis/angioedema should be given EpiPens to be kept at home, work, and in the car for secondary prevention and a Med-Alert bracelet; label the patient’s medical record with the agent and reaction.
- If the patient needs to take the inciting drug (e.g., antibiotic) in the future, induction of drug tolerance or graded challenge procedures may be necessary.

**PROGNOSIS**
- Majority of cases are self-limiting upon removal of offending drug.
- Eruptions generally begin fading within days after removing offending agent. With morbilliform eruptions, eruption may spread distally even when agent is removed, resolving over time.
- Anaphylaxis, angioedema, DRESS, SJS/TEN, and bullous reactions are potentially fatal.
- Severity-of-illness score for toxic epidermal necrolysis (SCORTEN), a prognostic scoring system, can be used to guide management of hospitalized patients of SJS/TEN; also, may be helpful when discussing prognosis

**COMPLICATIONS**
Anaphylaxis, bone marrow suppression, hepatitis (dapsone, hydantoin), renal failure, psychological trauma, sepsis, and pulmonary and thyroid toxicity

**REFERENCES**

CODES

ICD10

- L27.1 Loc skin eruption due to drugs and meds taken internally
- L50.0 Allergic urticaria
- R21 Rash and other nonspecific skin eruption

CLINICAL PEARLS

- Virtually, any drug can cause a rash; antibiotics are the most common culprits that cause cutaneous drug reactions.
- Focus on drug history with new suspicious skin eruptions.
- Usually self-limited after withdrawal of offending agent
- Symptoms such as tongue swelling/angioedema, skin necrosis, blisters, high fever, dyspnea, and mucous membrane erosions signify more severe drug reactions.
- Useful resources: Drug Eruption Reference Manual by Jerome Litt; www.drugeruptiondata.com
CYCLIC VOMITING SYNDROME
Jennifer M. Cornwell, DO

BASICS

DESCRIPTION
- An idiopathic chronic functional GI disorder characterized by discrete, recurrent, stereotypical paroxysmal episodes of high-intensity nausea and vomiting lasting hours to days, separated by symptom-free intervals
- Subsets
  - Cyclic vomiting syndrome (CVS) plus two or more neuromuscular disorders in association
  - Catamenial CVS: associated with menstrual cycle
- CVS has four distinct phases:
  - Interepisodic: symptom-free period
  - Prodromal: often marked by nausea with or without abdominal pain; able to take oral medications; minutes to hours
  - Vomiting: nausea, vomiting, and retching
  - Recovery: Nausea remits and patient recovers appetite, strength, and energy (1)[B].

EPIDEMIOLOGY

Prevalence
- 0.04–2% in general population
- Whites affected more than other races
- Predominant sex: female > male (55:45)
- More common in children; mean age of diagnosis is 5 years in children and 35 years in adults.
- Average of 3 years from symptom onset to diagnosis

ETIOLOGY AND PATHOPHYSIOLOGY

- Strong link between CVS and migraine, with similar symptoms, frequent family history of migraines, and effectiveness of antimigraine therapy
- Unknown etiology. One proposed mechanism:
  - Heightened neuronal excitability owing to enhanced ion permeability, mitochondrial deficits, or hormonal state → increased susceptibility to physical or psychological trigger → release of corticotropin-releasing factor (CRF) → vomiting
  - Vomiting perpetuated by altered brainstem regulation → sustained vomiting
- Possible maternal inheritance, based on family history of migraines and link to mitochondrial DNA (mtDNA) mutations (2)[B]
- Multiple theories:
  - GI motility dysfunction
  - Autonomic dysfunction: sympathetic (1)[B]
  - Food allergy or intolerance

Genetics
- Likely matrilineal inheritance, especially with childhood onset
- A3243G or other mtDNA mutations including mitochondrial dysfunction (2)[B]
Ion channel mutations
Several polymorphisms have been identified. 165119T more common in children with CVS.

RISK FACTORS
- Family history of migraine headaches
- Depression and/or anxiety
- Chronic cannabis use
- Possibly food allergies or hypothalamic-pituitary-adrenal axis dysfunction

COMMONLY ASSOCIATED CONDITIONS
- Irritable bowel syndrome (67%)
- Headaches (52%)
- Motion sickness (46%)
- Migraines (11–40%)
- Seizure disorder (5.6%)
- Cannabis use

DIAGNOSIS

HISTORY
- Children often present with bilious emesis (83%), severe abdominal pain (80%), and/or hematemesis.
- The North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition consensus criteria for diagnosing CVS:
  - At least five attacks in any interval or a minimum of three attacks during a 6-month period
  - Episodic attacks of intense nausea and vomiting lasting 1 hour to 10 days and occurring at least 1 week apart
  - Stereotypical pattern and symptoms
  - Vomiting at least 4 times per hour for at least 1 hour during attack
  - Return to baseline between episodes
  - Not attributable to another disorder
- Rome III criteria for adults
  - Stereotypical onset (acute) and duration (<1 week) of vomiting episodes
  - ≥3 discrete episodes in the prior year
  - Absence of nausea and vomiting between episodes
  - Supporting criterion: history or family history of migraine headaches
- Adult hallmarks
  - Prominence of epigastric or diffuse abdominal pain
  - Increased prevalence of anxiety and depression
  - Normal or rapid gastric emptying
  - Successful suppression of attacks by chronic amitriptyline therapy (1)[B]

PHYSICAL EXAM
Evaluate for dehydration (seen in 30%).
- Orthostatic hypotension
- Tachycardia
- Decreased skin turgor
Dry mucous membranes
General physical exam often otherwise normal

DIFFERENTIAL DIAGNOSIS
- GI disorders: GERD; Helicobacter pylori, cholelithiasis, pancreatitis, obstruction, gastroparesis
- Neurologic disorders: migraine headaches, Chiari malformation, intracranial mass
- Renal disorders: nephrolithiasis, obstruction
- Metabolic and endocrine disorders: porphyria, Addison disease, diabetic ketoacidosis, hyperemesis gravidarum, pheochromocytoma
- Behavioral disorders: Münchausen by proxy, anxiety, bulimia nervosa, depression
- Pregnancy
- Cannabinoid abuse—cannabis hyperemesis syndrome (CHS): Symptoms include episodic nausea, vomiting, abdominal pain, and compulsive bathing with hot water (3)[B].

Any child with suspected CVS should be evaluated for a possible metabolic or neurologic etiology if:
- Child is <2 years of age.
- Vomiting episodes are associated with concurrent illnesses, prior fasting, or increased protein intake.
- Any focal findings on neurologic exam
- Hypoglycemia, anion gap metabolic acidosis, hyperammonemia, or other findings suggestive of metabolic disorders

DIAGNOSTIC TESTS & INTERPRETATION
CVS is a diagnosis of exclusion (2)[B]. Tests help rule out other diagnoses and exclude complications.

Initial Tests (lab, imaging)
- Electrolytes: hypokalemia (Addison disease exhibits hyponatremia and hypoglycemia.)
- CBC: hemoconcentration and leukocytosis
- Amylase and lipase (pancreatitis)
- ESR
- Hepatic transaminases (hepatitis or gallbladder disease)
- Urinalysis: granular casts, ketones
- Urine drug screen: THC (False positives can occur, especially after IV PPI administration.) (3)[B]
- Pregnancy test
- Lactate, ammonia, amino acids, urine organic acids, adrenocorticotropic hormone—particularly for acute episodes in children to exclude metabolic disease
- Upper GI series to exclude malrotation
- Abdominal US to exclude transient hydronephrosis, gallstones, and ureteropelvic junction obstruction
- Esophagastroduodenoscopy (EGD) if active hematemesis is present

Follow-Up Tests & Special Considerations
- Counseling—behavioral health for management of anxiety, depression, eating disorders, or cannabis abuse (if applicable)
- CT or MRI of head—assess for structural lesions of the brain or causes of increased ICP.
- CT of the abdomen and pelvis—evaluate biliary and urinary tracts to exclude structural causes.
Diagnostic Procedures/Other
- EGD: to evaluate for clinical suspicion of peptic ulcer disease or signs of hematemesis
- Electroencephalogram: seizure disorder evaluation
- Gastric emptying studies: Exclude gastroparesis (1)[B].
- Autonomic testing
- Neuropsychiatric testing

TREATMENT

GENERAL MEASURES
- Patient reassurance
- Avoid triggers (stress, sleep deprivation, chocolate, cheese, monosodium glutamate, red wine) (4)[A].
- Nonstimulating environment
- Relaxation techniques and psychological testing
- Avoid recreational drugs (marijuana).

MEDICATION

First Line
- Lifestyle modification for episode prevention:
  - Drink sufficient fluids, eat regularly without skipping meals, exercise regularly (5)[B].
  - Avoid sleep deprivation, triggering foods, and motion sickness to reduce episode frequency.
- Consider prophylactic pharmacotherapy if an affected child is having repeated episodes requiring frequent hospitalization or school absences.
  - Prophylactic medications (decrease frequency or severity by >50%)
  - Many prophylactic medications for CVS are pregnancy risk Category C or greater risk. Therefore, discussion of risk versus benefit of treatment during pregnancy should be discussed with these patients.
    - Amitriptyline (67–82%): children >5 years: 0.2 to 2.0 mg/kg/day not recommended for children <5 years; slow titration over 2 to 3 weeks to avoid side effects
    - Cypheptadine (39–66%): children 2 to 5 years: 0.25 to 0.50 mg/kg/day divided BID–TID; appetite stimulant; usually first-line treatment for children <5 years; especially if associated with migraines (4)[A]
    - Propranolol (57%): children: 0.5 mg/kg/day divided BID–TID; adults: 10 to 20 mg/day BID to TID especially if associated with migraines (4)[A]
  - Adjuncts
    - Antiemetics, anticonvulsants, mitochondrial supplements, tricyclic antidepressants, calcium channel blockers (5)[B]
    - Topiramate: adults with CVS and chronic headaches; 20 to 100 mg daily (4)[A]; 2 mg/kg/day divided BID (5)[B]
    - Ondansetron: children: 0.3 to 0.4 mg/kg/dose (<16mg) q6h; adults: 4 mg IV/PO q6–8h
    - Lorazepam: children: 0.05 to 0.10 mg/kg/dose IV (not to exceed 4 mg/dose); adults: 1 mg PO QID to reduce anxiety (4)[A]
    - Sumatriptan: (patient >40 kg) 20 mg intranasal PRN

Second Line
● Prophylactic
  – Phenobarbital (79%): 2 to 3 mg/kg/day
  – Erythromycin (75%): 20 mg/kg/day divided BID–TID
  – Valproic acid: 10 to 40 mg/kg/day (avoid if possible and substitute adjunctive mitochondrial supplements) (5)[B]
  – Levetiracetam: 500 to 3,000 mg daily adults (4)[A]
  – Zonisamide: 100 to 700 mg daily adults (4)[A]
  – Pizotifen: 0.25 mg BID–TID (5)[B]
  – Flunarizine: 5 mg once a day (5)[B]
  – Mirtazapine: 7.5–15 mg once at night (5)[B]
  – Aprepitant: twice weekly—<40 kg = 40 mg; 40–60 kg = 80 mg; >60 kg = 125 mg (5)[B]
  – Erythromycin: 20 mg/kg/day divided 4 times in a day (5)[B]

● Supportive
  – Seek to use IV rectal or dermal medications to decrease repeated vomiting (5)[B]
  – Diphenhydramine: children: 1.25 mg/kg/dose q6h, not to exceed 300 mg/day; adults: 25 to 50 mg q4–6h PRN
  – Aprepitant: 30 min before vomiting, day 2 and 3 –if <15 kg = 80 mg/40 mg/40 mg; if 15–20 kg = 80 mg/80 mg/80 mg; if >20 kg = 125 mg/80 mg/80 mg (5)[B]
  – Metoclopramide: 0.1 mg/kg/dose q6hr (5)[B]
  – Chlorpromazine + diphenhydramine: 0.5–1.0mg/kg q8hr (5)[B]
  – Ketoralac: 0.5–1.0 mg/kg/dose <10 mg q8hr (5)[B]
  – Hydromorphone: children: 0.015 mg/kg/dose IV for 1 dose; adults: 2 to 4 mg PO PRN or 0.5 to 2.0 mg IM/SC for 1 dose

● Rescue therapy
  Fluids, adequate caloric intake, antiemetics, sedative medications (5)[B]; most episodes (72%) end with premonitory sleep and therefore induced sleep can cause symptomatic relief and may shorten an episode (5)[B]

**ISSUES FOR REFERRAL**
Regular behavioral health appointments and consultation with a supportive gastroenterologist can decrease episodes of CVS and reduce inappropriate pharmacotherapy.

**ADDITIONAL THERAPIES**
Relaxation techniques:
● Deep breathing
● Biofeedback
● Guided imagery

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
● Coenzyme Q10 10 mg/kg/day divided BID for prevention (5)[B] up to 300 mg daily (4)[A]
● L-carnitine 50–100 mg/kg/day divided BID for prevention (5)[B] up to 3 g daily (4)[A]
● Riboflavin 10 mg/kg/day divided BID for prevention (5)[B]
● While marijuana is a potential treatment for intractable vomiting, regular use may cause cannabinoid hyperemesis syndrome (CHS) (3)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
● Admission criteria/initial stabilization
  – Dehydration requiring >2 L of IV fluids
– Failure of outpatient management
– Increased anion gap that reflects severe dehydration or metabolic decompensation
– IV fluids or IV medications
– Lorazepam 1 to 2 mg IV q3h main approach to induce sleep most effective in acute crisis

IV fluids: replacement of ongoing losses; 5–10% dextrose-containing fluids or normal saline with added potassium to attenuate any metabolic crisis

Nursing
– Decrease stimulation; avoid noise and bright light.
– Supportive care
– Encourage relaxation techniques.
– Avoid unnecessary interruptions during sleep.

Discharge criteria
– Vomiting and electrolyte imbalances resolved
– Pain managed with oral analgesia
– Euvolemia
– Appropriate oral intake

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
– Weekly appointments for severe cases
– Monitor for hypokalemia, acid-base disturbances, and ketosis if ongoing emesis.
– Regular outpatient visits for support

DIET
– Foods rich in carbohydrates, vitamins, and minerals
– A low-amine diet may help in children.
– Limit fats and spicy foods.
– Avoid trigger foods: chocolate, cheese, and monosodium glutamate.
– Consistent meal schedules
– Maintain good hydration.

PATIENT EDUCATION
– A vomiting diary identifies potential triggers in 75% of children.
– Stress management
– Sleep hygiene
– Regular, moderate exercise
– Cyclic Vomiting Syndrome Association Web site: www.cvsaonline.org

PROGNOSIS
– Usually lasts 2.5 to 5.5 years
– Vomiting resolves in 70% of children. Many continue to have somatic symptoms (headache; abdominal pain).
– 35% develop recurrent/migraine headaches.
– 50–75% of patients treated prophylactically are asymptomatic at 1 year.
13% are nonresponsive to therapy. Risk factors for nonresponse include poorly controlled migraines, psychiatric conditions, chronic narcotic use, and marijuana use (4).[A].

COMPlications
Occur during vomiting phase:
- Dehydration and hypovolemic shock
- Electrolyte derangement, including the syndrome of inappropriate antidiuretic hormone
- Hematemesis
- Peptic esophagitis
- Mallory-Weiss tear
- Weight loss

REFERENCES

ADDITIONAL READING

CODES
ICD10
- G43.A0 Cyclical vomiting, not intractable
- G43.A1 Cyclical vomiting, intractable
CLINICAL PEARLS

- CVS is more common in children than adults. The average age of diagnosis is 5 years.
- A food diary helps identify patterns and triggers for vomiting cycles.
- Proper sleep hygiene, stress management, and appropriate diet help mitigate symptoms.
- Treatment in the vomiting phase often requires a combination of pharmacologic and psychosocial interventions.
- Long-term prophylaxis can help reduce frequency and duration of recurrent vomiting cycles. Amitriptyline is the drug of choice in patients age >5 years.
BASICS

DESCRIPTION
- Cystic fibrosis (CF) is an autosomal recessive genetic mutation (CFTR gene) that most prominently affects the pulmonary and pancreatic systems. The gastrointestinal (GI), endocrine, and reproductive systems as well as the liver, sinuses, and skin can all be involved.
- Initially a pediatric disease, CF has become a chronic pediatric and adult medical condition as improvements in medical care have led to a dramatic increase in long-term survival, resulting in adults living with the disease outnumbering children in 2014.

EPIDEMIOLOGY
Although CF is the most common lethal inherited disease in Caucasians, it is found in every racial group.

Incidence
Number of infants born with CF in relation to the total number of live births in the United States
- 1 in 3,200 Caucasians
- 1 in 10,000 Latin Americans
- 1 in 10,500 Native Americans
- 1 in 15,000 African Americans
- 1 in 30,000 Asian Americans

Prevalence
More 30,000 patients with CF living in the United States and 70,000 worldwide. The median predicted survival for CF patients in the U.S. was 39.3 years (95% CI, 37.3–41.4).

ETIOLOGY AND PATHOPHYSIOLOGY
- Primary defect is abnormal function of an epithelial chloride channel protein encoded by the CFTR (CF transmembrane conductance regulator) gene on chromosome band 7q31.2. CFTR functions as a regulated chloride channel, which may regulate the activity of other chloride and sodium channels at the cell surface. Abnormal CFTR function leads to abnormally viscous secretions that alter organ functions.
- The lungs: Obstruction, infection, and inflammation negatively affect lung growth, structure, and function.
  - Decreased mucociliary clearance
  - Infection is accompanied by an intense neutrophilic response.
  - Degradation of supporting tissues causes bronchiectasis and eventual failure.

Genetics
CF is a single-gene disorder. CFTR gene has >1,500 mutations that can cause varying severity of phenotypic CF, all of which are recessively inherited. Most common is loss of the phenylalanine residue at 508th position (deltaF508), which accounts for 8.7% of affected alleles in the CF population in the United States. G551D mutation accounts for 4.3% of affected alleles. The
severity of the phenotype can be affected by the specific CFTR mutation (most predictive of pancreatic disease), other modifier genes (CFTM1 for meconium ileus), gastroesophageal reflux disease (GERD), severe respiratory virus infection, and environmental factors such as tobacco smoke exposure.

**GENERAL PREVENTION**

Preconception counseling
- American Congress of Obstetricians and Gynecologists (ACOG) recommends preconception or early (1st/2nd trimester) genetic analysis for all North American couples planning a pregnancy, with appropriate counseling to identified carriers and genetic analysis of siblings of known CF patients.
- Universal newborn screening (NBS) has been integral in early diagnosis (64% of new CF diagnosis in 2014 were found by NBS). Patients diagnosed prior to onset of symptoms have better lung function and nutritional outcomes and should receive referral and early intervention services by an accredited regional CF center.

**COMMONLY ASSOCIATED CONDITIONS**

- CF-related diabetes (CFRD)
  - May present as steady decline in weight, lung function, or increased frequency of exacerbation
  - Leading comorbid complication (20.7%)
  - Result of progressive insulin deficiency
  - Early screening and treatment may improve reduced survival found in CFRD.
- Upper respiratory
  - Rhinosinusitis is seen in up to 100% of patients with CF.
  - Nasal polyps are seen in up to 86% of patients.
- The GI tract
  - Pancreatic exocrine insufficiency (85–90%)
  - Malabsorption of fat, protein, and fat-soluble vitamins (A, D, E, and K)
  - Hepatobiliary disease (12.6%)
  - Focal biliary cirrhosis
  - Cholelithiasis
  - Meconium ileus at birth (10–15%)
  - Distal intestinal obstruction syndrome (DIOS): intestinal blockage that typically occurs in older children and adults (5.3%)
  - GERD (32.7%)
- Endocrine
  - Bone mineral disease (16.6%)
  - Joint disease (3.0%)
  - Hypogonadism
  - Frequent low testosterone levels in men
  - Menstrual irregularities are common.
- Reproductive organs
  - Congenital bilateral absence of the vas deferens: obstructive azoospermia in 98% of males
- Depression (12.8%)

**Pregnancy Considerations**
Pulmonary disease may worsen during pregnancy.

CF may cause increased incidence of preterm delivery, IUGR, and cesarean section.

Advances in fertility treatments now allow men with CF to father children.

DIAGNOSIS

Criteria for diagnosis of cystic fibrosis (1)[A]

- At least one of the following:
  - One or more typical phenotypic features of CF:
    - Chronic pulmonary disease
    - Chronic sinusitis
    - Characteristic gastrointestinal and nutritional abnormalities
    - Salt loss syndromes
    - Obstructive azoospermia
  - History of cystic fibrosis in a sibling
  - Positive newborn screening test
- PLUS at least one:
  - Elevated sweat chloride concentration on two or more occasions
  - Two mutations known to cause CP on separate alleles
  - Abnormalities in nasal potential difference (NPD) testing that are typical of CF

HISTORY

- Routine prenatal ultrasonography indicates hyperechogenic bowel.
  - The risk is highest if there is evidence of meconium peritonitis (scattered calcifications are seen throughout the fetal peritoneum), bowel dilatation, or absent gallbladder. Parents should be offered prenatal CF carrier screening if any of these findings are present.
- Suspect with failure to thrive, steatorrhea, and recurrent respiratory problems.
  - Chronic/recurrent respiratory symptoms, including airway obstruction and infections
  - Persistent infiltrates on chest x-rays (CXRs)
  - Hypochloremic metabolic acidosis
- History during neonatal period
  - Meconium ileus (20%) (generally considered pathognomonic for CF)
  - Prolonged jaundice
- History during infancy
  - Failure to thrive
  - Chronic diarrhea
  - Anasarca/hypoproteinemia
  - Pseudotumor cerebri (vitamin A deficiency)
  - Hemolytic anemia (vitamin E deficiency)
- History during childhood
  - Recurrent endobronchial infection
  - Bronchiectasis
  - Chronic pansinusitis
  - Steatorrhea
  - Poor growth
  - DIOS
- Allergic bronchopulmonary aspergillosis (ABPA)
- History for adolescence and adulthood (7% diagnosed >18 years old)
  - Recurrent endobronchial infection
  - Bronchiectasis
  - ABPA
  - Chronic sinusitis
  - Hemoptysis
  - Pancreatitis
  - Portal hypertension
  - Azoospermia
  - Delayed puberty

**PHYSICAL EXAM**

- Respiratory
  - Rhonchi and/or crackles
  - Hyperresonance on percussion
  - Nasal polyps
- GI: hepatosplenomegaly when cirrhosis present
- Other: digital clubbing, growth retardation, and pubertal delay

**DIFFERENTIAL DIAGNOSIS**

- Immunologic
  - Severe combined immunodeficiency
- Pulmonary
  - Difficult-to-manage asthma
  - Chronic obstructive pulmonary disease
  - Recurrent pneumonia
  - Chronic/recurrent sinusitis
  - Primary ciliary dyskinesia
- GI
  - Celiac disease
  - Protein-losing enteropathy
  - Pancreatitis of unknown etiology
  - Shwachman-Diamond syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Newborn Screening tests blood levels of immunoreactive trypsin (IRT).
- Sweat test (gold standard)
  - Sweat chloride
    - >60 mmol/L (on two occasions) is positive for CF.
    - <40 mmol/L is normal.
  - CFTR mutation analysis
  - Limited panel testing: Allele-specific polymerase chain reaction (PCR) identifies >90% of mutations; finite chance of false-negative finding. Full-sequence testing is more costly and time consuming.
  - Nasal potential difference (when sweat test and DNA testing inconclusive)
Follow-Up Tests & Special Considerations
To further investigate the presence of CF-related complications, these tests are generally ordered:

- Sputum culture (common CF organisms)
- Pulmonary function tests (PFTs)
- 72-hour fecal fat, stool elastase
- Oral glucose tolerance test (OGTT) annually after age 10 years
- Head CT: Abnormal sinus CT findings are nearly universal in CF and may include mucosal thickening, intraluminal sinus polyps, and sinus effusions.
- Chest CT (not routine): useful when unusual findings noted on CXR

Diagnostic Procedures/Other

- Flexible bronchoscopy
- Bronchoalveolar lavage

TREATMENT

GENERAL MEASURES

- Cystic Fibrosis Foundation guidelines call for yearly evaluation:
  - Four office visits, four respiratory cultures, PFTs q6mo, and at least one evaluation by a multidisciplinary team, including dietitian, GI, and social worker
  - PFT goals: >75% predicted for adults, >100% predicted for children <18 years old
  - Annual screening for ABPA for patients >6 years with total serum IgE concentration
  - Annual influenza vaccination for all CF patients age >6 months
  - Screen all adults for osteoporosis with a dual energy x-ray absorptiometry scan.
  - Annual measurement of fat-soluble vitamins to rule out vitamin deficiencies
  - Annual LFTs
  - Decrease exposure to tobacco smoke.
- All patients should be followed in a CF center (accredited sites are listed at [https://www.cff.org/](https://www.cff.org/)).
- Infant care:
  - Monthly visits for first 6 months of life and then every 2 months until 1 year of life
  - Fecal elastase testing and salt supplementation after diagnosis
  - Consider palivizumab for respiratory syncytial virus prophylaxis in infants with CF <2 years.

MEDICATION

- Pathogens for pulmonary infections: methicillin-resistant Staphylococcus aureus (MRSA) and methicillin-sensitive S. aureus (MSSA), Stenotrophomonas maltophilia, Pseudomonas aeruginosa, Burkholderia cepacia, nontuberculous mycobacteria (NTM)
  - Antibiotics for acute pulmonary infections should be prescribed according to most likely pathogen; most antibiotic courses are for 2 weeks.
- Pulmonary infections:
  - Antibiotics, oral
    - S. aureus: Bactrim (MRSA), doxycycline (MRSA) or cephalexin
    - P. aeruginosa: fluoroquinolones
– Antibiotics, inhaled
  o Tobi (tobramycin): for P. aeruginosa, nebulizer twice daily for 28 days; stop for 28 days and then resume use (2)[A].
  o Colistin (more commonly used in Europe)
  o Cayston (aerosolized aztreonam) (2)[A]
– Antibiotics, IV
  o S. aureus: cefazolin or nafcillin
  o MRSA: vancomycin or linezolid
  o P. aeruginosa: Zosyn or ceftazidime plus aminoglycoside (tobramycin)
  o Dual therapy synergistic (2)[A]

Medications recommended for chronic use in pulmonary disease:
– Recombinant human DNAse (dornase alfa) (2)[A]
– Hypertonic saline
– High-dose ibuprofen in patients 6 to 17 years old with FEV₁ ≥60 PPV
– Inhaled tobramycin or aztreonam in P. aeruginosa–positive patients
– Azithromycin in P. aeruginosa–positive patients
– Ivacaftor (VX770) and lumacaftor: CFTR potentiators approved in 2015 for patients with two copies of the F508del mutation. This vastly increases the number of people with CF eligible for this therapy (>50%).

Inhaled steroids are not recommended for chronic use in the absence of asthma or ABPA.
Insufficient evidence to recommend for or against chronic use: inhaled β-agonist, inhaled anticholinergics, leukotriene modifiers, inhaled colistin
  – Pancreatic enzymes (87.3%)
    o Often combined with H₂ blocker or proton pump inhibitor to increase effectiveness
  – Fat-soluble vitamin supplementation (A, D, E, and K)
  – Liver disease (cholestasis)
    o Ursodeoxycholic acid has not been proven effective.

ADDITIONAL THERAPIES
• High-frequency chest wall oscillation vest is the most widely used airway clearance technique.
• Aerobic exercise is used as an adjunct therapy for airway clearance.
  – CF-related bone disease: Consider bisphosphonate therapy.

SURGERY/OTHER PROCEDURES
• Timing for lung transplantation (bilateral) is polyfactorial. Key indications for referral are
  – FEV₁ <50% predicted for those with a rapidly declining FEV₁ (>20% relative decline within 12 months)
  – FEV₁ <40% predicted with markers of shortened survival
  – FEV₁ <30% predicted for all others
• 5-year posttransplant survival is up to 62%.
• Liver transplantation is reserved for progressive liver failure ± portal hypertension with GI bleeding.
• Nasal polypectomy in 4.5% of CF patients

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Pulmonary exacerbation (most common reason for admission)
• Bowel obstruction (due to DIOS, previously known as meconium ileus equivalent [MIE])
• Pancreatitis (in pancreatic-sufficient patients)
• CF exacerbations should always be admitted on contact precautions and private rooms.
• Nasal cannula oxygen when the patient is hypoxemic (SaO₂ <90%)
• Increased salt loss increases risk of hyponatremic hypochloremic dehydration.
• Cautious use of IV fluids with worsening lung disease
• Nursing assignments should involve only one CF patient per nurse for isolation purposes.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Upon discharge for a pulmonary exacerbation, follow-up with CF provider within 2 to 4 weeks.
• Routine clinic visits every 3 months, with airway cultures and pulmonary function testing
• Annual comprehensive nutritional evaluation

DIET
High-calorie, high-fat diet titrated to specific BMI goals established by the Cystic Fibrosis Foundation nutrition guidelines. If not meeting nutritional goals, dietitian, pancreatic enzyme, oral or tube supplemental feeding should be considered if indicated.

PATIENT EDUCATION
Cystic Fibrosis Foundation: https://www.cff.org

PROGNOSIS
• Median survival is 39.3 years.
• Progression of lung disease usually determines length of survival.

REFERENCES

ADDITIONAL READING

CODES
• ICD10
  • E84.9 Cystic fibrosis, unspecified
• E84.11 Meconium ileus in cystic fibrosis
• E84.0 Cystic fibrosis with pulmonary manifestations

CLINICAL PEARLS

• Meconium ileus is virtually pathognomonic for CF.
• When sweat test is equivocal, CFTR genetic testing is diagnostic.
• CF must be considered in any child with chronic diarrhea, especially if associated with poor growth or failure to thrive.
• All children with nasal polyps, digital clubbing, or bronchiectasis should be evaluated.
• A rapid decline in pulmonary function suggests the acquisition of resistant organisms (e.g., B. cepacia), CFRD, ABPA, or GERD.
DE QUERVAIN TENOSYNOVITIS
J. Herbert Stevenson, MD • Jonathan W. Smits, MD

BASICS

DESCRIPTION
- First identified in 1895 by Fritz De Quervain, de Quervain tenosynovitis is a painful condition due to stenosis of the tendon sheath in the 1st dorsal compartment of the radial aspect of the wrist.
- Caused by repetitive motion of the extensor pollicis brevis (EPB) and abductor pollicis longus (APL) over the radial styloid with resultant metaplastic changes of the surrounding tendon sheath.

EPIDEMIOLOGY
- The predominant age range is 30 to 50 years.
- Women are affected more commonly than men (1).
- With new occupational and professional demands, the prevalence of this condition is increasing gradually.

Incidence
- The overall incidence of de Quervain tenosynovitis is 0.9/1,000 person-years.
- For patients age >40 years, the incidence is 1.4/1,000 person-years compared with 0.6/1,000 person-years for those <20 years.
- Women have an incidence rate ratio of 2.8/1,000 person-years compared with 0.6/1,000 person-years in men.
- The incidence ratio rate of de Quervain tenosynovitis is 1.3/1,000 person-years in blacks and 0.8/1,000 person-years in whites (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Repetitive motions of the wrist and/or thumb result in microtrauma, metaplastic thickening of the tendons (EPB, APL), and narrowing of the surrounding tendon sheath.
- EPB and APL movement is resisted as they glide over the radial styloid causing pain with movements of the thumb and wrist.
- Among individual undergoing release of the 1st dorsal compartment, histopathology of the tendon sheaths was characterized by myxoid degeneration with dense fibrous tissue and mucopolysaccharide accumulation.
- Cadaveric analyses have identified an additional septum within the 1st dorsal compartment in 34–44% of individuals and subcompartmentalization has been reported in 86–94% of patients with de Quervain tenosynovitis (2).

RISK FACTORS
- Women age 30 to 50 years
- Pregnancy (primarily 3rd trimester and postpartum)
- African American
- Systemic diseases (e.g., rheumatoid arthritis)
- Participation in activities that include repetitive motion or forceful grasping with thumb and
wrist deviation such as golf, fly fishing, racquet sports, rowing, bicycling, video gaming, and more recently text messaging

- Repetitive movements with the hand/thumb requiring forceful grasping with wrist involving ulnar/radial deviation; dental hygienists, musicians, carpenters, assembly workers, and machine operators
- Recent analyses suggest that anatomic variability including tendon insertion variation and subcompartmentalization of the 1st dorsal compartment may be the greatest risk factors.

**GENERAL PREVENTION**
Avoid overuse or repetitive movements of the wrist and/or thumb associated with forceful grasping and ulnar/radial deviation.

**DIAGNOSIS**

**HISTORY**
- Repetitive motion activity; overuse of wrist or thumb
- Gradually worsening pain along the radial aspect of the thumb and wrist with certain movements, particularly ulnar deviation of the wrist
- Pregnancy
- Sports, leisure, and occupational history
- Trauma (rare)

**PHYSICAL EXAM**
- Pain over the radial styloid exacerbated when patients move the thumb or make a fist
- Crepitus with movement of the thumb
- Swelling over the radial styloid and base of the thumb
- Decreased range of motion of the thumb
- Pain over the 1st dorsal compartment on resisted thumb abduction or extension
- Tenderness may extend proximally or distally along the tendons with palpation or stress.
- Finkelstein test: The examiner grasps the affected thumb and deviates the hand sharply in the ulnar direction. A positive test occurs when there is pain along the distal radius.
- Eickhoff test: Patient grasps a flexed thumb, and the examiner deviates the wrist in an ulnar direction.
- Finkelstein test is more sensitive for determining tenosynovitis of the APL and EPB tendons (3)[A].

**DIFFERENTIAL DIAGNOSIS**
- Scaphoid fracture
- Scapholunate ligament tear
- Dorsal wrist ganglion
- Osteoarthritis of the 1st carpometacarpal (CMC) joint
- Flexor carpi radialis tendonitis
- Infectious tenosynovitis
- Tendonitis of the wrist extensors
- Intersection syndrome
- Trigger thumb
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Primarily a clinical diagnosis
- Radiographs of the wrist to rule out other pathology, such as CMC arthritis, if the diagnosis is in question
- MRI is the imaging test of choice to rule out coexisting soft tissue injury or wrist joint pathology.

Follow-Up Tests & Special Considerations
- Ultrasound can help to detect anatomic variations in the 1st dorsal extensor compartment of the wrist and target corticosteroid injections (4,5).
- Ultrasound imaging has been reported as 100% sensitive for detection of pathology (2).

Test Interpretation
Inflamed and thickened retinacular sheath of the tendon

TREATMENT

- Most cases of de Quervain tenosynovitis are self-limited.
- Rest and NSAIDs (3)[A]
- Ice (15 to 20 minutes, 5 to 6 times a day)
- Immobilization with a thumb spica splint (3)[A]
- Occupational therapy
- Acupuncture
- Corticosteroid injection (preferably ultrasound guided)
- Consider surgery if conservative measures fail >6 months.

GENERAL MEASURES

- If full relief is not achieved, a corticosteroid injection of the tendon sheath can improve symptoms.
- Anatomic variation, including subcompartmentalization of the 1st dorsal compartment or the EPB tendon traveling in a separate compartment, may complicate treatment. Ultrasound can distinguish these variants and improve anatomic accuracy of injections (4).
- Surgical release may be indicated after 3 to 6 months of conservative treatment if symptoms persist. Surgery is highly effective and has a relatively low rate of complications.

MEDICATION

First Line
Splinting, rest, and NSAIDs

Second Line
- Corticosteroid injection of the tendon sheath has shown significant cure rates. Additional injections are sometimes required.
- Corticosteroid injection plus immobilization is more effective than immobilization alone (6)[B].
- Ultrasound-guided percutaneous tenotomy, retinaculum release, and/or injection of platelet-rich plasma are newer techniques that show promise for treatment of de Quervain
tenosynovitis.

ISSUES FOR REFERRAL
Referral to a hand surgeon is indicated if there is no improvement with conservative therapy.

ADDITIONAL THERAPIES
- Hand therapy, along with iontophoresis/phonophoresis, may help improve outcomes in persistent cases.
- Patients may use thumb-stretching exercises as part of their rehabilitation.

SURGERY/OTHER PROCEDURES
- Indicated for patients who have failed conservative treatment.
- Endoscopic release may provide earlier relief, fewer superficial radial nerve complications, and greater patient satisfaction with resultant scar compared to open release (6)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hospitalization for care associated with surgical treatment.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Additional corticosteroid injection may be performed at 4 to 6 weeks if symptoms persist. Caution with repeat steroid injections.
- Avoid repetitive motions and activities that cause pain.

DIET
As tolerated.

PATIENT EDUCATION
Activity modification: Avoid repetitive movement of the wrist/thumb and forceful grasping.

PROGNOSIS
- Extremely good with conservative treatment.
- Complete resolution can take up to 1 year.
- 95% success rates have been shown with conservative therapy >1 year.
- Up to 1/3 of patients will have persistent symptoms.

COMPLICATIONS
- Most complications are secondary to treatment. These include GI, renal, and hepatic injury secondary to NSAID use.
- Nerve damage may occur during surgery.
- Hypopigmentation, fat atrophy, bleeding, infection, and tendon rupture have been reported as potential adverse events from corticosteroid injection. Ultrasound guidance reduces the rate of complications.
- If not appropriately treated, thumb flexibility may be lost due to fibrosis.

Algorithm: Pain in Upper Extremity
CODES
ICD10
M65.4 Radial styloid tenosynovitis [de Quervain]

CLINICAL PEARLS

- Repetitive movements of the wrist and thumb, and activities that require forceful grasping, are the most common causes of de Quervain tenosynovitis.
- Anatomic variations of the 1st dorsal compartment and metaplastic changes are identified in a majority of cases.
- Initial treatment is typically conservative.
- Corticosteroid injections are helpful and have lower complication rates if done under ultrasound guidance.
- Combined orthosis/corticosteroid injection approaches are more effective than either intervention alone.
- Ultrasound-guided percutaneous retinacular release and endoscopic surgery are helpful for recalcitrant cases.
DEEP VEIN THROMBOPHLEBITIS
Jaine L. McKenzie, MD ● Patricia Martinez Quinones, MD ● Keith O’Malley, MD, FACS

BASICS

DESCRIPTION
- Development of blood clot within the deep veins, usually accompanied by inflammation of the vessel wall
- Major clinical consequences are embolization (usually to the lung), recurrent thrombosis, and postphlebitic syndrome.

EPIDEMIOLOGY
- Age- and gender-adjusted incidence of venous thromboembolism (VTE) is 100 times higher in the hospital than in the community. Almost half of all VTEs occur either during or soon after discharge from a hospital stay or surgery.
- 10–30% of patients diagnosed with DVT and/or pulmonary embolism (PE) will die within 1 month of diagnosis
- Of patients with VTE, 20% complicated with PE. The 28-day deep venous thrombosis (DVT) fatality rate is 5.4%; at 1 year, 20%; at 3 years, 29%.

Incidence
- In the United States, VTE incidence is 50.4/100,000 person per year.
- Increased incidence in Caucasian and African American populations and with aging
- Most common site: lower extremity DVT
- Incidence in pregnancy: ~0.5 to 3/1,000 (1)
- 1–5% of central venous catheters are complicated by thrombosis (2).

Prevalence
- Variable; depends on medical condition or procedure
- At time of DVT diagnosis, as many as 40% of patients also have asymptomatic PE; conversely, 30% of patients diagnosed with PE do not have a demonstrable source.
- Present in 11% of patients with acquired brain injury entering neurorehabilitation

ETIOLOGY AND PATHOPHYSIOLOGY
Factors involved may include venous stasis, endothelial injury, and hypercoagulability (Virchow triad).

Genetics
- Factor V Leiden, the most common thrombophilia, is found in 5% of the population and in 10–65% of all VTE events and increases VTE risk 3- to 6-fold.
- Prothrombin G20210A is found in 3% of Caucasians; increases the risk of thrombosis ~3-fold

RISK FACTORS
- Acquired: previous DVT, cancer, immobilization, trauma, traumatic brain injury, obesity, recent major surgery, medications (oral contraceptives, estrogens, tamoxifen), obesity,
smoking, antiphospholipid syndrome, acute infectious process, thrombocytosis, pregnancy/puerperium, central venous catheters

**GENERAL PREVENTION**

- Mechanical thromboprophylaxis is recommended in patients with high bleeding risk and as adjunct to pharmacologic thromboprophylaxis.
- For acutely ill and for critically ill hospitalized patients at increased risk of thrombosis, low-molecular-weight heparin (LMWH), low-dose unfractionated heparin, or fondaparinux are recommended (3)[C].
- For most patients, prolonged secondary prophylaxis is not recommended.
- In patients undergoing major abdominal surgery for malignancy, LMWH for up to 4 weeks after surgery has been shown to decrease the incidence of VTE without increased bleeding.

**DIAGNOSIS**

**HISTORY**

- Higher clinical suspicion in patient with risk factors (see “Risk Factors” section)
- DVT is classified as provoked or idiopathic based on underlying risk factors.
- Clinical assessment of bleeding risk (bleeding with previous history of anticoagulation, history of liver disease, recent surgeries, history of GI bleed) is important prior to initiating treatment.
- Modified Wells criteria, a validated clinical prediction rule, is useful to determine pretest probability of having a DVT.
  - Active cancer (+1 point)
  - Calf swelling >3 cm compared to other leg (+1 point)
  - Collateral superficial veins (+1 point)
  - Pitting edema to symptomatic leg (+1 point)
  - Previous documented DVT (+1 point)
  - Swelling of entire leg (+1 point)
  - Localized tenderness along deep venous system (+1 point)
  - Paralysis, paresis, or recent cast immobilization of lower extremities (+1 point)
  - Recently bedridden >3 days or major surgery in past 4 weeks (+1 point)
  - Alternative diagnosis at least as likely (−2 points)
- Interpretation: Score of 0, DVT unlikely. Score of 1 to 2, moderate risk. Score of ≥3, DVT likely. D-dimer testing and/or ultrasound should follow based on Wells criteria score.

**PHYSICAL EXAM**

- Symptoms may present as pain, swelling, or discoloration but may be nonspecific or absent.
- Resistance to dorsiflexion of the foot (Homan sign) is unreliable and nonspecific.
- Edema, due to swelling of collateral veins, is the most specific symptom.
- Uncommonly, patients may have phlegmasia alba dolens (“milk leg”) or phlegmasia cerulean dolens due to arterial occlusion secondary to extensive DVTs.

**DIFFERENTIAL DIAGNOSIS**

Cellulitis, fracture, ruptured synovial cyst (Baker cyst), lymphedema, muscle strain/tear, extrinsic
compression of vein (e.g., by tumor/enlarged lymph nodes), compartment syndrome, and localized allergic reaction

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Routine laboratory testing (complete blood count, metabolic panel, coagulation studies) is not useful for diagnosis.
- D-dimer (sensitive but not specific; has high negative predictive value [NPV]), indicated in patients with low pretest probability of DVT or PE but not indicated high pretest probability patients; false positives in liver disease, inflammation, malignancy, trauma, pregnancy, and recent surgery.
- Patients with a prior DVT and those with malignancy have higher rates of VTE, which decreases the NPV of Wells criteria.
- Compression ultrasound (CUS): first-line imaging for DVT due to noninvasive nature and ease of use.
- In patients with suspected DVT, the diagnosis process should be guided by the assessment of the pretest probability.
  - Low pretest probability: high-sensitivity D-dimer assay sufficient to exclude DVT if negative. If positive, follow with CUS.
  - Moderate to high pretest probability: CUS initial test; if positive CUS, then treat DVT. If negative, no further testing is necessary; if continued concern, may repeat CUS in 24 hours.
- Other imaging modalities, such as CT venography and magnetic resonance venography, are rarely used but may be better than CUS for demonstrating new from old thrombosis.
- Contrast venography and impedance plethysmography are now rarely used.

**Follow-Up Tests & Special Considerations**

- In young patients and/or those of concern or with idiopathic/recurrent VTE, consider thrombophilia testing (factor V Leiden mutation, prothrombin G20210A genetic assay, ATIII functional assay, protein C functional assay, protein S antigen and functional assay and free S, phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant [drawn before initiation of heparin]).
- Risk of an underlying malignancy is more likely if recurrent VTE, risk 3.2 (95% CI 2.0–4.8). Unprovoked VTE, 4.6 times higher (vs. secondary); upper extremity DVT, not catheter associated; odds ratio (OR) 1.8, abdominal DVT; OR 2.2 (4), bilateral lower extremity DVT, OR 2.1 (4).

**TREATMENT**

**MEDICATION**

Consider starting therapy even before diagnosis confirmation in patients with high pretest probability and acceptable risk of bleeding.

- Anticoagulation is mainstay of therapy. In patients with PE or proximal DVT, long-term therapy (at least 3 months) is recommended. Duration of therapy after 3 months is case-by-case basis.
- Indefinite anticoagulation is considered if there is low risk of bleeding, if index event is unprovoked PE, and/or if D-dimer is positive 1 month after stopping anticoagulation (5).
Direct oral anticoagulants (dabigatran, rivaroxaban, apixaban, or edoxaban) recommended instead of vitamin K antagonists for the first 3 months of treatment in patients with lower extremity DVT or PE and no cancer (4)[B]

Use and choice of anticoagulation should be considered based on patient’s history, bleeding risk, cost, and ease of compliance.

**First Line**

- Unfractionated heparin
  - IV drip: initial dose of 80 U/kg followed by continuous infusion of 18 U/kg/hr. Target activated partial thromboplastin time (aPTT) ratio >1.5 times control. Monitor aPTT every 6 hours and adjust infusion rate accordingly until two successive values are within therapeutic range.
- LMWH
  - Enoxaparin (Lovenox): 1 mg/kg/dose SC q12h or 1.5 mg/kg daily
  - Dalteparin (Fragmin): 200 U/kg SC q24h
- Direct and indirect factor Xa inhibitors
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight = 50 to 100 kg), or 10 mg (body weight >100 kg) SC once daily
  - Rivaroxaban (Xarelto): 15 mg PO twice daily with food for the first 3 weeks then 20 mg PO every day
  - Apixaban (Eliquis): 10 mg PO twice daily for 1 week followed by 2.5 to 5.0 mg PO twice daily
  - Edoxaban (Savaysa): 60 mg PO daily (>60 kg), 30 mg PO daily (≤60 kg)
- Thrombin inhibitors
  - Dabigatran (Pradaxa): 150 mg PO twice daily for creatinine clearance >30 mL/min
- Vitamin K antagonists
  - Warfarin (Coumadin): Start with 2 to 5 mg/day. Adjust to a target INR of 2 to 3; overlap with parenteral anticoagulant for minimum of 5 days until therapeutic INR sustained ≥24 hours.
- Adverse effects
  - All anticoagulants increase risk of bleeding.
  - Heparin and LMWH can also cause heparin-induced thrombocytopenia (HIT) (LMWH has lower risk) and injection site irritation.
  - Warfarin is teratogenic.
  - Dosage adjustments may be required for patients with decreased creatinine clearance.

**Second Line**

Heparin can be given by intermittent SC self-injection.

**Pregnancy Considerations**

- Warfarin (Coumadin) is a teratogen. It is contraindicated in pregnancy but is safe during breastfeeding.
- LMWH are recommended over unfractionated heparin for treatment of acute DVT and PE in pregnancy (1)[B].
- Enoxaparin, dalteparin, fondaparinux, and apixaban are pregnancy Category B.
- Dabigatran, rivaroxaban, edoxaban are pregnancy Category C.

**SURGERY/OTHER PROCEDURES**
In selected patients with proximal DVT (acute iliofemoral DVT <14 days, good functional status, >1 year of life expectancy), may consider catheter-directed thrombolysis/open thrombectomy (6).

- Thrombolysis (systemic or catheter directed) reduces incidence of postthrombotic syndrome (PTS) after a proximal (iliofemoral or femoral) DVT by 1/3.
- Thrombectomy is recommended in patients with limb-threatening ischemia due to iliofemoral venous outflow obstruction (6).
- Inferior vena cava filter
  - Not routinely inserted in patients with acute DVT
  - May be considered in patients with DVT or PE with absolute contraindication to anticoagulation or recurrent embolism despite adequate anticoagulation
  - Special considerations can be given to patients who are chronically immobile, such as spinal cord injury patients.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- In patients with acute PE, if the following criteria are met, then hospital admission is not necessary. Patients who meet these criteria but are admitted may be discharged early (<5 days of inpatient treatment) (4):
  - Patient is clinically stable with good cardiopulmonary reserve.
  - No recent bleeding, severe renal or liver disease, or severe thrombocytopenia platelets <70,000
  - Expected to be compliant
  - Patient feels well enough to be treated at home.
- Admission for respiratory distress, elevated cardiac biomarkers, right ventricular dysfunction, candidate for thrombolysis, active bleeding, renal failure, phlegmasia alba dolens, phlegmasia cerulea dolens, history of HIT
- In medically stable and properly anticoagulated patients, overlap of anticoagulation and warfarin monitoring may be done as an outpatient.
- Limb elevation and graduated compression stockings for symptomatic relief

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Resumption of normal activity with avoidance of prolonged immobility
- Compression stockings not routinely recommended for prevention of PTS after acute DVT (4) but can be used for patients who already present with symptoms of PTS

Patient Monitoring
- Monitor platelet count while on heparin, LMWH, and fondaparinux for HIT.
- An anti-Xa activity level may help guide LMWH titration of therapy.
- Investigate significant bleeding (e.g., hematuria or GI hemorrhage) because anticoagulant therapy may unmask a preexisting lesion (e.g., cancer, peptic ulcer disease, or arteriovenous [AV] malformation).

PATIENT EDUCATION
Dietary habits should be discussed when warfarin is initiated to ensure that intake of vitamin K–

rich foods is monitored.

PROGNOSIS
- 20% of untreated proximal (iliofemoral, femoral, or popliteal) lower extremity DVTs progress to PE, and 10–20% of those are fatal. However, with anticoagulant therapy, mortality is decreased 5- to 10-fold.
- DVT confined to the infrapopliteal veins has a small risk of embolization but can propagate proximally.
- Up to 75% of patients with symptomatic DVT present with PTS after 5 to 10 years.

COMPLICATIONS
- PE (fatal in 10–20%), arterial embolism (paradoxical embolization) with AV shunting, chronic venous insufficiency, PTS, treatment-induced hemorrhage, soft tissue ischemia associated with massive clot and high venous pressures; phlegmasia cerulea dolens (rare but a surgical emergency)

CODES

ICD10

- I80.209 Phlbts and thrombophlb of unsp deep vessels of unsp low extrm
- I80.299 Phlebitis and thrombophlb of deep vessels of unsp low extrm
- I80.10 Phlebitis and thrombophlebitis of unspecified femoral vein

CLINICAL PEARLS

- Many cases of VTE are asymptomatic.
- At time of DVT diagnosis, as many as 40% of patients also have asymptomatic PE.
- Wells criteria are useful to determine the pretest probability of a DVT, but follow-up testing and/or imaging should be done if moderate to high probability.
- Choice of anticoagulant therapy should be individualized based on patient’s history and compliance.
DEHYDRATION
Tu Dan (Kathy) Nguyen, MD

BASICS

DESCRIPTION
- A state of negative fluid balance; strictly defined as free water deficiency
- The two types of dehydration:
  - Water loss
  - Salt and water loss (combination of dehydration and hypovolemia)

EPIDEMIOLOGY
- Responsible for 10% of all pediatric hospitalizations in the United States
- Gastroenteritis, one of its leading causes, accounts to 13/1,000 children <5 years of age annually in the United States.

Incidence
- More than half a million hospital admissions annually in the United States for dehydration
- Of hospitalized older persons, 8% are dehydrated (1).
- Worldwide, ~3 to 5 billion cases of acute gastroenteritis occur each year in children <5 years of age, resulting in nearly 2 million deaths.

ETIOLOGY AND PATHOPHYSIOLOGY
- Negative fluid balance occurs when ongoing fluid losses exceed fluid intake.
- Fluid losses can be insensible (sweat, respiration), obligate (urine, stool), or abnormal (diabetes, vomiting, osmotic diuresis in diabetic ketoacidosis).
- Negative fluid balance can lead to severe intravascular volume depletion (hypovolemia) and end-organ damage from inadequate perfusion.
- The elderly are at increased risk as kidney function, urine concentration, thirst sensation, aldosterone secretion, release of vasopressin, and renin activity are all significantly lowered with age.
- Decreased intake
- Increased output: vomiting, diarrheal illnesses, sweating, frequent urination
- “Third spacing” of fluids: effusions, ascites, capillary leaks from burns, or sepsis

Genetics
Some causes of dehydration have a genetic component (diabetes), whereas others do not (gastroenteritis).

RISK FACTORS
- Children <5 years of age at highest risk
- Elderly
- Decreased cognition
- Lack of access to water such as in critically sick intubated patients

GENERAL PREVENTION
- Patient/parent education on early signs of dehydration
Universal precautions (including hand hygiene)

**Geriatric Considerations**
Systematically assessing risk factors helps with early prevention and management of dehydration in the elderly, especially those in long-term care facilities.

</table>

**COMMONLY ASSOCIATED CONDITIONS**
- Hypo-/hypernatremia
- Hypokalemia
- Hypovolemic shock
- Renal failure

**DIAGNOSIS**
Calculate percent dehydration = (preillness weight – illness weight)/preillness weight × 100. Supplement this along with the ongoing fluid loss.

**HISTORY**
- Fever
- Intake (including description and amount)
- Diarrhea (including duration, frequency, consistency, ± mucus/blood)
- Vomiting (including duration, frequency, consistency, ± bilious/nonbilious)
- Urination pattern
- Sick contacts
- Medication history (e.g., diuretics, laxatives)

**PHYSICAL EXAM**
- The most useful signs for identifying dehydration in children are prolonged capillary refill time, abnormal skin turgor, and abnormal respiratory pattern.
- Vitals: pulse, BP, temperature
- Orthostatic vital signs: Take BP and heart rate (HR) while supine, sitting, and standing.
  - Systolic BP decrease of 20 mm Hg, diastolic BP decrease by 10 mm Hg, or HR increase by
20 bpm suggests hypovolemia (2).

- Weight loss: <5%, 10%, or >15%
- Mental status
- Head: sunken anterior fontanelle (for infants)
- Eyes: sunken, ± tear production
- Mucous membranes: tacky, dry, or parched
- Capillary refill: ranges from brisk to >3 seconds
- Darker urine color

**DIFFERENTIAL DIAGNOSIS**

- Decreased intake: ineffective breastfeeding, inadequate thirst response, anorexia, malabsorption, metabolic disorder, obtunded state
- Excessive losses: gastroenteritis, diarrhea, febrile illness, diabetic ketoacidosis, hyperglycemia, hyperosmolar hyperglycemic state, diabetes insipidus, intestinal obstruction, sepsis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- For mild dehydration: generally not necessary
- For moderate to severe dehydration
  - Electrolytes, BUN, creatinine, and glucose
  - Urinalysis (specific gravity, hematuria, glucosuria)
- Imaging does not play a role in the diagnosis of dehydration, unless the specific condition causing the dehydration requires imaging.
- In adults, inferior vena cava collapsibility is a surrogate marker for volume status.

**Pediatric Considerations**

Infants and the elderly may not concentrate urine maximally, making urine specific gravity less helpful.

**TREATMENT**

**MEDICATION**

**First Line**

- Oral rehydration is the first-line treatment in dehydrated children. If this is unsuccessful, use IV rehydration. If IV unobtainable, nasogastric (NG) or intraosseous (IO) rehydration can be considered (3).
- Oral rehydration is the first-line treatment in dehydrated adults as long as they can tolerate fluids. Have a lower threshold for IV rehydration if needed.
- If the patient is experiencing excessive vomiting, consider using an antiemetic.
- Ondansetron (PO/IV) may be effective in decreasing the rate of vomiting, improving the success rate of oral hydration, preventing the need for IV hydration, and preventing the need for hospital admission (4,5).
- Other antiemetics can be used.

**Second Line**

- Loperamide may reduce the duration of diarrhea compared with placebo in children with mild
to moderate dehydration (two randomized controlled trials [RCTs] yes, one RCT no).

- In children ages 3 to 12 years with mild diarrhea and minimal dehydration, loperamide decreases diarrhea duration and frequency when used with oral rehydration.

**Pediatric Considerations**

Given a higher risk for serious adverse events, loperamide is not indicated for children <3 years of age with acute diarrhea.

**ISSUES FOR REFERRAL**

- For severe dehydration, critical care referral and ICU-level care may be warranted.
- Surgical consultation for acute abdominal issues

**SURGERY/OTHER PROCEDURES**

For specific underlying causes of dehydration, such as intestinal obstruction or appendicitis

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Intractable vomiting/diarrhea
- Electrolyte abnormalities
- Hemodynamic instability
- Inability to tolerate oral rehydration therapy (ORT)
- Stabilize airway, breathing, circulation.
- If mild dehydration, try ORT.
- If excessive vomiting/severe dehydration with shock, start IV access and IV fluids immediately.
- IV fluids
  - Stage I
    - For moderate to severe dehydration in children: isotonic saline or Ringer lactate solution bolus of 10 to 20 mL/kg; may repeat up to 60 mL/kg; if still hemodynamically unstable, consider colloid replacement (blood, albumin, fresh frozen plasma) and address other causes for shock.
    - For moderate to severe hypovolemia in adults: isotonic saline or Ringer lactate 20 mL/kg/hr until normal state of consciousness returns/vital signs stabilize. Also consider colloid replacement if continued fluids required beyond 3 L.
  - Stage II: Replace fluid deficit along with maintenance over 48 hours; fluid deficit = preillness weight – illness weight
  - An alternative IV treatment option for moderate (10%) dehydration in children
    - Bolus with NS/LR at 20 mL/kg for 1 hour
    - Replete fluid deficit with D5 1/2 NS + 20 mEq KCl/L at 10 mL/kg for 8 hours (hours 2 to 9).
    - Replete 1.5 for maintenance fluids with D5 1/4 NS + 20 mEq/L of KCl for 16 hours (hours 10 to 24).
  - An alternative to IV fluids is hypodermoclysis, the SC infusion of fluids into the body (adults).
    - Indications: hydration of patients with mild to moderate dehydration who do not tolerate oral intake because of cognitive impairment, severe dysphagia, advanced terminal illness, or intractable vomiting. It is also indicated to prevent dehydration, especially in frail elderly residents living in long-term care settings who reject the oral route for any reason; useful technique for patients with difficult IV access
Contraindications: severe dehydration or shock, patients with coagulopathy or receiving full anticoagulation, patients with severe generalized edema (anasarca) or congestive heart failure, and those with fluid overload (6)

- Strict inputs and outputs: oral and IV input and output of urine and stool, which may include weighing wet diapers
- Discharge criteria
  - Input > output
  - Underlying etiology treated and improving

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Activity as tolerated
- If mild to moderate dehydration, the patient may be mobile without restrictions, although watch for orthostasis/falls.
- If moderate to severe dehydration, bed rest

Patient Monitoring
Ongoing surveillance for recurrence

DIET
- Bland food bananas, rice, applesauce, toast (BRAT) diet
- If diarrhea, lactose-free feeds may reduce the duration of diarrhea in children with mild to severe dehydration, compared with lactose-containing feeds.
- Small frequent sips of room temperature liquids
- Oral rehydration solutions are available commercially.
- Continue breastfeeding ad lib.

PATIENT EDUCATION
- Patients should seek medical care if they (or their child) feel faint or dizzy when rising from a sitting or lying position, becomes lethargic and/or confused, or complains of a rapid HR.
- Patients should call their physician if they are unable to keep down any fluids, vomiting has been going on >24 hours in an adult or >12 hours in a child, diarrhea has lasted >2 days in an adult/child, or an infant/child is much less active than usual or is very irritable.
- http://www.mayoclinic.org/diseases-conditions/dehydration/basics/definition/con-20030056

PROGNOSIS
Self-limited if treated early; potentially fatal if untreated and persistent

COMPLICATIONS
- Seizures
- Renal failure
- Cardiovascular arrest

REFERENCES

SEE ALSO
Oral Rehydration

CODES

ICD10
- E86.0 Dehydration
- E87.1 Hypo-osmolality and hyponatremia
- E86.1 Hypovolemia

CLINICAL PEARLS
- Dehydration is the result of a negative fluid balance and is a common cause of hospitalization in both children and the elderly.
- Begin by assessing the level of dehydration, determining the underlying cause, and calculating necessary replacement.
- Treatment is directed at restoring fluid balance via oral rehydration (first line) therapy or IV fluids and treating underlying causes.
BASICS

DESCRIPTION
- A temporary neurocognitive complication of illness and/or medication(s), especially common in older patients, manifested by new confusion and impaired attention
- A medical emergency requiring immediate evaluation to decrease morbidity and mortality
- System(s) affected: neurologic
- Synonym(s): acute confusional state, altered mental status, organic brain syndrome, acute mental status change, encephalopathy

Epidemiology
- Predominant age: older persons
- Predominant sex: male = female

Incidence
- >50% in older intensive care unit patients
- 11–51% in postoperative patients
- 10–40% in hospitalized older patients
- 20–22% in nursing home/post–acute-care patients

Prevalence
- 1–2% in outpatients
- 8–17% in older ED patients
- 14% in older postacute care patients
- 18–35% in hospitalized general medicine patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial: believed to result from a decline in physiologic reserves with aging, resulting in a vulnerability to new stressors
- Disturbance in global cortical functioning. Neuropathophysiology is not clearly defined; cholinergic deficiency, dopamine excess, and neuroinflammation are leading hypotheses.
- Often interaction between predisposing and precipitating risk factors
- With more predisposing factors (i.e., frail patients), fewer precipitating factors needed to cause delirium
- If few predisposing factors (e.g., very robust patients), more precipitating factors needed to cause delirium
- Multicomponent approach addressing contributing factors can reduce incidence and complications.

RISK FACTORS
- Predisposing risk factors
  - Advanced age: >70 years
  - Preexisting cognitive impairment
– Functional impairment
– Dehydration; high blood urea nitrogen:creatinine ratio
– History of alcohol abuse
– Malnutrition
– Hearing or vision impairment
– Multiple comorbidities

**Precipitating risk factors**
– Severe illness in any organ system(s)
– Medical devices (urinary catheter, restraints)
– Polypharmacy (≥5 medications)
– Specific medications, especially benzodiazepines, opioids, and anticholinergics
diphenhydramine, high-dose neuroleptics
– Pain
– Any iatrogenic event
– Surgery
– Sleep deprivation

**GENERAL PREVENTION**
Follow treatment approach.

**COMMONLY ASSOCIATED CONDITIONS**
Multiple but most common are the following:

● New medicine or medicine changes
● Infections (especially lung, urine, and blood stream, but consider meningitis as well)
● Toxic metabolic (especially low sodium, elevated calcium, renal failure, and hepatic failure)
● Heart attack or stroke
● Alcohol or drug withdrawal
● Preexisting cognitive impairment increases risk.

**DIAGNOSIS**
Diagnosis is made using a careful history, behavioral observation, and cognitive assessment.

● Diagnostic and Statistical Manual of Mental Disorders, 5th edition diagnostic criteria include (1):
  – Disturbance in attention and awareness
  – Change in cognition not due to dementia or coma
  – Presence of an additional disturbance in cognition (e.g., memory deficit, language, visuospatial ability, disorientation, or perception)
  – Onset over short period (hours to days) and fluctuates during course of day
  – Evidence from history, exam, or lab that disturbance is caused by physiologic consequence of medical condition, intoxicating substance, medication use, or more than one cause.

● The Confusion Assessment Method (CAM) is the most well validated and tested clinical tool (sensitivity 94–100% and specificity 90–95% (2)[B]) and has been adapted for ICU setting in adults (CAM-ICU) and children (pediatric CAM-ICU [pCAM-ICU]).

**ALER**
● Four key diagnostic features of the CAM:
– Acute change in mental status
– Fluctuating course
– Inattention
– Disorganized thinking or altered level of consciousness

Several nondiagnostic symptoms may be present:
– Short- and long-term memory problems
– Sleep–wake cycle disturbances
– Hallucinations and/or delusions
– Emotional lability
– Tremors and asterixis

Subtypes based on level of consciousness
– Hyperactive delirium (15%): Patients are loud, agitated, restless, and disruptive.
– Hypoactive delirium (20%): quietly confused; sleepy; may sit and not eat, drink, or move
– Mixed delirium (50%): features of both hyperactive and hypoactive delirium
– Normal consciousness delirium (15%): still displays disorganized thinking, along with acute onset, inattention, and fluctuating mental status
– Subsyndromal delirium (23%): some delirium symptoms but does not progress to full delirium

HISTORY
– Time course of mental status changes
– Recent medication changes
– Symptoms of infection
– New neurologic signs
– Abrupt change in functional ability

PHYSICAL EXAM
– Comprehensive cardiorespiratory exam is essential.
– Focal neurologic signs are usually absent.
– Mini-Mental State Examination (MMSE) is the most well-known and studied cognitive screen, but it may not be the most appropriate in an acute care setting; shorter cognitive screens have been studied in delirious patients (i.e., Short Blessed Test [SBT], Brief Alzheimer Screen [BAS], and Ottawa 3DY) and may be helpful if performed serially over time. Most patients will perform poorly if delirium is present; dementia cannot be diagnosed when delirium is present.
– Gastrointestinal/genitourinary exam for constipation/urinary retention

DIFFERENTIAL DIAGNOSIS
– Depression (disturbance of mood, normal level of consciousness, fluctuates weeks to months)
– Acute stress disorder (disturbance of mood, normal level of consciousness, precipitated by traumatic event)
– Bipolar disorder, manic episode (pressured speech, impulsivity, fluctuates weeks to months, rarely sudden onset in older adults)
– Dementia (insidious onset, memory problems, normal level of consciousness, fluctuates days to weeks)
– Psychosis (rarely sudden onset in older adults)
– Seizure disorders (i.e., nonconvulsive status epilepticus)
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Guided by history and physical exam
  - Complete blood count with differential
  - Comprehensive metabolic panel (CMP)
  - Urinalysis, urine culture
  - Blood culture
  - Medication levels (digoxin, theophylline, antiepileptics) where applicable
- Chest radiograph for most
- Electrocardiogram as necessary
- Others, if indicated by history and exam (e.g., lactic acid, cortisol, vitamin B₁₂, C-reactive protein)

Follow-Up Tests & Special Considerations
- If lab tests listed above do not indicate a precipitator of delirium, consider
  - Arterial blood gases
  - Troponin
  - Toxicology screen
  - Ammonia
  - Thyroid-stimulating hormone
  - Thiamine
- Noncontrast-enhanced head CT scan if
  - Unclear diagnosis
  - Recent fall
  - Receiving anticoagulants
  - New focal neurologic signs
  - Ruling out mass before lumbar puncture

Diagnostic Procedures/Other
- Lumbar puncture (rarely necessary)
  - Perform if clinical suspicion of a central nervous system bleed, malignancy-related syndrome, or infection is high.
- Electroencephalogram (rarely necessary)
  - Consider after above evaluation if cause remains unclear or suspicion of seizure activity.

TREATMENT
- The best treatment is prevention, and there is strong evidence for multicomponent non-pharmacological strategies
- Strong evidence for multicomponent non-pharmacological interventions
- The Hospital Elder Life Program (HELP) is a widely used approach (2):
  - Address acute medical issues (e.g., treat underlying disorder, stabilize vitals, maintain hydration
  - Reorientation strategies (provide eyeglasses, hearing aids, interpreters, encourage family involvement)
  - Drug adjustments (avoid or reduce psychoactive drugs, prioritize nonpharmacologic
approaches)
– Maintain safe mobility (avoid restraints, tethers, bed alarms; ambulate patients; encourage self-care)
– Normalize sleep–wake cycle (discourage napping, open curtains during day, prioritize uninterrupted sleep)
– Pharmacologic management of symptoms (reserve for severe circumstances)

Addressing six risk factors (i.e., cognitive impairment, sleep deprivation, dehydration, immobility, vision impairment, and hearing impairment) in at-risk hospitalized patients can reduce the incidence of delirium by 33%.

GENERAL MEASURES

• Postoperative patients should be monitored for
  – Myocardial infarction/ischemia
  – Infection (i.e., pneumonia, urinary tract infection)
  – Pulmonary embolism
  – Urinary or stool retention (attempt catheter removal by postoperative day 2)
  – Anemia/bleeding
• Anesthesia route (general vs. epidural) may affect the risk of delirium. Depth of anesthesia likely affects risk of delirium
• ICU sedation and avoidance of benzodiazepines may reduce risk.
• Multifactorial treatment: Identify contributing factors and provide preemptive care to avoid iatrogenic problems, with special attention to
  – CNS oxygen delivery (attempt to attain):
    o $\text{SaO}_2 > 90\%$ with goal of $\text{SaO}_2 > 95\%$
    o Systolic BP $< 2/3$ of baseline or $> 90 \text{ mm Hg}$
    o Hematocrit $> 30\%$
  – Fluid/electrolyte balance
    o Sodium, potassium, and glucose normal (glucose $< 300 \text{ mg/dL}$ in diabetics)
    o Treat fluid overload or dehydration.
  – Treat pain
    o Schedule acetaminophen (650 mg TID–QID) if constant pain; avoid if LFT elevation noted.
    o Opioids, morphine, oxycodone may be used for breakthrough pain.

ALERT

• Avoid meperidine (Demerol).
• Eliminate unnecessary medications.
  – Investigate new symptoms as potential medication side effects (i.e., Beers medications).
• Regulate bowel/bladder function.
  – Bowel movement at least every 48 hours
  – Screen for urinary retention.
• Prevent major hospital-acquired problems.
  – Use a pressure-reducing mattress.
  – Avoid urinary catheters.
  – Encourage incentive spirometry.
  – Venous thromboembolism (VTE) prophylaxis if bedfast
  – Early mobilization
Environmental stimulation
- Glasses and hearing aids
- Clock and calendar
- Soft lighting with curtains open during the day
- Music and television, if desired

Sleep
- Quiet and dark environment
- Soft music
- Therapeutic massage

Restraints increase risk of delirium and falls/injury.
- Use as a last resort for patients at risk for self-injury or risk for injuring caregivers. Remove as soon as possible.

MEDICATION
- Nonpharmacologic approaches are preferred for initial treatment, but medication may be needed for agitation and injurious behaviors, especially in the ICU setting.
- Medications treat the symptoms and do not address the underlying cause.
- No medication is FDA approved for delirium.
- Medications should not be used as prophylaxis.

First Line
- For symptomatic management of intolerable agitation or hallucinations:
  - Antipsychotics (in alphabetical order)
    - Aripiprazole (Abilify) 2 to 5 mg PO daily to BID
    - Haloperidol (Haldol): initially, 0.25 to 0.50 mg PO/IM; reevaluate and potentially redose hourly until symptoms controlled and then use effective dose up to QID PRN. Critical care guidelines do not support use of antipsychotics for prevention of ICU delirium.
    - Olanzapine (Zyprexa) 2.5 to 5.0 mg PO daily to BID
    - Quetiapine (Seroquel) 12.5 to 25.0 mg PO BID–TID
    - Risperidone (Risperdal) 0.25 to 0.50 mg PO daily
  - Contraindications: Avoid haloperidol in patients with parkinsonism or Parkinson disease.
  - Precautions: Antipsychotics may cause extrapyramidal effects and increase fall risk.
  - Antipsychotics may prolong the QT interval. Aripiprazole (Abilify) has minimal or no QT prolonging effect.
- For management of sedation in ICU patient
  - Alpha 2-agonist dexmedetomidine is preferred for sedation in ICU patients and is the only medication that has been found to possibly shorten delirium duration. The primary adverse effects of this medication include hypotension and bradycardia. Some studies have also found use of clonidine as an oral bridge off of dexmedetomidine.
- Melatonin and melatonin agonists are gaining interest as sleep aids in ICU patients.

Second Line
- Benzodiazepines should generally be avoided except in alcohol withdrawal, if patient taking a benzodiazepine regularly at baseline, or antipsychotic is contraindicated. Benzodiazepines can cause delirium. Lorazepam (Ativan): initially, 0.25 to 0.50 mg PO/IM/IV TID–QID PRN; may need to adjust to effect (caution in impaired liver and renal function)
- Cholinesterase inhibitors should be avoided. Multiple trials demonstrate adverse events with
cholinesterase inhibitors in the management of delirium; evidence does not support their use.

ISSUES FOR REFERRAL
Geriatric, psychiatric, or neurologic consultation is helpful if delirium is not easily explainable or resolving after full evaluation. Interprofessional team approach is best.

ADDITIONAL THERAPIES
Early mobilization is critical.
- Out of bed several hours daily starting on hospital day 2 (or postoperative day 1) if no contraindications

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Cognitive engagement is key.
- New delirium is a medical emergency and requires admission, except in the setting of hospice care.
- IV fluids as needed for dehydration
- Monitor for the development of delirium.
- Assessment of precipitants/contributing factors (infection, pain, constipation, urinary retention)
- Reorient; maintain day/night orientation.
- Skin care and turning regimen for immobile patients
- Maintain and encourage mobility.
- Encourage family presence and participation.
- Discharge criteria
  - Resolution of precipitating factor(s)
  - Safe discharge site if delirium is slow to resolve

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- If delirium at discharge, often needs postacute facility care and ongoing assessment for resolution
- If no delirium at discharge, follow up with primary care physician in 1 to 2 weeks.

Patient Monitoring
- Evaluate and assess mental status daily.
- Continued evaluation for precipitating cause(s)

DIET
- Liberalize diet to increase oral intake.
- Nutritional supplements if oral intake is poor
- Consider temporary nasogastric tube if unable to eat and bowels are working.

PROGNOSIS
- May take weeks/months to fully resolve
- Usually improves with treatment of underlying condition(s); can lead to chronic cognitive impairment
- Delirium increases a person’s 1-year mortality risk.
COMPLICATIONS
- Falls and functional decline
- Pressure ulcers and malnutrition
- Future cognitive dysfunction
- Higher risk for institutionalization
- Death

REFERENCES

SEE ALSO
- Dementia; Depression; Substance Use Disorders
- Algorithm: Delirium

CODES
ICD10
- R41.0 Disorientation, unspecified
- F19.931 Oth psychoactive substance use, unsp w withdrawal delirium
- F10.231 Alcohol dependence with withdrawal delirium

CLINICAL PEARLS
- The criteria for delirium include an acute onset of fluctuating mental status, inattention, and either disorganized thinking or altered level of consciousness.
- Primary treatment for delirium is to identify and treat the underlying causes.
- Nonpharmacologic measures are preferable.
- Delirium may not resolve as soon as the treatable contributors resolve; may take weeks or months
DEMENTIA
Umer Farooq, MD ● Hammad Mohsin, MD

BASICS

DESCRIPTION
Dementia refers to cognitive decline from previous level of performance in various cognitive domains (attention, executive function perceptual-motor, social cognition, and memory). The cognitive deficits interfere significantly with ADLs (for major only) and do not occur exclusively in the context of delirium or any other mental disorder.

- DSM-5 classifies dementias under neurocognitive disorders (major and mild) and specifies the cause of neurocognitive decline secondary to the following:
  - Alzheimer dementia (AD)
    - Progressive cognitive decline; most common age >65 years
  - Vascular dementia (VaD)
    - Usually correlated with a cerebrovascular event and/or cerebrovascular disease
    - Stepwise deterioration with periods of clinical plateaus
  - Lewy body dementia
    - Fluctuating cognition associated with parkinsonism, hallucinations and delusions, gait difficulties, and falls
  - Frontotemporal dementia
    - Language difficulties, personality changes, and behavioral disturbances
  - Creutzfeldt-Jakob disease (CJD)
    - Very rare; rapid onset
  - HIV dementia
  - Substance-/medication-induced neurocognitive disorder

EPIDEMIOLOGY

Prevalence
- In patients age ≥65 years
  - AD: 5–10% (age 65 to 70 years); 25% (≥70 years)
  - VaD: 0.2% (age 65 to 70 years); up to 16% (≥70 years)
  - Other: 13%
- Estimated 5.4 million Americans had AD in 2010.
  - 5 million >65 years of age; 200,000 <65 years
  - Prevalence expected to double by 2030

ETIOLOGY AND PATHOPHYSIOLOGY

- AD: involves β-amyloid protein accumulation and/or neurofibrillary tangles (NFTs), synaptic dysfunction, neurodegeneration, and eventual neuronal loss
- Age, genetics, systemic disease, smoking, and other host factors may influence the β-amyloid accumulation and/or the pace of progression toward the clinical manifestations of AD.
- VaD: cerebral atherosclerosis/emboli with clinical/subclinical infarcts

Genetics
- AD: positive family history in 50%, but 90% AD is sporadic: APOE4 increases risk but full
role unclear.

- Familial/autosomal dominant AD accounts for <5% AD: amyloid precursor protein (APP), presenilin-1 (PSEN-1), and presenilin-2 (PSEN-2).

**RISK FACTORS**

- Age; sex: female > male
- Genetic predisposition
- Hypertension: AD; VaD
- Hypercholesterolemia: AD; VaD
- Diabetes: VaD
- Cigarette smoking: VaD
- Endocrine/metabolic abnormalities: hypothyroidism, Cushing syndrome; thiamine and vitamin B<sub>12</sub> deficiency
- Chronic alcoholism, other drugs
- Lower educational status
- Head injury early in life
- Sedentary lifestyle

**GENERAL PREVENTION**

- Treat reversible causes of dementia, such as drug-induced, alcohol-induced, and vitamin deficiencies.
- Treat hypertension, hypercholesterolemia, and diabetes.
- No evidence for statins (or any other specific medication) to prevent onset of dementia (1)[A]
- BP control and low-dose aspirin may prevent or lessen cognitive decline in VaD.

**COMMONLY ASSOCIATED CONDITIONS**

- Anxiety and major depression
- Psychosis (delusions; delusions of persecution are common)
- Delirium
- Behavioral disturbances (agitation, aggression)
- Sleep disturbances

**DIAGNOSIS**

**HISTORY**

Probable diagnosis AD (2):

- Age between 40 and 90 years (usually >65 years)
- Progressive cognitive decline of insidious onset
- No disturbances of consciousness
- Deficits in areas of cognition
- No other explainable cause of symptoms
- Specifically rule out thyroid disease, vitamin deficiency (B<sub>12</sub>), grief reaction, and depression.
- Supportive factors: family history of dementia

**PHYSICAL EXAM**

- Often normal physical
- No disturbances of consciousness
Cognitive decline demonstrated by standardized instruments, including the following:
- Mini-Mental State Examination (MMSE)
- Montreal Cognitive Assessment (MoCA) test
- ADAS-Cog
- Clock drawing test
- Use caution in relying solely on cognition scores, especially in those with learning difficulty, language barriers, or similar limitations.

DIFFERENTIAL DIAGNOSIS
- Major depression
- Medication side effect
- Chronic alcohol use
- Delirium
- Subdural hematoma
- Normal pressure hydrocephalus
- Brain tumor
- Thyroid disease
- Parkinson disease
- Vitamin B$_{12}$ deficiency
- Toxins (aromatic hydrocarbons, solvents, heavy metals, marijuana, opiates, sedative-hypnotics)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Used to rule out causes
  - CBC, CMP
  - Thyroid-stimulating hormone
  - Vitamin B$_{12}$ level
- Select patients
  - HIV, rapid plasma reagin (RPR)
  - Erythrocyte sedimentation rate (ESR)
  - Folate
  - Heavy metal and toxicology screen

Research studies with cerebrospinal fluid (CSF) biomarkers in patient with confirmed AD have shown decreased amyloid beta (1 to 42) and increased $\tau$ and p-$\tau$ levels, which are specific features of AD, and CSF $\tau$ proteins are increased in CJD (3)[A].

Neuroimaging (CT/MRI of brain): cerebral atrophy
- Early age of onset (<65 years), rapid progression, focal neurologic deficits, cerebrovascular disease risk, or atypical symptoms: neuroimaging (MRI/CT) to rule out other causes
  - Important findings
  - AD: diffuse cerebral atrophy starting in association areas, hippocampus, amygdala
  - VaD: old infarcts, including lacunar

Diagnostic Procedures/Other
PET scan not routinely recommended; has been approved to differentiate between Alzheimer disease and frontotemporal dementia
**Test Interpretation**

AD
- NFTs: abnormally phosphorylated τ protein
- Senile plaques: APP derivatives
- Microvascular amyloid

**TREATMENT**

**GENERAL MEASURES**
- Daily schedules and written directions
- Emphasis on nutrition, personal hygiene, accident-proofing the home, safety issues, sleep hygiene, and supervision
- Socialization (adult daycare)
- Sensory stimulation (display of clocks and calendars) in the early to middle stages
- Discussion with the family concerning support and advance directives

**MEDICATION**

- Cognitive dysfunction
  - Medications for AD (4)[A] show a small improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant.
  - Cognitive dysfunction, mild
    - Cholinesterase inhibitors: donepezil (Aricept), 5 to 10 mg/day; rivastigmine (Exelon), 1.5 to 6.0 mg BID, transdermal system 4.6 mg/24 hr and 9.5 mg/24 hr; galantamine (Razadyne), 4 to 12 mg BID, extended release 8 to 24 mg/day
    - Adverse events: nausea, vomiting, diarrhea, anorexia, nightmares, bradycardia/syncope
    - Galantamine warning: associated with mortality in patients with mild cognitive impairment in clinical trial
    - It is suggested to consider cholinesterase inhibitor for patients with mild to moderate dementia (MMSE 10 to 26).
    - In patients with moderate to advanced dementia (MMSE <17), recommendations are to add memantine (10 mg BID) to a cholinesterase inhibitor or use memantine alone in patients who do not tolerate or benefit from a cholinesterase inhibitor.
    - In patients with severe dementia (MMSE <10), it is suggested continuing memantine. However, in advanced dementia, medications can be discontinued to maximize quality of life and patient comfort.
    - Start drug with lowest acquisition cost; also consider adverse event profile, adherence, medical comorbidity, drug interactions, and dosing profiles.

- Cognitive dysfunction, moderate to severe
  - Cholinesterase inhibitors or
  - Memantine (Namenda), 5 to 20 mg/day
    - Adverse events: dizziness, confusion, headache, constipation or
    - Combination cholinesterase inhibitor and memantine

- Commonly associated conditions
  - Psychosis and agitation/aggressive behavior:
    - Look for precipitating factors (infection, pain, depression, medications).
    - Nonpharmacologic therapies (e.g., behavioral interventions, music therapy) are preferred
as first-line treatment.
- Mood stabilizers (valproic acid, carbamazepine) have been used, although evidence is lacking.
- For moderate/severe symptoms; antipsychotics: Initiate low doses, risperidone 0.25 to 1.00 mg/day; olanzapine 1.25 to 5.00 mg/day; quetiapine 12.5 to 50.0 mg/day; aripiprazole 5 mg/day; ziprasidone 20 mg/day
- Atypical antipsychotic, quetiapine, is often first line due to decreased extrapyramidal side effect.
- Novel antipsychotic, pimavanserin (selective 5-HT2A receptor inverse agonist) has shown to effectively treat Parkinson disease psychosis with minimal risk of worsening motor function associated with other treatment (5)[B].

**ALERT**
Black box warning on antipsychotics due to increased mortality in elderly with dementia

- Depression and insomnia
  - Depression:
    - Selective serotonin reuptake inhibitors (SSRIs): Initiate low doses, citalopram (Celexa) 10 mg/day; escitalopram (Lexapro) 5 mg/day; sertraline (Zoloft) 25 mg/day
    - Adverse events: nausea, vomiting, agitation, parkinsonian effects, sexual dysfunction, hyponatremia
    - Venlafaxine, mirtazapine, and bupropion are also useful.
  - Sleep disturbances:
    - Low-dose antidepressants (e.g., Remeron) have significant sedative properties at 7.5 mg or 15 mg.
    - Trazodone 25 to 100 mg is frequently used because of better side effect profile.
  - Psychosis and agitation/aggressive behavior:
    - Some data for SSRIs
    - Benzodiazepines if agitation with anxiety; in elderly, use PRN.

**Geriatric Considerations**
Initiate pharmacotherapy at low doses and titrate slowly up if necessary.
- Benzodiazepines are potentially inappropriate for older adults, yet their use persists.

**ALERT**
Benzodiazepine use is associated with increased fall risk (6)[A].

- Watch decreased renal function and hepatic metabolism.

**ISSUES FOR REFERRAL**
Neuropsychiatric evaluation particularly helpful in early stages or mild cognitive impairment

**ADDITIONAL THERAPIES**
Behavioral modification
- Socialization, such as adult daycare, to prevent isolation and depression
- Sleep hygiene program as alternative to pharmaceuticals for sleep disturbance
- Scheduled toileting to prevent incontinence

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Vitamin E is no longer recommended due to lack of evidence.
Ginkgo biloba is not recommended due to lack of evidence.
NSAIDs, selegiline, and estrogen lack efficacy and safety data.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Worsening physical health issues
- Psychiatry admission may be required because of safety concerns (self-harm/harm to others), self-neglect, aggressive behaviors, or other behavioral issues.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Progression of cognitive impairment by use of standardized tool (e.g., MMSE, ADAS-Cog)
- Development of behavioral problems: sleep, depression, psychosis
- Adverse events of pharmacotherapy
- Nutritional status
- Caregiver evaluation of stress

PATIENT EDUCATION
- Discuss safety, management of finances, medical decision making, possible placement; legal guardianship, if necessary
- Advance directives
- National Institute on Aging: http://www.nia.nih.gov/alzheimers/topics/other-dementias

PROGNOSIS
- AD: usually steady progression leading to profound cognitive impairment:
  - Average survival of AD is about 10 years.
- VaD: incrementally worsening dementia, but cognitive improvement is unlikely
- Secondary dementias: Treatment of the underlying condition may lead to improvement; commonly seen with normal pressure hydrocephalus, hypothyroidism, and brain tumors

COMPLICATIONS
- Wandering
- Delirium
- Sundowner syndrome is common in older people (who are sedated) and also in people who have dementia (adverse reaction to small dose of psychoactive substances).
- Falls with injury
  - Hip fracture
  - Head trauma/hematomas
- Neglect and abuse
- Caregiver burnout

Algorithm: Dementia

CODES
ICD10
- F03 Unspecified dementia
- G30.9 Alzheimer’s disease, unspecified
- F01.50 Vascular dementia without behavioral disturbance

CLINICAL PEARLS
- Medications for AD show a small, statistically significant improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant.
- Do not forget the role of adult protective services in case of elder abuse—elder abuse hotline: 800-922-2275.
- A particular concern in nursing homes relates to the use of physical restraints and antipsychotic medication, which are regulated by Omnibus Budget Reconciliation Act of 1987.
DEMENTIA, VASCULAR
Birju B. Patel, MD, FACP, AGSF • N. Wilson Holland, MD, FACP

BASICS
Vascular dementia is a heterogeneous disorder caused by the sequelae of cerebrovascular disease that manifests in cognitive impairment affecting memory, thinking, language, behavior, judgment, and executive dysfunction.

DESCRIPTION
- Vascular dementia (previously known as multi-infarct dementia) was first mentioned by Thomas Willis in 1672. Later, it was further described in the late 19th century by Binswanger and Alzheimer as a separate entity from dementia paralytica caused by neurosyphilis. This concept has evolved tremendously since the advent of neuroimaging modalities.
- Synonym(s): vascular cognitive impairment (VCI); vascular cognitive disorder (VCD); arteriosclerotic dementia; poststroke dementia; Binswanger disease. Diagnostic and Statistical Manual of Mental Disorders (DSM-5) categorizes vascular dementia as mild or major VCD.

EPIDEMIOLOGY
Second-most common cause of dementia after Alzheimer dementia in the elderly and it frequently overlaps with Alzheimer.

Incidence
About 6 to 12 cases per 1,000/person age >70 years
- Incidence of vascular dementia is declining in high-income countries in the past several decades likely due to better management of vascular risks.

Prevalence
- ~1.2–4.2% in those age >65 years
- 14–32% prevalence of dementia after a stroke

ETIOLOGY AND PATHOPHYSIOLOGY
On autopsy of those with dementia, many have significant vascular pathology that is present, but this is not necessarily correlated clinically with vascular dementia. No set pathologic criteria exist for the diagnosis of vascular dementia such as those that exist for Alzheimer dementia. Pathology includes the following:
- Large vessel disease: cognitive impairment that follows a stroke
- Small vessel disease: includes white matter changes (leukoaraiosis), subcortical infarcts, and incomplete infarction. This is usually the most common cause of multi-infarct dementia.
- Subcortical ischemic vascular disease: due to small vessel involvement within cerebral white matter, brainstem, and basal ganglia. Lacunar infarcts and deep white matter changes are typically included in this category.
- Noninfarct ischemic changes and atrophy
- Transient ischemic attack (TIA)/stroke
- Vascular, demographic, genetic factors
- Vascular disease (i.e., hypertension [HTN], peripheral vascular disease [PVD], atrial fibrillation, hyperlipidemia, diabetes) (1)(B),(2)(C)
Genetics
- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is caused by a mutation in the NOTCH3 gene on chromosome 19 that results in leukoencephalopathy and subcortical infarcts. This is clinically manifested in recurrent strokes, migraine with aura, and vascular dementia.
- Apolipoprotein E gene type: Those with ApoE4 subtypes are at higher risk of developing both vascular and Alzheimer dementia.
- Amyloid precursor protein (APP) gene: leads to a form of vascular dementia called heritable cerebral hemorrhage with amyloidosis

RISK FACTORS
- Age
- Previous stroke
- Smoking
- Diabetes (especially with frequent hypoglycemia)
- HTN
- Atrial fibrillation
- PVD
- Hyperlipidemia
- Metabolic syndrome
- Coronary atherosclerotic heart disease
- Previous myocardial infarction

GENERAL PREVENTION
- Optimization and aggressive treatment of vascular risk factors, such as HTN, diabetes, and hyperlipidemia
- HTN is the single most modifiable risk factor and treatment for it must be optimized.
- Smoking is associated with white matter changes on imaging, which may be associated with small vessel disease and vascular dementia progression.
- Lifestyle modification: weight loss, physical activity, smoking cessation
- Medication management for vascular risk reduction: aspirin usage, statin therapy for hyperlipidemia, antihypertensive therapy

COMMONLY ASSOCIATED CONDITIONS
- CADASIL
- Cerebral amyloid angiopathy (CAA) causes ischemic white matter damage due to amyloid deposition in penetrating cortical vessels.

DIAGNOSIS
Differentiation between Alzheimer dementia and vascular dementia can be difficult, and significant overlap is seen in the clinical presentation of these two dementias. The diagnosis of vascular dementia is a clinical diagnosis. Memory impairment is less prominent in vascular dementia vs. Alzheimer dementia. The neuropsychological pattern observed in vascular dementia is impaired recall, relatively intact recognition, less severe forgetfulness with greater benefit from cues, and more executive dysfunction.
HISTORY
- Gradual, stepwise progression is typical.
- Ask about onset and progression of cognitive impairment and the specific cognitive domains involved.
- Ask about vascular risk factors and previous attempts to control these risk factors.
- Ask about medication compliance.
- Ask about urinary incontinence and gait disturbances. Abnormal gait and falls are strong predictors of development of vascular dementia, particularly unsteady, frontal, and hemiparetic types of gait.
- Look for early symptoms, including difficulty performing cognitive tasks, memory, mood, and assessment of instrumental activities of daily living (IADLs).
- History may include TIAs, cerebrovascular accidents (CVAs), coronary atherosclerotic heart disease, atrial fibrillation, hyperlipidemia, and/or PVD. Small vessel disease usually presents with executive dysfunction. Large vessel disease usually presents with visuospatial and language dysfunction.

PHYSICAL EXAM
- Screen for HTN. Average daily BP and not office BP is associated with progression of cerebrovascular disease and cognitive decline in the elderly.
- Focal neurologic deficits may be present.
- Gait assessment is important, especially looking at gait initiation, gait speed, and balance (5,6).
- Check for carotid bruits as well as abdominal bruits and assess for presence of PVD.
- Check body mass index and waist circumference.
- Do a thorough cardiac evaluation that includes looking for arrhythmias (i.e., atrial fibrillation).

DIFFERENTIAL DIAGNOSIS
- Alzheimer dementia
- Depression
- Drug intoxication
- Central nervous system tumors
- Hypothyroidism
- Vitamin B₁₂ deficiency

DIAGNOSTIC TESTS & INTERPRETATION
- Cognitive testing, such as Saint Louis University Mental Status (SLUMS) and Montreal Cognitive Assessment (MoCA), provides more definitive information in terms of cognitive deficits, especially executive function, which may be lost earlier in vascular dementia. The Mini-Mental State Examination is not sensitive in distinguishing Alzheimer dementia from vascular dementia because it does not have good measures of executive function.
- Neuropsychological testing may also be beneficial, especially in evaluating multiple cognitive domains and their specific involvements and deficits.

Initial Tests (lab, imaging)
As appropriate, consider CBC, comprehensive metabolic profile, lipid panel, thyroid function, hemoglobin A1C, and vitamin B₁₂.
- Imaging is used in conjunction with history and physical examination to support a clinical diagnosis of vascular dementia.
Cognitive deficits observed clinically do not always have to correlate with findings found on neuroimaging studies. MRI is best in terms of evaluation of subtle subcortical deficits. White matter changes and specific location of these changes can be associated with executive dysfunction and episodic memory impairment.

**TREATMENT**
Prevention is the real key to treatment:
- Control of risk factors, including HTN, hyperlipidemia, and diabetes
- Avoidance of tobacco and smoking cessation
- Healthy, low-cholesterol diet

**MEDICATION**
- Clinical evidence for use of acetylcholinesterase inhibitors and memantine reveals limited benefit in vascular dementia but may slow cognitive decline in patients with mixed Alzheimer and vascular dementia (7)[B].
- Controlling BP with any antihypertensive medications, treatment of dyslipidemia (e.g., statins), and treatment of diabetes are very important.
- Selective serotonin reuptake inhibitors (SSRIs) may be of benefit for agitation and psychosis in vascular dementia.

**ADDITIONAL THERAPIES**
- Limit alcohol drink intake to ≤1/day in women and 2/day in men.
- Heavy sustained alcohol use contributes to HTN.
- Preventing new CVAs is key in managing vascular dementia; aspirin and other antiplatelet agents such as clopidogrel may be useful if no contraindications.

**SURGERY/OTHER PROCEDURES**
Patients with symptomatic carotid artery stenosis should be referred to a vascular surgeon to be evaluated for carotid endarterectomy. Carotid endarterectomy is recommended over carotid artery stenting in patients >70 years of age if perioperative morbidity/mortality are <6%.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Ginkgo biloba should be avoided due to increased risk of bleeding, especially in CAA.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Remain sensitive to functional assessment and avoidance of pressure ulcers after CVAs.
- Avoid Foley catheter usage unless necessary due to increased risk of infection.
- Nonpharmacologic approaches to behavior management should be attempted prior to medication usage.
- Providing optimal sensory input to patients with cognitive impairment is important during hospitalizations to avoid delirium and confusion. Patients should be given frequent cues to keep them oriented to place and time. They should be informed of any changes in the daily schedule of activities and evaluations. Family and caregivers should be encouraged to be with patients with dementia as much as possible to further help them from becoming confused during hospitalization. Recreational, physical, occupational, and music therapy can be
beneficial during hospitalization in avoiding delirium and preventing functional decline.

- Emphasis must be placed on screening for, and optimizing, the mood of the patient.
- Depression is very common in older patients, especially those who have had strokes and have become hospitalized. Depression can present as “pseudodementia” with worsening confusion during hospitalization and is a treatable condition.

**ONGOING CARE**

Vascular dementia is a condition that should be followed with multiple visits in the office setting with goals of optimizing cardiovascular risk profiles for patients. Future planning and advanced directives should be addressed early. Family and caregiver evaluation and burden should also be evaluated.

**FOLLOW-UP RECOMMENDATIONS**

Perform regular follow-up with a primary care provider or geriatrician for risk factor modification and education on importance of regular physical and mental exercises as tolerated.

**Patient Monitoring**

Appropriate evaluation and diagnosis of this condition, need for future planning, optimizing vascular risk factors, lifestyle modification counseling, therapeutic interventions

**DIET**

- The American Heart Association diet and Dietary Approaches to Stop Hypertension (DASH) diet is recommended for optimal BP and cardiovascular risk factor control.
- Low-fat, decreased concentrated sweets and carbohydrates, especially in those with metabolic syndrome

**PATIENT EDUCATION**

- Lifestyle modification is important in vascular risk reduction (smoking cessation, exercise counseling, dietary counseling, weight-loss counseling).
- Optimizing vascular risk factors via medications (i.e., HTN, diabetes, atrial fibrillation, PVD, heart disease)
- Avoiding smoking, including secondhand smoke
- Home BP monitoring and glucometer testing of blood sugars if HTN, impaired glucose tolerance, and/or diabetes is present

**PROGNOSIS**

- Lost cognitive abilities that persist after initial recovery of deficits from stroke do not usually return. Some individuals can have intermittent periods of self-reported improvement in cognitive function.
- Risk factors for progression of cognitive and functional impairment poststroke include age, prestroke cognitive abilities, depression, polypharmacy, and decreased cerebral perfusion during acute stroke.

**COMPLICATIONS**

- Physical disability from stroke
- Severe cognitive impairment
- Death
REFERENCES

Alzheimer Disease; Depression; Mild Cognitive Impairment

CODES

ICD10
- F01.50 Vascular dementia without behavioral disturbance
- F01.51 Vascular dementia with behavioral disturbance

CLINICAL PEARLS

- Executive dysfunction and gait abnormalities are often seen early and are more pronounced in vascular dementia as opposed to Alzheimer dementia.
- Memory is relatively preserved in vascular dementia when compared with Alzheimer dementia in the early stages of this disease.
- Stepwise progression, as opposed to progressive decline in Alzheimer dementia, is typical.
- Considerable overlap exists between vascular dementia and Alzheimer dementia in clinical practice, and classification into one of these categories is often difficult. Patients can have mixed etiologies as well.
BASICS

DESCRIPTION
- Pain ± swelling in the head and neck region with origin of infection from the teeth and/or supporting structures (odontogenic); if left untreated, can lead to serious and potentially life-threatening illnesses
- Assume any head and neck infection or swelling to be odontogenic in origin until proven otherwise.
- System(s) affected: oropharynx, throat, dental, gastrointestinal
- Synonym(s): odontogenic infections, dental abscess

EPIDEMIOLOGY
- More than 90% of all head and neck infections have odontogenic origins
- 18% of 5 to 19 year olds have untreated dental caries.
- 28% of individuals age >20 years have untreated dental caries (1).
- Rates are higher in Hispanic (21.7%) and black (23%) children/teens (1)[A].
- 92% of adults 20 to 64 years have had dental caries.
- 25% of children age 5 to 17 years account for 80% of caries in the United States.
- 17% of adults age >64 years are edentulous (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Dental caries is the most common worldwide chronic disease.
- Caries or trauma can lead to death of the tooth pulp, which can lead to infection and/or abscess of adjacent tissues via direct or hematogenous bacterial colonization.
- Caries (tooth decay; “cavity”) represent a contagious bacterial infection causing demineralization and destruction of the tooth tissue (enamel, dentin, and cementum).
- Streptococcus mutans is transmitted to newly dentate infants by caregivers.
- Acidic secretions from S. mutans are implicated in early caries.
- Often there is polymicrobial mix of anaerobes in dental abscess (viridans streptococci and Streptococcus anginosus).
- Anaerobes, including peptostreptococci, Bacteroides, Prevotella, and Fusobacterium, have also been implicated; lactobacilli not seen in healthy subjects but common in patients with extensive caries (2)
- Preventable with good oral hygiene, low-cariogenic diet, access to fluoride, and professional dental care
- Fluoride has dramatically decreased dental caries.

RISK FACTORS
- Low socioeconomic status
- Parent and/or sibling with history of caries or existing untreated dental caries (especially in past 12 months)
- Previous dental caries
- Poor access to dental/health care; lack of dental insurance
Fear of dentist
Poor oral hygiene
Poor nutrition, including diet containing high level of sugary foods and drinks
Trauma to the teeth or jaw
Inadequate access to and use of fluoride
Gingival recession (increased risk of root caries)
Physical and mental disabilities
Decreased salivary flow (e.g., use of anticholinergic medications, immunologic diseases, radiation therapy to head and neck)

GENERAL PREVENTION
Most dental problems can be avoided through flossing/use of interdental brushes; brushing with fluoride toothpaste, systemic fluoride (fluoridated bottled water; fluoride supplements for high-risk patients and in nonfluoridated areas); fluoride varnish for moderate- to high-risk patients and all children age <6 years; regular dental cleanings (1)(3)
Prevent transmission of S. mutans from mother/caregiver to infant by improving maternal dentition, chlorhexidine gluconate rinses, and use of xylitol products for mother especially during first 2 years of a child’s life. Avoid smoking, which is linked to severe periodontal disease (2).
Good control of systemic diseases (e.g., diabetes)
Fluoride varnish provided by dental or medical primary care providers twice per year (2,3)

COMMONLY ASSOCIATED CONDITIONS
Extensive caries, crowding, multiple missing teeth
Periapical and periodontal abscess
Soft tissue cellulitis
Periodontitis (deep inflammation ± infection of gingiva, alveolar bone support, and ligaments)

DIAGNOSIS

HISTORY
Pain of involved tooth; can be referred to ears, jaw, cheek, neck, or sinuses; unexplained headaches
Hot/cold sensitivity
Pain can be unprovoked, intermittent, and/or constant.
Pain with biting or chewing
Trismus (inability to open mouth)
Bleeding or purulent drainage from gingival tissues
When severe infection (systemic)
    – Fever
    – Difficulty breathing or swallowing
    – Raspy voice
    – Mental status changes
Evaluate children <4 years with stiff neck, sore throat, and dysphagia for retropharyngeal abscess.

PHYSICAL EXAM
Gingival edema and erythema
Cheek (extraoral) or vestibular (intraoral) swelling
Fluctuant mass at involved site
Suppuration of gingival margin
Submandibular or cervical lymphadenopathy
Severe (systemic) infection may present with dysphagia, fever, and signs of airway compromise.

DIFFERENTIAL DIAGNOSIS
- Bacterial or viral pharyngitis
- Pericoronitis (inflammation ± infection of gum flap over mandibular last molar, typically 3rd molars)
- Otitis media or externa
- Sinusitis
- Headache/migraine
- Viral (HSV1, herpangina, hand-foot-mouth disease) or aphthous stomatitis
- Temporomandibular joint (TMJ) dysfunction (myofascial pain, ± internal derangement of TMJ)
- Parotitis
- Jaw pain can be anginal equivalent, especially in women and especially lower left side of the jaw.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- No initial labs needed, unless patient looks acutely ill.
- If acutely ill
  - Consider complete blood count with differential.
  - If abscess present, aspirate pus and culture for aerobes and anaerobes (4).
  - Typically polymicrobial infections with anaerobic gram-negative rods and anaerobic gram-positive cocci (4)
- Individual films of suspected teeth, including root apices; test with palpation, percussion, and cold sensitivity.
- Panoramic film or CT scan of the teeth and jaw to evaluate the extent of infection

Follow-Up Tests & Special Considerations
- Panoramic radiograph, particularly if trismus present
- CT scan can be helpful if facial swelling extends below inferior border of mandible or into infraorbital space. This helps to locate for potential incision and drainage by oral and maxillofacial surgeon or ear/nose/throat.

TREATMENT
- Isolated pain (no swelling or systemic signs of infection) does not warrant antibiotic use.
- If localized, consider incision and drainage.
- Appropriate pain control: Anti-inflammatory agents are first line; short-course opioids in some cases (5) [A]
- Refer to oral health provider for definitive treatment: root canal, extraction, gum therapy (4).
● If infection is severe (systemic symptoms), consider hospitalization with IV antibiotics until stable. May need intraoral or extraoral incision and drainage; definitive treatment (extraction or root canal therapy) necessary to prevent progression or recurrence

GENERAL MEASURES
● Ibuprofen 600 to 800 mg (pediatrics: 10 mg/kg) q6h or acetaminophen 650 to 1,000 mg (pediatrics: 10 to 15 mg/kg) q4–6h PRN for pain
● For more severe pain, consider acetaminophen with ibuprofen (synergistic effect) + short course of opioids.
● Local nerve block with long-acting anesthetic (bupivacaine); avoid penetrating infection to avoid tracking infection.

MEDICATION

First Line
● Amoxicillin: 500 mg TID for 7 to 10 days; in children, 40 to 60 mg/kg/day divided TID
● If penicillin allergic, use clindamycin 300 mg PO TID for 7 days.

Second Line
If long-standing infection or no response to first-line treatment
● Clindamycin: 300 mg PO TID for 7 to 10 days
● Amoxicillin/clavulanic acid (500 mg/125 mg), 1 tablet PO TID for 7 days
● If severe infection, consider IV antibiotics (ampicillin-sulbactam, cefoxitin, cefotetan).
● Consider double coverage with metronidazole 500 mg PO TID for 7 days for better bone penetration and good anaerobic coverage. Do not use metronidazole alone; will increase development of resistant strains; can be used with amoxicillin or clindamycin

ISSUES FOR REFERRAL
Consult an oral health provider, and ensure definitive follow-up.

SURGERY/OTHER PROCEDURES
● Incise and drain large, fluctuant abscesses.
● Root canal or extraction is definitive treatment.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Criteria for hospital admission: swelling involving deep spaces of the neck, floor of the mouth, or infraorbital region; deviation of the airway; unstable vital signs; fever (>101°F); chills; raspy voice; confusion or delirium; or evidence of invasive infection or cellulitis
● Ensure secure airway.
● IV fluid resuscitation if necessary
● Ensure good oral hygiene.
● Rinse or swab mouth with chlorhexidine gluconate BID.
● Use warm saltwater rinses several times per day, especially after incision and drainage; ice packs to decrease swelling and encourage drainage
● Discharge patient when
  – Airway not compromised
  – Abscess and sepsis eliminated
  – Able to take PO intake and ambulate
ONGOING CARE

Educate regarding proper oral hygiene, need for follow-up dental care, and potential medical complications that arise due to lack of dental care.

FOLLOW-UP RECOMMENDATIONS

- Follow up with oral health provider within 24 hours.
- Ensure adequate PO intake, including protein.

DIET

- Maintain a healthy diet; bacteria thrive on refined sugar and starch.
- Avoid sugary foods that stick between the teeth.
- Avoid the use of sugary/carbonated drinks throughout day; water as beverage of choice between meals

Pediatric Considerations

In children, limit the frequency of sugary drinks and advise against sleeping with a bottle; fluoride varnish twice a year (more for higher risk children) for children age <6 years (3)

PATIENT EDUCATION

- Control caries and periodontal disease.
- Biannual dental visits at a minimum
  - Limit the frequency of sugar/carbonated drinks and sugary or sticky foods.
- In young children, avoid sleeping with a bottle to decrease the chance of dental caries.
- Brush twice daily and use floss/interdental brush daily.

PROGNOSIS

Prognosis is excellent with proper treatment.

COMPLICATIONS

- Ludwig angina
- Retropharyngeal and mediastinal infection
- Osteomyelitis
- Endocarditis/cardiac tamponade
- Submental infection
- Submandibular infection
- Can cause unstable diabetes in diabetics/worsen preexisting heart disease
- Brain abscess/death

REFERENCES

ADDITIONAL READING

CODES

ICD10

- K02.9 Dental caries, unspecified
- K04.7 Periapical abscess without sinus
- K12.2 Cellulitis and abscess of mouth

CLINICAL PEARLS

- Do not ignore tooth pain.
- Treat patients with facial swelling aggressively because infections can spread quickly, leading to significant morbidity or even death.
- Prevention (oral hygiene, fluoride, dental visits) is the key to avoiding odontogenic infections.
DEPRESSION
Grant M. Reed, DO ● Johan Sosa De La Cruz, MD

BASICS

DESCRIPTION
A primary mood disorder characterized by a sustained feeling of sadness and/or decreased interest in all or most activities once enjoyed (anhedonia), which represents a change from previous functioning

EPIDEMIOLOGY

Incidence
- In the U.S., 8.1% of adults age ≥20 years experienced depression in a given 2-week period between 2013 and 2016.
- 19.2% lifetime risk of having MDD

Prevalence
- Non-Hispanic Asian adults had the lowest prevalence of depression (3.1%) compared with Hispanic (8.2%), non-Hispanic white (7.9%), and non-Hispanic black (9.2%) adults. This pattern was observed among both men and women.
- Among all race and Hispanic-origin groups (except non-Hispanic Asian), men had a significantly lower prevalence of depression compared with women.
- Prevalence decreases with increasing levels of family income for both men and women.
- Predominant age: low risk before early teens but highest prevalence in teens and young adults.

ETIOLOGY AND PATHOPHYSIOLOGY
There are diverse theories regarding the pathophysiology; none proven

Genetics
Multiple gene loci place a person at increased risk when faced with environmental stressor; twin studies suggest 37% concordance.

RISK FACTORS
- Female > male (2:1)
- Severity of first episode
- Persistent sleep disturbances
- Presence of chronic disease(s), recent myocardial infarction (MI), cardiovascular accident (CVA)
- Strong family history (depression, bipolar, suicide, substance abuse), spouse with depression
- Childhood trauma/maltreatment
- Substance abuse and dependence, domestic abuse/violence
- Losses, stressors, unemployment
- Single, divorced, or unhappily married

COMMONLY ASSOCIATED CONDITIONS
- Bipolar disorder, cyclothymic disorder, grief reaction, anxiety disorders, somatoform disorders, schizophrenia/schizoaffective disorders
Medical comorbidity
Substance abuse

**DIAGNOSIS**

DSM-5 requires the following criteria for Major Depressive Disorder:

- **Criterion A:** ≥5 of the following symptoms present nearly every day during the same 2-week period, with at least 1 of the 5 being either depressed mood or loss of interest or pleasure:
  - Depressed mood most of the day by subjective report or observation from other people
  - Markedly diminished interest or pleasure in all activities most of the day by subjective report or observation from other people
  - Decreased or increased appetite or significant weight loss without dieting or weight gain
  - Insomnia or hypersomnia
  - Fatigue or energy loss
  - Agitation, restlessness, or slowed speech or body movements observable by others
  - Worthlessness, excessive/inappropriate guilty feelings
  - Diminished thinking/concentration, poor memory, indecisiveness
  - Recurrent thoughts of death, suicidal ideations, or suicide attempt or a specific plan for committing suicide

- **Criterion B:** Symptoms cause significant social, occupational, or functional distress or impairment.

- **Criterion C:** Symptoms not attributable to substance effects or other medical conditions

**HISTORY**

The mnemonic “SIGECAPS” is helpful.

- **Sleep:** changes in sleep habits from baseline, including excessive sleep, early waking, or inability to fall asleep
- **Interest:** loss of interest in previously enjoyable activities (anhedonia)
- **Guilt:** excessive or inappropriate guilt that may or may not be related to a specific problem or circumstance
- **Energy:** perceived lack of energy
- **Concentration:** inability to concentrate on specific tasks
- **Appetite:** an increase or decrease in appetite
- **Psychomotor:** restlessness and agitation or the perception that everyday activities are too strenuous to manage
- **Suicidality:** the desire to end one’s life or hurt oneself, harmful thoughts directed internally, or recurrent thoughts of death or homicidality

**Geriatric Considerations**

- Often difficult to diagnose due to medical comorbidities
- Can present as memory difficulties
- Geriatric Depression Scale (GDS 15) improves rate of diagnosis in primary care setting.

**Pediatric Considerations**

Can present with somatic symptoms (headaches, GI upset), irritability or anger, concentration difficulties in school, frequent absences from school, or a change in grades
PHYSICAL EXAM
A comprehensive physical and mental status examination
- Level of consciousness and orientation
- Appearance: hygiene, posture, clothing
- Attitude: hostility, apathy
- Behavior: eye contact, psychomotor agitation or retardation
- Mood: depressed, anxious, angry, elated, tearful, etc.
- Affect: mood-congruent, flat, labile, manic, etc.
- Memory: intact immediate, recent, and remote
- Speech: fluency, repetition, comprehension
- Thought processes/content: presence of delusions, hallucinations, suicidal/homicidal thoughts, flight of ideas or tangentiality, grandiosity, obsessions/compulsions
- Insight: understanding of own illness
- Judgment: capacity to make rational decisions

DIFFERENTIAL DIAGNOSIS
- Mental health conditions:
  - Depressed phase of bipolar disorder—inquire if prior mania, family or personal history of bipolar disorder, prior agitation, or excitement with antidepressant medication.
  - Adjustment disorder with depressed mood
  - Substance abuse-related mood disorders
- Medical comorbidity: adrenal diseases, hypothyroidism, diabetes, hypercalcemia, liver or renal failure, malignancy, sleep disorders, chronic fatigue syndrome, fibromyalgia, lupus
- Neurologic or cognitive disorders such as neurodegenerative CNS disease, dementia, or delirium
- Deficiencies: vitamin B3, vitamin B12, or folate

DIAGNOSTIC TESTS & INTERPRETATION
- The Patient Health Questionnaire-9 (PHQ-9) is a brief screening test valid for diagnosis of MDD in primary care settings. A score of 10 or higher indicates that depression is likely present.
- Other validated scales include Beck Depression Inventory, Zung, or GDS 15

Initial Tests (lab, imaging)
To rule out medical causes
- CMP to evaluate kidney and liver function
- TSH
- CBC

Follow-Up Tests & Special Considerations
Consider urine drug screen if symptoms suggest intoxication or concerning historical.

TREATMENT
American Psychiatric Association (APA) 2010 treatment guideline recommend the following (1)
- Acute Phase (first 3 months of treatment)
– Full evaluation, including risk to self and others, with selection of appropriate treatment setting. Goal should be symptom remission.
  o For mild to moderate depression, either psychotherapy and/or medication is appropriate.
  o For refractory or severe depression, both medication and psychotherapy is preferred.
  o Hospitalization is indicated for those at risk of harm to self or others, if the patient is incapacitated so as to be unable to take care of themselves, or if there is no support system to assist with treatment.
– See within 2–4 weeks of starting medication and q2wk until improvement, then monthly.
– Continue to increase dosage q3–4wk until remission. Full medication effect is achieved in 4–6 weeks. Augmentation with a second medication may be necessary.
– ≥6 visits recommended for monitoring (younger patients, those at high suicide risk, see within 1st week, and follow frequently).

○ Continuation Phase (4–9 months of treatment)/Maintenance Phase (9+ months of treatment)/Monitor for relapse; q3–6mo if stable
  – Use depression rating scales and patient reports to monitor response.
  – For patients not responding to medication alone, psychotherapy should be added.
  – Once remission achieved, dosage should be continued for at least 6 to 9 months to reduce relapse; CBT is also effective in reducing relapse (visits typically q2wk).
  – Medications should be tapered gradually (weeks to months) to allow for the detection of recurring symptoms and to minimize discontinuation syndromes.

GENERAL MEASURES
Psychotherapy
○ Cognitive-Behavioral Therapy (CBT): Combines cognitive psychotherapy with behavioral therapy. Proven effective (NNT = 2.75)
○ Interpersonal Psychotherapy (IPT): Identifies a trigger of the depressive episode, facilitates mourning, promotes recognition of affects, resolves role disputes and role transitions, and builds social skills.
○ Psychodynamic Psychotherapy: used to identify unconscious thoughts leading to current behavior
○ Family and Marital Therapy: Addresses family or relationship-oriented problems
○ Problem Solving Therapy: Combines elements of CBT and IPT into a brief treatment lasting 6–12 sessions. May have a role in those with mild symptoms of depression.
○ Supportive Psychotherapy: Improves self-esteem, psychological functioning, and adaptive skills by focusing on current, problematic relationships or maladaptive patterns of behavior and/or emotional responses.
○ For the initial treatment of unipolar major depression, consider either psychotherapy alone or in combination with medications.

MEDICATION
Start at lowest available dose and maintain highest effectively tolerated FDA-approved dose for at least 4–6 weeks before deeming ineffective. Effectiveness is comparable between and within drug classes; selection should be based on provider familiarity and patient characteristics/preferences such as:
○ Safety and side effect profile
○ Comorbid illnesses and concurrent medications
○ Specific depressive symptoms
 Ease of use (frequency of dosing) or cost
 Patient preference

**First Line**
Selective Serotonin Reuptake Inhibitors (SSRIs) (brand name): starting dose; usual dose [special notes]
- Citalopram (Celexa): 20 mg/day; 20–40 mg/day [FDA warning: doses >40 mg/day risk of QTc prolongation]
- Escitalopram (Lexapro): 10 mg/day; 10–20 mg/day [causes dose-dependent QTc prolongation]
- Fluoxetine (Prozac): 20 mg/day; 20–40 mg/day [FDA approved for teens]
- Fluvoxamine (Luvox): 50 mg qhs; 50–200 mg/day [off label for depression; primarily used for OCD]
- Paroxetine (Paxil): 20 mg/day or 25 mg CR/day; 20–40 mg/day or 50–62.5 mg CR/day
- Sertraline (Zoloft): 50 mg/day; 50–200 mg/day

Common adverse effects: sexual dysfunction (20%), nausea, GI upset, dizziness, insomnia, headache, weight gain. Adverse effects typically resolve within the 1st week.
- Abrupt discontinuation may cause withdrawal symptoms (i.e., dizziness, nausea, headache, paresthesia).

**Pregnancy Considerations**
- SSRIs (most are Pregnancy Category C): fluoxetine, sertraline, and bupropion are widely used and considered safe. After 20 weeks’ gestation there is an increased risk of pulmonary HTN; mild transient neonatal syndrome of CNS; and motor, respiratory, and GI signs.
- Paroxetine (Pregnancy Category D): There is conflicting evidence regarding the risk of congenital cardiac defects and other congenital anomalies in the 1st trimester.
- Newborns of mothers on antidepressants may exhibit a brief period of withdrawal symptoms.

**Pediatric Considerations**
See “Depression, Pediatric” topic.

**Second Line**
- Tricyclic and Tetracyclic Antidepressants (TCAs)
  - Amitriptyline** (Elavil): 25–50 mg qhs; 100 to 300 mg/day [serotonin > norepinephrine reuptake inhibitor]
  - Amoxapine (Asendin): 25 mg qhs or TID; 200–300 mg/day [norepinephrine > serotonin reuptake inhibitor]
  - Clomipramine** (Anafranil): 25 mg qhs or TID; 100–250 mg/day [serotonin > norepinephrine reuptake inhibitor]
  - Desipramine** (Norpramin): 25 mg/day; 150–300 mg/day [may be sedating for some, activating for others]
  - Doxepin** (Sinequan): 25 mg qhs up to 150 mg/day; 150–300 mg/day [highly sedating and causes weight gain]
  - Imipramine** (Tofranil): 25 mg qhs or 150 mg/day; 150–300 mg/day [serotonin > norepinephrine reuptake inhibitor]
  - Maprotiline** (Ludiomil): 25 mg qhs; 100–225 mg qhs [potent norepinephrine reuptake inhibitor]
  - Nortriptyline (Pamelor): 25 mg qhs; 50–150 mg/day [norepinephrine > serotonin reuptake inhibitor]
– Protriptyline (Vivactil): 10 mg qhs up to 10 mg TID; 15–60 mg qhs [better tolerated due to low affinity for H1/M1 receptors]
– Trimipramine** (Surmontil): 25 mg qhs; 150–300 mg/day [serotonin reuptake inhibitor]
– **Drugs are highly sedating and associated with weight gain.

Similar efficacy to SSRIs, however, therapy is limited by adverse effects (1)[C].
– Avoid use when these comorbidities are present: arrhythmias and other significant cardiac disease, seizure disorders, osteoporosis, glaucoma.
– Common adverse effects: orthostatic hypotension, dry mouth, blurred vision, constipation, urinary retention, tachycardia, confusion/delirium.

Serotonin Modulators
– Nefazodone (Serzone): 100 mg BID; 300–600 mg/day [not commonly used because of risk of liver failure]
– Trazodone (Desyrel / Trialodine): 50 mg BID; 200–400
– Vilazodone (Viibryd): 10 mg qhs titrated to 20 mg qhs in week 2; 20–40 mg/day [take with food]
– Vortioxetine (Trintellix): 5–10 mg/day; 20 mg/day
– Common adverse effects: somnolence, dizziness, constipation or diarrhea, sexual dysfunction

Monoamine Oxidase Inhibitors (MAOIs)
– Phenelzine (Nardil): 15 mg/day titrated to 15 mg TID over 2–3 days; 60–90 mg/day
– Selegiline (Eldepryl): 6 mg/24 hr; 6–12 mg/24 hr
– Tranylcypromine (Parnate): 10 mg/day; 30–60 mg/day
– Common adverse effects: hypotension, sexual dysfunction, sleep disturbance.

** Black box warning: Increased risk of suicidality in children, adolescents, and young adults up to age 25 years who are treated with antidepressants. Although this has not been extended to adults, suicide risk assessments are warranted for all patients.

– Serotonin syndrome: a rare but potentially lethal complication from rapid increase in dose or new addition of medication with serotonergic effects

– Antidepressants can precipitate manic episodes in those with bipolar disorder. Use with caution if a personal or family history.

– TCAs can be fatal in overdose.
– Allow 14-day period off of all antidepressants before starting MAOIs.

ISSUES FOR REFERRAL
Refer immediately if presence of active suicidal plan or intent, severe self-neglect, or significant risk of self-harm.

ADDITIONAL THERAPIES
– Electroconvulsive Therapy (ECT) is indicated for severe refractory depression or severe depression with psychotic features or catatonia and those with an urgent need for response (suicidal or nutritionally compromised).
– Repetitive transcranial magnetic stimulation (rTMS) may be helpful for treatment-resistant depression.

SURGERY/OTHER PROCEDURES
Deep Brain Stimulation and Deep Cortical Stimulation are investigational treatments for resistant
depression.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Not regulated by FDA
- Hypericum perforatum (St. John’s wort): 300–1,800 mg/day
- Light therapy: effective for seasonal affective disorder

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients at risk for suicide should be treated as inpatients.

ONGOING CARE

PATIENT EDUCATION
- Depression is a common, treatable medical illness and not a character defect.
- Medications may need to be taken for at least 2–4 weeks before any beneficial effect is noted. It may take 6–8 weeks to reach maximal efficacy.
- Recommend exercise, good sleep, hygiene, nutrition, and decreased use of tobacco and alcohol.
- The National Suicide Prevention Lifeline 800-273-TALK (8255) is a free 24-hour hotline.

PROGNOSIS
- 70% show significant improvement.
- 50% will relapse over their lifetime.

REFERENCES

SEE ALSO
- Depression, Adolescent; Depression, Geriatric; Depression, Pediatric; Depression, Postpartum; Depression, Treatment Resistant; Suicide; Suicide, Pediatric
- Algorithm: Depressive Episode, Major

CODES

ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F34.1 Dysthymic disorder

CLINICAL PEARLS
- Therapeutic alliance is important to treatment success.
- Given the high recurrence rates, long-term treatment is often necessary.
BASICS

DESCRIPTION
- Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) depressive disorders include major depressive disorder (MDD), disruptive mood dysregulation disorder (DMDD), persistent depressive disorder (PDD), premenstrual dysphoric disorder, substance/medication-induced depressive disorder, and other nonspecific depression. This chapter will focus on MDD as it relates to the adolescent patient.
- MDD is a primary mood disorder characterized by sadness and/or irritable mood with impairment of functioning; abnormal psychological development; and a loss of self-worth, energy, and interest in typically pleasurable activities.
- DMDD is characterized by having severe, recurrent outbursts along with persistent irritability and anger.
- PDDr is characterized by a depressed mood for most days lasting at least 1 year in a child/adolescent.
- Adolescents with depression are likely to suffer broad functional impairment across social, academic, family, and occupational domains, along with a high incidence of relapse and a high risk for substance abuse and other psychiatric comorbidity.

EPIDEMIOLOGY

Incidence
During adolescence, the cumulative probability of depression ranges from 5% to 20% (1).

Prevalence
- MDD: 6–12% of adolescents; twice as common in females
- DMDD: 2–5%; more prominent in males (2)

ETIOLOGY AND PATHOPHYSIOLOGY
- Unclear; low levels of neurotransmitters (serotonin, norepinephrine) may produce symptoms; decreased functioning of the dopamine system also contributes.
- External factors may affect neurotransmitters independently.
- Hormonal changes during puberty

Genetics
- Offspring of parents with depression have 3 to 4 times increased rates of depression compared with offspring of parents without mood disorder (1).
- Family studies indicate that anxiety in childhood tends to precede adolescent depression (1).

RISK FACTORS
- Increased 3 to 6 times if first-degree relative has a major affective disorder; 3 to 4 times in offspring of parents with depression
- Prior depressive episodes
History of insomnia, anxiety disorders, attention deficit hyperactivity disorder (ADHD), and/or learning disabilities
- Increased screen time (3)
- Female gender
- Low socioeconomic status
- General stressors: adverse life events, difficulties with peers, loss of a loved one, academic difficulties, abuse, chronic illness, and tobacco abuse

GENERAL PREVENTION
Insufficient evidence for universal depression prevention programs (psychological and social)
- Some evidence indicates that child and adolescent mental health can be improved by successfully treating maternal depression (1)[A].
- The United States Preventive Services Task Force (USPSTF) recommends the screening of adolescents (12 to 18 years of age) for MDD when systems are in place to ensure accurate diagnosis, appropriate treatment, and follow-up.

COMMONLY ASSOCIATED CONDITIONS
- 2/3 of adolescents with depression have at least one comorbid psychiatric disorder.
- 20% meet the criteria for generalized anxiety disorder.
- Also associated with behavioral disorders, substance abuse, eating disorders

DIAGNOSIS
HISTORY
- Adolescents may present with medically unexplained somatic complaints (fatigue, irritability, headache).
- Based on DSM-5 criteria, ≥5 of the following symptoms have been present during the same 2-week period and represent a change from previous functioning: At least one of the symptoms is either depressed mood or loss of interest or pleasure (2):
  - Criterion A
    o Depressed mood most of the day, nearly every day, either subjective report or observation by others (feelings of sadness, emptiness, hopelessness; in children, can be irritability)
    o Markedly diminished interest or pleasure in all activities most of the day, nearly every day
    o Significant weight loss when not dieting or weight gain (>5% body weight in 1 month)
    o Insomnia or hypersomnia
    o Psychomotor agitation or retardation nearly every day
    o Fatigue or loss of energy
    o Feelings of worthlessness or excessive or inappropriate feelings of guilt nearly every day
    o Diminished ability to think or concentrate, or indecisiveness, nearly every day
    o Recurrent thoughts of death, recurrent suicidal ideation or attempt
  - Criterion B: Symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
  - Criterion C: Episode is not attributable to substances’ effects or other medical conditions.
  - Criterion D: Episode is not better explained by a schizoaffective, schizophreniform, or delusional disorder.
  - Criterion E: There has never been a manic or hypomanic episode.
PHYSICAL EXAM
- Psychomotor retardation/agitation may be present.
- Clinicians should carefully assess patients for signs of self-injury (such as wrist lacerations) or abuse.

DIFFERENTIAL DIAGNOSIS
- Normal bereavement
- Substance-induced mood disorder
- Bipolar disorder
- Adjustment disorder with depressed mood
- Mood disorder secondary to a medical condition (thyroid, anemia, vitamin deficiency, diabetes)
- Organic central nervous system diseases
- Malignancy
- Infectious mononucleosis or other viral diseases
- ADHD, posttraumatic stress disorder (PTSD), eating disorders, and anxiety disorders
- Sleep disorder
- Sadness

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
May be used to rule out other diagnoses (i.e., complete blood count, thyroid-stimulating hormone, glucose, mono spot, and urine drug)

Follow-Up Tests & Special Considerations
None with sufficient sensitivity/specificity for diagnosis

Diagnostic Procedures/Other
- Depression is primarily diagnosed after a formal interview, with supporting information from caregivers and teachers.
- Standardized tests are useful as screening tools and to monitor response to treatment but should not be used as the sole basis for diagnosis:
  - Beck Depression Inventory II (BDI-II): ages 13 to 18 years (1)[A]
  - Child Depression Inventory 2 (CDI2): ages 7 to 17 years
  - Center for Epidemiologic Studies Depression Scale for Children (CES-DC): ages 6 to 17 years
  - Patient Health Questionnaire-9 (PHQ-9): ages 13 to 17 years with ideal cut point of 11 or higher (instead of 10 used for adults)
- The USPSTF recommends screening for MDD in adolescents ages 12 to 18 years but states that current evidence is insufficient to assess benefits and harms for screening children aged 11 years or younger (4)[B].
- The evaluation of adolescents who screen positive for depression should include assessment of potential for harm to self and others using structured screening and interview tools (5).
GENERAL MEASURES

- Active support and monitoring with short validated scales should be used in mild cases for 6 to 8 weeks.
- Psychotherapy and/or medication should be considered if active support and monitoring do not improve symptoms (6)[A].
- Treatment should include psychoeducation, supportive management, and family and school involvement (7)[C].
- Initial management should include treatment planning and ensuring that the patient and family are comfortable with the plan (7)[C].
- A Cochrane review showed that there was no significant difference between remission rates for adolescents treated with cognitive-behavioral therapy (CBT) versus medication or combination therapy immediately postintervention (6)[A].
- A multitreatment meta-analysis showed that combined fluoxetine/CBT had higher efficacy than monotherapies, but other selective serotonin reuptake inhibitors (SSRIs), such as sertraline and escitalopram, were better tolerated (7)[A].

MEDICATION

First Line

- Fluoxetine: for depression in age >8 years. Starting dose 10 mg/day; effective dose 10 to 60 mg/day. The most studied SSRI and with the most favorable effectiveness and safety data has the longest half-life of the SSRIs and is not generally associated with withdrawal symptoms between doses or on discontinuation (6)[A].
- Escitalopram: for depression in age >12 years. Starting dose of 5 mg/day; effective dose of 10 to 20 mg/day (6)[A]
- Citalopram: for depression in age >12 years. Starting dose of 10 mg/day; effective dose of 10 to 40 mg/day (6)[A]
- Sertraline: for depression in age >12 years. Starting dose of 25 mg/day; effective dose of 50 to 200 mg/day (6)[A]
- Can titrate dose every 1 to 2 weeks if no significant adverse effects emerge (headaches, GI upset, insomnia, agitation, behavior activation, suicidal thoughts) (6)[A]

ALERT

SSRI black box warning to monitor for worsening condition, behavior changes, and suicidal thoughts (6)[A]

- Antidepressant treatment should be continued for 6 to 12 months at full therapeutic dose after the resolution of symptoms at the same dosage (6)[C].
- Given their rates of increased drug metabolism, adolescents may be at higher risk for withdrawal symptoms from SSRIs than adults; if these are present, twice-daily dosing may be considered (7)[A].
- All other SSRIs except fluoxetine should be slowly tapered when discontinued (6)[A].

Pediatric Considerations

- Tricyclic antidepressants (TCAs) have not been proven to be effective in adolescents and should not be used (6)[A].
- Paroxetine (SSRI): Avoid use due to short half-life, associated withdrawal symptoms, and higher association with suicidal ideation.
ISSUES FOR REFERRAL
- Collaborative care interventions between mental health and primary care have a greater improvement in depressive symptoms after 12 months (6)[B].
- Primary care providers should provide initial treatment of pediatric depression. Refer to a child psychiatrist for severe, recurrent, or treatment-resistant depression or if the patient has comorbidities.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Physical exercise and light therapy may have a mild to moderate effect (8)[B].
- St. John’s wort, acupuncture, S-adenosylmethionine, and 5-hydroxytryptophan have not been shown to have an effect or have inadequate studies to support use in adolescent depression.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
If severely depressed, psychotic, suicidal, or homicidal, one-on-one supervision may be needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- SSRI medications include black box warning to monitor for worsening condition, behavior changes, and suicidal thoughts (6)[A]
- Systematic and regular tracking of goals and outcomes from treatment should be performed, including assessment of depressive symptoms and functioning in home, school, and peer settings (6)[A].
- Diagnosis and initial treatment should be reassessed if no improvement is noted after 6 to 8 weeks of treatment (6)[A].
- The goal of treatment should be sustained symptom remission and restoration of full function.
- Educate patients and family members about the causes, symptoms, course, and treatments of depression, risks of treatments, and risk of no treatment.

PROGNOSIS
- 60–90% of episodes remit within 1 year.
- 50–70% of remissions develop subsequent depressive episodes within 5 years.
- Depression in adolescence predicts mental health disorders in adult life, psychosocial difficulties, and ill health (2)[A].
- Parental depression at baseline significantly affects intervention effects.

COMPLICATIONS
- Treatment-induced mania, aggression, or lack of improvement in symptoms
- School failure/refusal
- 1/3 of adolescents with suicidal ideation go on to make an attempt (7).

REFERENCES

CODES
ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F32.8 Other recurrent depressive disorders

CLINICAL PEARLS
- Adolescent depression is underdiagnosed and often presents with irritability and anhedonia.
- Fluoxetine is the most studied FDA-approved treatment for adolescent depression.
- Escitalopram, citalopram, and sertraline are also FDA-approved antidepressants.
- CBT combined with fluoxetine is efficacious for adolescents with major depression.
- Paroxetine and TCAs should not be used to treat adolescent depression.
- Referral to a child psychiatrist is appropriate for complex cases or treatment-resistant depression.
- Monitor all adolescents with depression for suicidality, especially during the 1st month of treatment with an antidepressant.
DEPRESSION, GERIATRIC
Fozia Akhtar Ali, MD • Nneka I. Okafor, MD, MPH

BASICS

DESCRIPTION
Depression is a primary mood disorder characterized by a depressed mood and/or a markedly decreased interest or pleasure in normally enjoyable activities most of the day, almost every day for at least 2 weeks, and causing significant distress or impairment in daily functioning with at least four other symptoms of depression.

EPIDEMIOLOGY
Prevalence rates among the elderly vary largely depending on the specific diagnostic instruments used and their current health and/or home environment:
- 2–10% of community-dwelling elderly
- 5–10% seen in primary care clinics
- 10–37% of hospitalized elderly patients
- 12–27% of nursing home residents

ETIOLOGY AND PATHOPHYSIOLOGY
- Significant gaps exist in the understanding of the underlying pathophysiology.
- Ongoing research has identified several possible mechanisms, including the following:
  - Monoamine transmission and associated transcriptional and translational activity
  - Epigenetic mechanisms and resilience factors
  - Neurotrophins, neurogenesis, neuroimmune systems, and neuroendocrine systems
- Depression appears to be a complex interaction between heritable and environmental factors.

RISK FACTORS
- General
  - Female sex
  - Lower socioeconomic status
  - Widowed, divorced, or separated marital status
  - Chronic physical health condition(s)
  - History of mental health problems
  - Family history of depression
  - Death of a loved one
  - Caregiving
  - Social isolation
  - Functional/cognitive impairment
  - Lack/loss of social support
  - Significant loss of independence
  - Uncontrolled or chronic pain
  - Insomnia/sleep disturbance
- Prevalence of depression in medical illness
  - Stroke (22–50%)
  - Cancer (18–50%)
- Myocardial infarction (15–45%)
- Parkinson disease (10–39%)
- Rheumatoid arthritis (13%)
- Diabetes mellitus (5–11%)
- Alzheimer dementia (5–15%)

**Suicide**
- Suicide is the 11th leading cause of death in the United States for all ages.
- Elderly account for 24% of all completed suicides.
- Suicide rates are highest for males aged >85 years (rate 55/100,000).

---

**DIAGNOSIS**

**HISTORY**
- Depressed mood most of the day, nearly every day, and/or loss of interest/pleasure in life for at least 2 weeks
- Other common symptoms include the following:
  - Feeling hopeless, helpless, or worthless
  - Insomnia and loss of appetite/weight (alternatively, hypersomnia with increased appetite/weight in atypical depression)
  - Fatigue and loss of energy
  - Somatic symptoms (headaches, chronic pain)
  - Neglect of personal responsibility or care
  - Psychomotor retardation or agitation
  - Diminished concentration, indecisiveness
  - Thoughts of death or suicide
- Screening with “SIGECAPS”
  - **Sleep**: changes in sleep habits from baseline, including excessive sleep, early waking, or inability to fall asleep
  - **Interest**: loss of interest in previously enjoyable activities (anhedonia)
  - **Guilt**: excessive or inappropriate guilt that may or may not focus on a specific problem or circumstance
  - **Energy**: perceived lack of energy
  - **Concentration**: inability to concentrate on specific tasks
  - **Appetite**: increase/decrease in appetite
  - **Psychomotor**: restlessness and agitation or the perception that everyday activities are too strenuous to manage
  - **Suicidality**: desire to end life or hurt oneself, harmful thoughts directed internally, recurrent thoughts of death or thoughts of homicidality

**PHYSICAL EXAM**
Mental status exam, thorough neurologic exam, and general physical exam to rule out other conditions

**DIFFERENTIAL DIAGNOSIS**
Concurrent medical conditions, cognitive disorders, and medications may cause symptoms that mimic depression:
Medical conditions: hypothyroidism, vitamin B₁₂ or folate deficiency, liver or renal failure, cancers, stroke, sleep disorders, electrolyte imbalances, Cushing disease, chronic fatigue syndrome
- Dementia and neurodegenerative disorders
- Delirium
- Medication induced: interferon-α, β₂-blockers, isotretinoin, benzodiazepines, glucocorticoids, levodopa, clonidine, H₂ blockers, baclofen, varenicline, metoclopramide, reserpine
- Psychiatric disorders: adjustment disorder with depressed mood, grief reaction, bipolar disorder, dysthymic disorder, anxiety disorders, substance abuse–related mood disorders, psychotic disorders

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Initial laboratory evaluation is done primarily to rule out potential medical factors that could be causing symptoms.
- Thyroid-stimulating hormone (hypothyroidism)
- Complete blood count with differential (anemia, infection)
- Vitamin B₁₂, folic acid (deficiencies)
- Urinalysis (urinary tract infection, glucosuria)
- Comprehensive metabolic panel (uremia, hypo- or hyperglycemia, hypo- or hypernatremia, hypercalcemia, liver failure)
- Urine drug screen
- 24-hour urine-free cortisol (Cushing disease)

**Follow-Up Tests & Special Considerations**
Additional testing for possible confounding medical and cognitive disorders, as warranted; may consider a sleep study for patients with decreased energy, sleep disturbances, changes in concentration, or psychomotor activity

**Diagnostic Procedures/Other**
Validated screening tools and rating scales:
- Geriatric Depression Scale: 15- or 30-point scales
- Patient Health Questionnaire (PHQ-2 and PHQ-9)
- Hamilton Depression Rating Scale
- Beck Depression Inventory
- Cornell Scale for Depression in Dementia

**TREATMENT**
Although response alone, usually interpreted as a 50% reduction in symptoms, can be clinically meaningful, the goal is to treat patients to the point of remission (i.e., essentially the absence of depressive symptoms).

**GENERAL MEASURES**
- Lifestyle modifications:
  - Increase physical activity.
– Improve nutrition.
– Encourage social interactions.
– Exercise: may be beneficial for depression in the elderly population (2)[A]
• Psychotherapy: Studies do show some benefit in depressed elderly patients (3)[B]:
  – Cognitive-behavioral therapy
  – Problem-solving therapy
  – Interpersonal therapy
  – Psychodynamic psychotherapy

**MEDICATION**
• Typically, more conservative initial dosing and titration of antidepressants in the elderly, starting with 1/2 of the usual initiation dose and increasing within 2 to 4 weeks, as tolerated
• Continue titrating dose every 2 to 4 weeks, as appropriate, to reach an adequate treatment dose.

**First Line**
• Selective serotonin reuptake inhibitors (SSRIs) have been found to be effective in treating depression in the elderly and are considered first line in pharmacotherapy for depression (2)[A].
• No single SSRI clearly outperforms others in the class; choice of medication often reflects side effect profile or practitioner familiarity (4)[A]:
  – Citalopram: Start at 10 mg/day; treatment range 10 to 20 mg/day
  – Sertraline: Start at 25 to 50 mg/day; treatment range 50 to 200 mg/day
  – Escitalopram: Start at 10 mg/day; treatment range 10 to 20 mg/day
  – Fluoxetine: Start at 10 mg/day; treatment range 20 to 60 mg/day
  – Paroxetine: Start at 10 mg/day; treatment range 20 to 40 mg/day
• SSRIs should not be used concomitantly with monoamine oxidase inhibitors (MAOIs).
• Common side effects—increased risk of falls, nausea, diarrhea, sexual dysfunction

**Second Line**
• Atypical antidepressants: more effective than placebo in treatment of depression in the elderly, although additional studies are needed to better delineate patient factors that determine response:
  – Bupropion (sustained/twice a day and extended/once daily available): Start at 150 mg/day. Increase dose in 3 to 4 days. Treatment range 300 to 450 mg/day. Avoid in patients with elevated seizure risk, tremors, or anxiety (5)[A].
  – Venlafaxine (immediate- and extended-release available): Start at 37.5 mg/day extended release and titrate weekly. Treatment range 150 to 225 mg/day; may be associated with elevated blood pressure (BP) at higher doses (5)[C]
  – Duloxetine: Start at 20 to 30 mg/day. Treatment range 60 to 120 mg/day. Also, duloxetine may be associated with elevated BP (5)[A].
  – Mirtazapine: Start at 7.5 to 15.0 mg nightly. Treatment range 30 to 45 mg/day; can produce problems with dry mouth, weight gain, sedation, and cognitive dysfunction (5)[A]
  – Desvenlafaxine: 50 mg/day in am; higher doses do not confer additional benefit; 50 mg every other day if CrCl <30 mL/min (5)[A]

**ISSUES FOR REFERRAL**
Depression with suicidal ideation, psychotic depression, bipolar disorder, comorbid substance abuse issues, polypharmacy, severe or refractory illness
ADDITIONAL THERAPIES
- For patients who have not responded to initial SSRI trial:
  - Switch to a different SSRI medication, switch to an atypical antidepressant, or augment initial antidepressant with bupropion.
- 2nd-generation antipsychotic agents (5)[C]:
  - Aripiprazole: 2 to 5 mg/day. Treatment range 5 to 15 mg/day; can produce sedation, weight gain, increased cholesterol levels
  - Should only be used for augmentation in conjunction with other antidepressant medications
- Tricyclic antidepressants (TCAs):
  - Nortriptyline: 25 to 50 mg nightly. Treatment range 75 to 150 mg nightly; can produce anticholinergic effects, weight gain, increase risk of falls (5)[C]
  - TCAs have been shown to be effective in treating depression in the elderly. However, they are difficult for elderly patients to tolerate due to side effect profile and are potentially lethal in overdose, limiting their use as initial treatment agents (6)[A].
- MAOIs also appear more effective than placebo in the treatment of depression in the elderly. They are not used frequently in clinical practice due to potential side effects and necessary dietary restrictions (6)[A].
- Although not Food and Drug Administration approved, buspirone, lithium, or triiodothyronine is sometimes used off-label to augment a primary antidepressant.
- Evidence for benefit of antidepressants in the treatment of depression in patients with dementia is equivocal. Consideration should be made for a limited trial with close monitoring for symptom improvement or side effects and used only in patients with severe symptoms.
- Electroconvulsive therapy (ECT): has been shown to produce remission of depressive symptoms in the elderly. It should be considered as an initial option for patients with severe or psychotic depression.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture: equally beneficial as counseling
- St. John’s wort may have minimal benefit and has numerous drug interactions.
- Tryptophan and hydroxytryptophan: 150 to 300 mg/day; possible efficacy, additional investigation required

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Inpatient care is indicated in cases of imminent safety risk (e.g., acutely suicidal patients) or for those patients unable to care adequately for themselves due to depression.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Due to the delay of benefit following initiation of antidepressant therapy, it is necessary to ensure open communication with the patient to prevent premature discontinuation of therapy. An adequate explanation of potential side effects with instructions to call the office before discontinuing therapy is imperative.

Patient Monitoring
- A patient with severe depression who exhibits suicidality will require admission to an
appropriate facility.

- Monitor for worsening anxiety symptoms or increase in suicidality especially in the week following initiation of antidepressants.

**DIET**

No dietary restrictions are necessary, except for patients taking MAOIs, which necessitates dietary restriction of foods high in tyramine (i.e., certain cheeses and wines).

**PATIENT EDUCATION**

- Depression is a treatable illness.
- Medications may need to be taken for at least 2 to 4 weeks before any beneficial effect is noted and may take 6 to 8 weeks to reach maximum efficacy.
- Depression is often a recurring illness.
- National Suicide Prevention Lifeline at 1-800-273-TALK (8255) is a free, 24-hour hotline available to anyone in suicidal crisis or emotional distress. Calls will be routed to the nearest crisis center.

**PROGNOSIS**

- Treatment outcomes in the elderly may be worse than in the general population, possibly mediated by physical comorbidities and other factors.
- Depending on the population studied and specific clinical measures used, estimates vary for initial clinical response and remission (between 30% and 70%).

**COMPLICATIONS**

- Impairment in social, occupational, or interpersonal functioning
- Difficulty performing activities of daily living and self-care
- Increase in medical services utilization and increased costs of care
- Increase risk of suicide

**REFERENCES**

SEE ALSO
Algorithms: Depressed Mood Associated with Medical Illness; Depressive Episode, Major

CODES

ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- F03 Unspecified dementia
- F43.21 Adjustment disorder with depressed mood

CLINICAL PEARLS
- Depression is not a normal part of aging.
- Depression in the elderly may be difficult to diagnose precisely due to medical and cognitive comorbidities.
- Depression may present primarily with cognitive dysfunction, and this may improve with treatment of the depression.
- SSRIs are considered first-line therapy for safety and tolerability. A full remission may take upward of 12 weeks of treatment. Long-term treatment may be needed to prevent recurrence.
- A multidisciplinary approach to the treatment of depression is often the most efficacious.
BASICS

DESCRIPTION

- Major depressive disorder (MDD) that recurs or has its onset in the postpartum period
- May also occur in mothers adopting a baby or in fathers
- Postpartum depression (PPD) is similar to nonpregnancy depression (sleep disorders, anhedonia, psychomotor changes, etc.); it most often has its onset within the first 12 weeks postpartum yet can occur within 1 year after delivery.
- Different than postpartum “blues” (sadness and emotional lability), which is experienced by 30–70% of women and has an onset and resolution within first 10 days postpartum

EPIDEMIOLOGY

Incidence
14.5% of women have a new episode of major or minor depression during postpartum period (1).

Prevalence
- >50% of women with PPD enter pregnancy depressed or have an onset during pregnancy (2).
- As many as 19.2% women suffer from depression within 3 months postpartum period.

ETIOLOGY AND PATHOPHYSIOLOGY

- May be related to sensitivity in hormonal fluctuations, including estrogen; progesterone; and other gonadal hormones as well as neuroactive steroids; cytokines; hypothalamic–pituitary–adrenal (HPA) axis hormones; altered fatty acid, oxytocin, and arginine vasopressin levels; and genetic and epigenetic factors
- Multifactorial including biologic–genetic predisposition in terms of neurobiologic deficit, destabilizing effects of hormone withdrawal at birth, inflammation, and psychosocial stressors

RISK FACTORS

- Previous episodes of PPD
- History of MDD
- MDD during pregnancy
- Anxiety during pregnancy
- History of premenstrual dysphoria
- Family history of depression
- Poor pregnancy outcomes (preterm birth, stillbirth, neonatal death, major malformations)
- Substance Use
- Unwanted pregnancy
- Socioeconomic stress
- Low self-esteem
- Young maternal age
- Marital conflict
- Multiple births
- African Americans and Hispanics may have higher rates of PPD.
- Postpartum pain, sleep disturbance, and fatigue
- Recent immigrant status
- Increased stressful life events
- History of childhood sexual abuse
- Decision to decrease antidepressants during pregnancy
- Intimate partner violence (3)
- Prepregnancy diabetes

**GENERAL PREVENTION**
- Universal screening, using validated rating scales, during pregnancy and postpartum year for better detection. Evidence suggests that screening pregnant and postpartum women for depression reduces depressive symptoms in women with depression and reduce the prevalence of depression in a given population. Evidence for pregnant women was less robust but is also consistent with the evidence for postpartum women regarding the benefits of screening, the benefits of treatment, and screening instrument accuracy (4)[A].
- Psychotherapy/Counseling, particularly using cognitive behavioral therapy (CBT) and interpersonal therapy (IPT) based interventions, has been shown to be effective in small randomized trials in the prevention of PPD in at-risk individuals, but the USPSTF concludes that further research is needed (5)[A].
- Use of SSRIs, specifically sertraline, may be effective in preventing PPD in women at high risk for PPD (5)[A].

**COMMONLY ASSOCIATED CONDITIONS**
- Bipolar mood disorder
- Depressive disorder not otherwise specified
- Dysthymic disorder
- Cyclothymic disorder
- MDD
- Postpartum blues

**DIAGNOSIS**

**HISTORY**
- Decreased interest in formerly compelling or pleasurable activities
- Depressed/Low mood
- Increased/decreased sleep
- Guilt, low self-esteem
- Decreased energy
- Decreased concentration
- Increased/decreased appetite
- Psychomotor agitation or retardation
- Suicidal ideation

**DIFFERENTIAL DIAGNOSIS**
- Baby blues: not a psychiatric disorder; mood lability resolves within days.
- Postpartum psychosis: a psychiatric emergency
- Postpartum anxiety/panic disorder
- Postpartum obsessive-compulsive disorder
- Hypothyroidism
- Postpartum thyroiditis: can occur in up to 5.7% of patients in the United States and can present as depression
- Bipolar disorder, depressive episode

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
No blood testing is necessary, but selective tests based on history and symptoms might include complete blood count (CBC), thyroid-stimulating hormone (TSH)

**Follow-Up Tests & Special Considerations**
Urine analysis, urine drug screen, β-hCG

**Diagnostic Procedures/Other**
- Edinburgh Postnatal Depression Scale is a validated screening tool.
- The Patient Health Questionnaire-9 (PHQ-9) is a validated commonly used screening tool.
- Edinburgh Postnatal Depression Scale (partner version): to be completed by mother’s partner to obtain his/her view of mother’s depression

**TREATMENT**

**GENERAL MEASURES**
- Assess for the presence of suicidal ideation.
- Assess for the presence of homicidal ideation and thoughts of harming the baby (infanticide).
- Suicidal ideation, homicidal ideation, or infanticide ideation may require immediate hospitalization.
- Psychotherapy may be an effective monotherapy for mild to moderate depressive symptoms.
- Strongly consider pharmacotherapy when symptoms of depression are severe.
- Outpatient individual psychotherapy in combination with pharmacotherapy may be beneficial.

**MEDICATION**

**First Line**
- For nonbreastfeeding women, selection of antidepressants is similar to nonpostpartum patients.
- Selective serotonin reuptake inhibitors (SSRIs) are generally effective and safe. Paroxetine has been associated with fetal cardiac defects when used during pregnancy:
  - Sertraline (Zoloft): 50 to 200 mg/day PO
  - Fluoxetine (Prozac): 20 to 80 mg/day PO
  - Paroxetine (Paxil): 20 to 50 mg/day; PO given at bedtime (associated with very small increase in risk of cardiovascular defects with first trimester use)
  - Citalopram (Celexa): 20 to 40 mg/day PO
  - Escitalopram (Lexapro): 10 to 20 mg/day PO
- Serotonin-norepinephrine reuptake inhibitors (SNRIs):
  - Venlafaxine (Effexor XR): 75 to 225 mg/day PO
  - Duloxetine (Cymbalta): 60 to 120 mg/day PO
  - Desvenlafaxine (Pristiq): 50 to 100 mg/day PO
Atypical antidepressants:
- Bupropion (Wellbutrin): 150 to 450 mg/day PO (no sexual dysfunction, activating)
- Mirtazapine (Remeron): 15 to 45 mg/day PO at bedtime (increases appetite and is sedating at lower doses, no sexual dysfunction)

Tricyclic antidepressants (TCAs), particularly nortriptyline, have been shown to be as effective as SSRIs, yet are more lethal in overdose and have increased rates of unfavorable side effects.
- Nortriptyline: 75 to 150 mg/day PO given at bedtime
- Bipolar disorder requires treatment with mood stabilizer.

Among breastfeeding mother
- Breastfeeding should generally not preclude treatment with antidepressants.
- SSRIs and some other antidepressants are considered a reasonable option during breastfeeding.
- All antidepressants are excreted in breast milk but are generally compatible with lactation.
- Sertraline and paroxetine have the lowest translactal passage and are considered most compatible with breastfeeding.
- Translactal passage is greater with fluoxetine, citalopram (3)[B], and venlafaxine.
- There is a case report that links Wellbutrin exposure to infant seizures. Although most studies report that it is safe to use during pregnancy and breastfeeding, a few studies have associated it with a small increase in cardiovascular defects with first trimester use.
- Start with low doses and increase slowly. Minimize polypharmacy. Attempt to maximize use of only one psychotrophic medication at a time. Monitor infant for adverse side effects.
- Continuing an efficacious medication is preferred over switching antidepressants to avoid exposing the mother and infant to the risks of untreated PPD (3)[B].
- Breastfeeding women need additional education and support regarding the risks and benefits of use of antidepressants during breastfeeding.
- Consider negative effects of untreated PPD on infant and child development.
- Discussions of the treatment options with the patient and her partner when possible. Take into account the patient’s personal psychiatric history and previous response to treatment, the risks of no treatment or undertreatment, available data about the safety of medications during breastfeeding, and her individual expectations and treatment preferences.
- For further information: http://toxnet.nlm.nih.gov/

Second Line
Consider switching to a different antidepressant if patient has a lack of response. Augmentation may be necessary in the setting of treatment resistant postpartum depression. Electroconvulsive therapy (ECT) is an option for depressed postpartum women who do not respond to antidepressant medications, have severe or psychotic symptoms, cannot tolerate antidepressant medications, are actively engaged in suicidal self-destructive behaviors, or have a previous history of response to ECT.

ISSUES FOR REFERRAL
- Obtain psychiatric consultation for patients with psychotic symptoms.
- Strongly consider immediate hospitalization if delusions or hallucinations are present.
- Hospitalization is indicated if mother’s ability to care for self and/or infant is significantly compromised.

ADDITIONAL THERAPIES
Psychoeducation, including providing reading material for the patient and family.
Psychotherapy: Interpersonal psychotherapy, cognitive behavioral therapy and brief psychodynamic therapy have shown to be effective.

SURGERY/OTHER PROCEDURES
Brexanolone was approved by the FDA in March 2019 for postpartum depression. It is a rapidly acting antidepressant that is administered as a continuous IV infusion over a period of 60 hours. There is restricted access to this medication. It is only administered at sites enrolled in the Risk Evaluation and Mitigation Strategy Program, and it is very expensive. Consider in women with severe postpartum depression who refuse or do not respond to ECT (6).

- Requires constant monitoring with pulse oximetry
- FDA recommends that providers monitor patient at least every 2 hours for excessive sedation and loss of consciousness.
- Side effects include dry mouth, hot flashes/flushing, excessive sedation, loss of consciousness, dizziness.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Breastfeeding has been associated with reduced stress and improved maternal mood.
- Infant massage, infant sleep intervention, exercise, and bright light therapy may be beneficial.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

ALERT
Obtain psychiatric consultation for patients with refractory depression or psychotic symptoms. If delusions or hallucinations are present, strongly consider immediate hospitalization. The psychotic mother should not be left alone with the baby.

- Admission criteria/initial stabilization: presence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming baby and/or inability to care for self or infant, severe weight loss
- Discharge criteria
  - Absence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming the baby
  - Mother must be able to care for self and infant.

ONGOING CARE

FOLLOW UP-RECOMMENDATIONS

Patient Monitoring
- Collaborative care approach, including primary care visits and case manager follow-ups
- Consultation with the infant’s doctor, particularly if the mother is breastfeeding while taking psychotropic medications

DIET
- Good nutrition and hydration, especially when breastfeeding
- Mixed evidence to support the addition of multivitamin with minerals and omega-3 fatty acids

PATIENT EDUCATION
This Isn’t What I Expected: Overcoming Postpartum Depression, by Karen R. Kleiman and Valerie Davis Raskin

Down Came the Rain: My Journey Through Postpartum Depression, by Brooke Shields, 2005

Behind the Smile: My Journey Out of Postpartum Depression, by Marie Osmond, Marcia Wilkie, and Judith Moore, 2001

Web resources
- Postpartum Support International: http://www.postpartum.net/
- La Leche League: http://www.llli.org/
- http://www.womensmentalhealth.org/
- http://www.motherisk.org/

PROGNOSIS

- Treatment of maternal depression to remission has been shown to have a positive impact on children’s mental health.
- Some patients, particularly those with undertreated or undiagnosed depression, may develop chronic depression requiring long-term treatment.
- Untreated maternal depression is linked to impaired mother–infant bonding and cognitive and language development delay in infants and children.
- Postpartum psychosis is associated with tragic outcomes such as maternal suicide and infanticide.

COMPLICATIONS

- Suicide
- Self-injurious behavior
- Psychosis
- Neglect of baby
- Harm to the baby
- Preterm and low-birth-weight baby

REFERENCES

ADDITIONAL READING

CODES

ICD10

- F53 Puerperal psychosis
- O90.6 Postpartum mood disturbance

CLINICAL PEARLS

- PPD is a common, debilitating medical condition that impairs a mother’s ability to function and interact with her infant and family.
- Universal screening for depression is recommended during the 1st and 3rd trimester and at regular intervals during the postpartum period.
- Early diagnosis and treatment are vital, as untreated PPD can lead to developmental difficulties for the infant and prolonged disability and suffering for the mother.
- Psychotherapy may be an effective monotherapy for mild to moderate depressive systems. In severe postpartum depression, use of medications is strongly urged.
- Antidepressant treatment is safe during pregnancy, and breastfeeding and treatment should be individualized for each mom (3)[B].
DEPRESSION, TREATMENT RESISTANT
Michelle Magid, MD, MBA • Isadora Fox, MSN, RN, PMHNP, APRN-BC

BASICS

DESCRIPTION
- Major depressive disorder (MDD) that has failed to respond to ≥2 adequate trials of antidepressant therapy in ≥2 different classes
- Individual antidepressants must be given for 6 weeks at standard doses before being considered a failure.

EPIDEMIOLOGY
- Depression affects >16 million people in the United States and >350 million people worldwide.
- The average adult has a 16% lifetime risk of MDD, with majority experiencing onset before the age of 30
- Approximately 1/3 of patients with MDD will develop treatment-resistant depression.

ETIOLOGY AND PATHOPHYSIOLOGY
- Unclear. Low levels of neurotransmitters (serotonin, norepinephrine, dopamine) have been indicated.
- Serotonin has been linked to irritability, hostility, and suicidal ideation.
- Norepinephrine has been linked to low energy.
- Dopamine may play a role in low motivation and depression with psychotic features.
- Environmental stressors, such as abuse and neglect, may affect both the function and levels of neurotransmitters.
- Inflammation and oxidative stress in the brain can contribute to treatment-resistant depression.

Genetics
A genetic abnormality in the serotonin transporter gene (5-HTTLPR) may increase risk for treatment-resistant depression.

RISK FACTORS
- Severity of disease
- Mislabeling bipolar patients as depressed
- Comorbid medical disease (including chronic pain)
- Comorbid personality disorder
- Comorbid anxiety disorder
- Comorbid substance use disorder
- Genetic familial predisposition to poor response to antidepressants

GENERAL PREVENTION
- Medication adherence in combination with psychotherapy
- Maintenance electroconvulsive therapy (ECT) may prevent relapse.
COMMONLY ASSOCIATED CONDITIONS
- Suicide
- Bipolar disorder
- Substance use disorders
- Anxiety disorders
- Dysthymia
- Eating disorders
- Somatic symptom disorders

DIAGNOSIS

HISTORY
- Symptoms are the same as in MDD. However, patients do not respond to standard form of treatment.
- Important to screen for suicidality in treatment-resistant depression
- Screening with SIGECAPS
  - Sleep: too much or too little
  - Interest: inability to enjoy activities
  - Guilt: excessive and uncontrollable
  - Energy: poor
  - Concentration: inability to focus on tasks
  - Appetite: too much or too little
  - Psychomotor changes: restlessness/agitation or slowing/lethargy noted by others
  - Suicidality: desire to end life or feeling hopeless

PHYSICAL EXAM
Mental status exam may reveal poor hygiene, limited eye contact, poor relatedness, restricted affect, tearfulness, weight loss or gain, psychomotor retardation or agitation.

DIFFERENTIAL DIAGNOSIS
- Bipolar disorder
- Persistent depressive disorder
- Posttraumatic stress disorder
- Dementia
- Early-stage Parkinson disease
- Personality disorder
- Medical illness such as malignancy, thyroid disease, HIV, anemia
- Substance use disorders

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Used to rule out medical factors that could be causing/contributing to treatment resistance
- CBC
- Complete metabolic profile, including liver tests, calcium, and glucose
- Urine drug screen
- Thyroid-stimulating hormone (TSH)
- Vitamin D level (25-OH vitamin D)
- Vitamin B₁₂
- Folate
- Urinalysis
- FSH, LH if applicable
- HCG, if applicable
- Testosterone, if applicable
- CT or MRI of the brain if neurologic disease, tumor, or dementia is suspected

**Follow-Up Tests & Special Considerations**
Delirium and dementia often look like depression.

**Diagnostic Procedures/Other**
- Depression is a clinical diagnosis.
- Validated depression rating scales to assist
  - Beck Depression Inventory
  - Hamilton Depression Rating Scale
  - Patient Health Questionnaire 9 (PHQ-9)
  - Edinburgh Postnatal Depression Scale if pregnant or postpartum

**TREATMENT**

**MEDICATION**

**First Line**
- Please see “Depression” topic. When those fail, augmentation and combination strategies are as follows:
  - Antidepressants in combination
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + bupropion (start 100 mg BID; max dose 450 mg total) (1)[B]
    - Tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs) may be used in combination. Proceed with caution due to risk of serotonin syndrome; citalopram (start 20 mg/day; max dose 40 mg/day) + nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime).
    - Serotonin and norepinephrine reuptake inhibitors (SNRI) and noradrenergic and specific serotonergic antidepressant (NaSSA) may also be used in combination, such as venlafaxine extended release (start 75 mg/day; max dose 225 mg/day) and mirtazapine (start 15 mg/day; max dose 45 mg/day).
  - Antidepressants + antipsychotics
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + aripiprazole (start 2 mg/day; up to 20 mg/day, different mechanism of action at higher doses) or + risperidone (start 0.5 to 1.0 mg at bedtime; max dose 6 mg/day) or + quetiapine (start 25 mg at bedtime; titrate to 100 to 300 mg at bedtime; max dose 600 mg/day) (1)[A]
    - Olanzapine/fluoxetine combination (start 3 mg/25 mg to 12 mg/50 mg at bedtime) (1)[A]
  - Antidepressant + lithium
    - TCA: nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime) + lithium (start 300 mg at bedtime; max dose 900 mg BID)
o SSRI: citalopram (start 20 mg/day; max dose 40 mg QD) + lithium (start 300 mg at bedtime; max dose 900 mg BID) (1)[A]

- In all combinations, citalopram (Celexa) can be replaced with other SSRIs such as fluoxetine (Prozac) 20 to 80 mg/day, sertraline (Zoloft) 50 to 200 mg/day, and escitalopram (Lexapro) 10 to 20 mg/day or with serotonin-norepinephrine reuptake inhibitors (SNRIs) such as duloxetine (Cymbalta) 30 to 120 mg/day, venlafaxine XR (Effexor XR) 75 to 225 mg/day, or desvenlafaxine (Pristiq) 50 to 100 mg/day, or with a noradrenergic and specific serotonergic antidepressant (NaSSA) mirtazapine (Remeron) 15 to 45 mg at bedtime.

- Maximum doses for medication in treatment-resistant cases may be higher than in treatment-responsive cases.

**Second Line**

- Citalopram (start 20 mg/day; max dose 40 mg/day) + triiodothyronine (T3) (12.5 to 50.0 μg/day) (1)[B]
- Citalopram (start 20 mg/day; max dose 40 mg/day) + buspirone (start 7.5 mg twice a day; max dose 30 mg twice a day) (1)[B]
- Citalopram (start 20 mg/day; max dose 40 mg/day) + lisdexamfetamine (Vyvanse) (20 to 50 mg every morning) (1)[B]
- Antidepressant in combination with therapy, particularly cognitive-behavioral therapy (CBT) (2)[A]

- Monoamine oxidase inhibitor (MAOI)
  - Tranylcypromine (Parnate): Start 10 mg BID and increase 10 mg/day every 1 to 3 weeks; max dose 60 mg/day
  - Selegiline transdermal (Emsam patch): Apply 6-mg patch daily and increase 3 mg/day; max dose 12 mg/day
  - Side-effect profile (e.g., hypertensive crisis), drug–drug interactions, and dietary restrictions make MAOIs less appealing. Patch version does not require dietary restrictions at lower doses.
  - High risk of serotonin syndrome if combined with another antidepressant. 2-week washout period is advised.

**ISSUES FOR REFERRAL**

Treatment-resistant depression should be managed in consultation with a psychiatrist.

**ADDITIONAL THERAPIES**

- First line
  - ECT: brief administration of electrical stimulation to the brain via superficial electrode placement
    - Safe and cost-effective option for treatment-resistant and life-threatening depression, with a 66.6% response rate (3)[A]
    - Known to rapidly relieve suicidality, psychotic depression, and catatonia
    - Cognitive side effects during treatment can occur but are more likely with bilateral lead placement
    - Three types of lead placements
      - Right unilateral
      - Bitemporal
      - Bifrontal
Second line
- Deep brain stimulation (DBS): surgical implantation of intracranial electrodes, connected to an impulse generator implanted in the chest wall:
  - Reserved for those who have failed medications, psychotherapy, and ECT
  - Preliminary data is promising, showing 40–70% response rate and 35% remission rate. Further trials are being done.
- Transcranial magnetic stimulation (TMS): noninvasive brain stimulation technique that is generally safe
  - Currently, only FDA-approved for less severe forms of the illness
- Vagus nerve stimulation (VNS): surgical implantation of electrodes onto left vagus nerve
  - Its use in treatment-resistant depression has become limited in recent years.
- Ketamine (0.5 mg/kg single-dose infusion): Studies show evidence of rapid improvement in mood and suicidal thinking. Currently used off-label for treatment resistant depression (4) [B]. Esketamine, an intranasal spray, in conjunction with an oral antidepressant, has been FDA approved for treatment resistant depression. Dosing is 28 mg, 56 mg, or 84 mg twice a week for 1–4 weeks, followed by taper and/or maintenance treatment.
  - The effects of ketamine and esketamine appear temporary, diminishing after days to weeks (4). Continued studies are focusing on dosing and frequency of administration to maintain longer-lasting response and remission.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient care is indicated for severely depressed, psychotic, catatonic, or suicidal patients.
- Discharge criteria: symptoms improving, no longer suicidal, psychosocial stressors addressed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Frequent visits (i.e., every month)
- During follow-up, evaluate side effects, dosage, and effectiveness of medication as well as need for referral to ECT.
- Patients who have responded to ECT may need maintenance treatments (q3–12 wk) to prevent relapse.
- Combination of lithium/nortriptyline after ECT appears to be as effective as maintenance ECT in reducing relapse.

DIET
Patients on MAOIs need dietary restriction of foods rich in tyramine.

PATIENT EDUCATION
- Educate patients that depression is a medical illness, not a character defect.
- Review signs and symptoms of worsening depression and when patient needs to come in for further evaluation.
- Discuss safety plan to address suicidal thoughts.

PROGNOSIS
With medication adherence, close follow-up, improved social support, and psychotherapy, prognosis improves.
COMPLICATIONS
- Suicide
- Disability
- Poor quality of life

REFERENCES

CODES
ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified

CLINICAL PEARLS
- Treatment-resistant depression is common, affecting 1/3 of those with MDD.
- Combination and augmentation strategies with antidepressants, antipsychotics, therapy, and mood stabilizers can be helpful.
- ECT should be considered in severe and life-threatening cases.
DERMATITIS HERPETIFORMIS
Abdul Aleem, MD • Hiral Shah, MD, FASGE, FAGA, FACG

BASICS

DESCRIPTION
- Dermatitis herpetiformis (DH) presents as a chronic, relapsing, polymorphous, intensely pruritic, erythematous papulovesicular eruption with symmetrical distribution primarily involving extensor skin surfaces of the elbows, knees, buttocks, back, and scalp.
- DH is an autoimmune disease associated with gluten sensitivity with genetic, environmental, and immunologic influences.
- DH is distinguished from other bullous diseases by characteristic histologic and immunologic findings as well as associated gluten-sensitive enteropathy (GSE).
- System(s) affected: skin
- Synonym(s): Duhring disease, Duhring-Brocq disease

EPIDEMIOLOGY
- Occurs most frequently in those of Northern European origin
- Rare in persons of Asian or African American origin
- Predominant age: most common in 4th and 5th decades but may present at any age
- Childhood DH is rare in most countries, although an Italian study showed 27% of patients were age of <10 years and 36% age of <20 years.
- Predominant gender: adults: male > female (1.5:1 in the United States, 2:1 worldwide); children: female > male

Incidence
1/100,000 persons per year in the United States

Prevalence
11/100,000 persons in the U.S. population; as high as 39/100,000 persons worldwide

ETIOLOGY AND PATHOPHYSIOLOGY
- Evidence suggests that epidermal transglutaminase (eTG) 3, a keratinocyte enzyme involved in cell envelope formation and maintenance, is the autoantigen in DH.
- eTG is highly homologous with tissue transglutaminase (tTG), which is the antigenic target in celiac disease and GSE.
- The initiating event for DH is presumed to be the interaction of wheat peptides with tTGs, which results in the formation of an autoantigen with high affinity for particular class II major histocompatibility complex (MHC) molecules.
- Presentation of the autoantigen leads to activation of T cells and the humoral immune system.
- IgA antibodies against tTG cross-react with eTG and result in IgA-eTG immune complexes that are deposited in the papillary dermis. Subsequent activation of complement and recruitment of neutrophils to the area result in inflammation and microabscesses.
- Skin eruption may be delayed up to 5 to 6 weeks after exposure to gluten.
- Gluten applied directly to the skin does not result in the eruption, whereas gluten taken by mouth or rectum does. This implies necessary processing by the GI system.
Thought to be immune complex–mediated disease

Genetics
- High association with human leukocyte antigen (HLA)-DQ2 (95%), with remaining patients being positive for DQ8, DR4, or DR3
- Strong association with combination of alleles DQA1*0501 and DQB1*0201/0202, DRB1*03 and DRB1*05/07, or DQA1*0301 and DQB1*0302

RISK FACTORS
- GSE: >90% of those with DH will have GSE, which may be asymptomatic.
- Family history of DH or celiac disease

GENERAL PREVENTION
Gluten-free diet (GFD) results in improvement of DH and reduces dependence on medical therapy. GFD also may reduce the risk of lymphomas associated with DH.

COMMONLY ASSOCIATED CONDITIONS
- Hypothyroidism is the most common condition associated with DH.
- GSE, gluten ataxia
- Gastric atrophy, hypochlorhydria, pernicious anemia
- GI lymphoma, non-Hodgkin lymphoma
- Hyperthyroidism, thyroid nodules, thyroid cancer
- IgA nephropathy
- Autoimmune disorders, including systemic lupus erythematosus, dermatomyositis, Sjögren syndrome, rheumatoid arthritis, sarcoidosis, Raynaud phenomenon, insulin-dependent diabetes mellitus, myasthenia gravis, Addison disease, vitiligo, alopecia areata, primary biliary cirrhosis, and psoriasis

DIAGNOSIS
Diagnosis of DH involves a clinicopathologic correlation among clinical presentation, histologic and direct immunofluorescence (DIF) evaluation, serology, and response to therapy or dietary restriction.

HISTORY
- Waxing and waning, intensely pruritic eruption with papules and tiny vesicles
- Eruption may worsen with gluten intake.
- GI symptoms may be absent or may not be reported until prompted.

PHYSICAL EXAM
- The classic lesions of DH are described as symmetric, grouped, erythematous papules and vesicles.
- More commonly presents with erosions, excoriations, lichenification, hypopigmentation, and/or hyperpigmentation secondary to scratching and healing of old lesions
- Areas involved include extensor surfaces of elbows (90%), knees (30%), shoulders, buttocks, and sacrum. The scalp is also frequently affected. Oral lesions are rare.
- In children, purpura may be visible on digits and palmoplantar surfaces.
- Adults with associated enteropathy are most often asymptomatic, with about 20% experiencing
steatorrhea and <10% with findings of bloating, diarrhea, or malabsorption.  
* Children with associated enteropathy may present with abdominal pain, diarrhea, iron deficiency, and reduced growth rate.

**DIFFERENTIAL DIAGNOSIS**

* In adults  
  - Bullous pemphigoid: linear deposition of C3 and IgG at the basement membrane zone  
  - Linear IgA disease: homogeneous and linear deposition of IgA at the basement membrane zone, absence of GSE  
  - Prurigo nodularis  
  - Urticaria: wheals, angioedema, dermal edema  
  - Erythema multiforme

* In children  
  - Atopic dermatitis: face and flexural areas  
  - Scabies: interdigital areas, axillae, genital region  
  - Papular urticaria: dermal edema  
  - Impetigo

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

* Serum IgA tTG antibodies: Detection of tTG antibodies was noted to be up to 95% sensitive and >90% specific for DH in patients on unrestricted diets (1,2)[A].  
* Serum IgA eTG antibodies: Antibodies to eTG, the primary autoantigen in DH, were shown to be more sensitive than antibodies to tTG in the diagnosis of patients with DH on unrestricted diets (95% vs. 79%) but is not widely available in all labs (1,2)[A].  
* Serum IgA endomysial antibodies (EMA): Antibodies to EMA have a sensitivity between 50% and 100% and a specificity close to 100% in patients on unrestricted diets but is more expensive, time-consuming, and operator-dependent than tTG (2).

**Follow-Up Tests & Special Considerations**

* Serologic assessment of anti-tTG and anti-eTG correlate with intestinal involvement of disease and in conjunction with anti-EMA may be useful in monitoring major deviations from GFD (1,2).  
* Genetic testing for haplotypes HLA-DQ2 and HLA-DQ8 can also be offered to patients to determine genetic susceptibility, to screen patients with high risk of CD, or if the diagnosis is not clear (1).

**Diagnostic Procedures/Other**

* The gold standard test to establish a diagnosis of DH is DIF of the perilesional skin that demonstrate characteristic granular IgA deposits in dermal papillae and/or basement membrane (1,2)[A]. It is this key diagnostic feature that differentiates this blistering skin condition from all other dermatologic diseases (3).  
* DIF has a sensitivity and specificity of close to 100% (1).  
* In patients with high suspicion for DH with a negative DIF, another perilesional skin biopsy should be obtained from a different site (1).  
* Histopathology of these lesions with routine staining reveals neutrophilic microabscesses in the tips of the dermal papillae and may show subepidermal blistering (1,2).
TREATMENT

GENERAL MEASURES
● GFD is the mainstay of treatment in DH and can lead to complete resolution of symptoms (1,2)[A].
● Typically requires 18 to 24 months of strict adherence to GFD prior to resolution of skin lesions without any additional treatment
● Lesions can recur within 12 weeks of reintroduction of gluten.

MEDICATION
● Despite being on GFD, the lesions of DH take several months to clear, and active lesions warrant additional treatment (3).
● Medications are useful for immediate symptom management but should only be used as an adjunct to dietary modification (2).

First Line
● Dapsone is approved by the FDA for use in DH and is the most widely used medication (2,4)[A].
● Initial dosing of 25 to 50 mg/day on a strict GFD typically results in improvement of symptoms within 24 to 48 hours (1,3)[C].
● It is recommended to use minimum effective dose with slow titration based on patient’s response and tolerability. Average maintenance dose is 1 mg/kg/day (50 to 150 mg/day) and can be increased up to 200 mg to obtain better symptom control.
● Minor outbreaks on the face and scalp are common even with treatment; not ideal for long-term use in DH
● Dapsone works by inhibiting neutrophil recruitment and IL-8 release, inhibiting the respiratory burst of neutrophils, and protecting cells from neutrophil-mediated injury, thereby suppressing the skin reaction. It has no role in preventing IgA deposition or mitigating the immune reaction in the gut (2,4).
● Precautions
  – Common side effects include nausea, vomiting, headache, dizziness, weakness, and hemolysis.
  – A drop in hemoglobin of 1 to 2 g is characteristic with dapsone 100 mg/day.
  – G6PD deficiency increases severity of hemolytic stress. Dapsone should be avoided, if possible, in those who are G6PD-deficient.
  – Dose-related methemoglobinemia may occur with doses >100 mg/day. Cimetidine may reduce the severity of this side effect.
  – Risk of distal motor neuropathy

ALERT
● Monitor for potentially fatal dapsone-induced sulfone syndrome: fever, jaundice and hepatic necrosis, exfoliative dermatitis, lymphadenopathy, methemoglobinemia, and hemolytic anemia.
● Can occur 48 hours or 6 months after treatment, most often 5 weeks after initiation

Pediatric Considerations
● <2 years: Dosing is not established.

- >2 years: 0.5 to 1.0 mg/kg/day

**Pregnancy Considerations**
- Category C: Safety during pregnancy is not established.
- Secreted in breast milk and will produce hemolytic anemia in infants.
- Adherence to a strict GFD 6 to 12 months before conception should be considered with the hope of eliminating need for dapsone during pregnancy.

**Second Line**
- High-potency topical steroids can be used acutely to control symptoms until dapsone becomes effective (1)[C].
- Sulfapyridine (1 to 2 g/day) is FDA-approved for use in DH and is thought to be the active metabolite in sulfasalazine (2 to 4 g/day) (2,5)[B]. Common side effects include nausea, vomiting, and anorexia. Enteric-coated form may reduce side effects. Other side effects include agranulocytosis, hypersensitivity reactions, hemolytic anemia, proteinuria, and crystalluria (2,5).
- Topical steroids and 3rd-generation antihistamines can be used to provide relief from symptoms of pruritus and itching.

**ISSUES FOR REFERRAL**
Over time, the management of DH warrants an interdisciplinary treatment that includes providing a referral to dermatologist, gastroenterologist, and registered dietitian (1,2).

**ADDITIONAL THERAPIES**
A single case report described topical dapsone therapy as potential alternative treatment or as an adjunct to oral dapsone to decrease systemic exposure and risk of severe side effects. However, it has not been studied extensively (6)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Every 6 to 12 months by physician and dietitian to evaluate GFD adherence and recurrence of symptoms.
- Adherence to GFD can be monitored with serologic levels of anti-tTG, anti-eTG, and EMA levels (1).
- Patients on dapsone require lab monitoring weekly for the 1st month, biweekly for 2 months, and then every 3 months for the duration of medication use (1,5).

**DIET**
- Grains that should be avoided: wheat (includes spelt, kamut, semolina, and triticale), rye, and barley (including malt).
- Safe grains (gluten-free): rice, amaranth, buckwheat, corn, millet, quinoa, sorghum, teff (an Ethiopian cereal grain), and oats.
- Care should be taken to avoid gluten-free grains that are contaminated with sources of gluten during processing such as oats.
- Sources of gluten-free starches that can be used as flour alternatives.
– Cereal grains: amaranth, buckwheat, corn, millet, quinoa, sorghum, teff, rice (white, brown, wild, basmati, jasmine), and Montina
– Tubers: arrowroot, jicama, taro, potato, and tapioca
– Legumes: chickpeas, lentils, kidney beans, navy beans, pea beans, peanuts, and soybeans
– Nuts: almonds, walnuts, pistachios, chestnuts, hazelnuts, and cashews
– Seeds: sunflower, flax, and pumpkin

PATIENT EDUCATION
* Patients started on dapsone should be made aware of potential hemolytic anemia and the signs associated with methemoglobinemia.
* American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumberg, IL 60168-4014; (708) 330-0230
* The University of Chicago Celiac Disease Center, 5841 S. Maryland Ave., Mail Code 4069, Chicago, IL 60637; (773) 702-7593; [www.celiacdisease.net](http://www.celiacdisease.net) or [http://www.cureceliacdisease.org/](http://www.cureceliacdisease.org/)
* Gluten Intolerance Group of North America, 31214-124 Ave. SE, Auburn, WA 98092; (206) 246-6652; fax (206) 246-6531; [https://www.gluten.org/](https://www.gluten.org/)
* The Celiac Disease Foundation, 13251 Ventura Blvd., #1, Studio City, CA 9160; (818) 990-2354; fax (818) 990-2379

PROGNOSIS
* DH is a chronic disease with excellent prognosis, provided strict adherence to a GFD is maintained.
* 10- to 15-year survival rates do not seem to differ from general population.
* Remission in 10–15%
* Skin disease responds readily to dapsone. Occasional new lesions (2 to 3 per week) are to be expected and are not an indication for altering daily dosage.
* Strict adherence to a GFD improves clinical symptoms and decreases dapsone requirement. GFD is the only sustainable method of eliminating cutaneous and GI disease.
* Risk of lymphoma may be decreased in those who maintain a GFD.

COMPLICATIONS
* Majority of complications are associated with GSE.
* Malnutrition, weight loss, nutritional deficiencies (folate, vitamin B₁₂, iron)
* Abdominal pain, dyspepsia
* Osteoporosis, dental abnormalities
* Autoimmune diseases
* Lymphomas

CODES

ICD10

L13.0 Dermatitis herpetiformis

CLINICAL PEARLS

- DH is a chronic, relapsing, intensely pruritic rash that often presents with erosions, excoriations, lichenification, and pigmentedary changes secondary to scratching and healing of old papulovesicular lesions.
- Strong association with GSE
- Diagnosis established with perilesional skin biopsy showing DIF demonstrating granular IgA deposits in the dermal papillae
- Serologic levels of IgA transglutaminase aid in diagnosis and monitoring of deviations from GFD.
- Mainstay of treatment is a GFD with dapsone used primarily for short-term symptom relief.

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- A chronic, relapsing, pruritic eczematous condition affecting characteristic sites
- Early onset cases have coexisting allergen sensitization more often than late onset.
- Clinical phenotypical presentation is highly variable, suggesting multifactorial pathophysiology.
- May have significant effect on quality of life for patient and family—recurrent symptoms affect lifestyle and mental health.

EPIDEMIOLOGY
- 45% of all cases begin in the first 6 months of life with 95% onset prior to age 5 years.
- 50–66% of affected children will have a spontaneous remission before adolescence.
- Also, may have late-onset dermatitis in adults or relapse of childhood condition—primarily hand eczema
- Darker pigmented individuals are affected more often than lighter skinned individuals.
- 60% if one parent is affected; rises to 80% if both parents are affected

Incidence
On the rise over the past 3 decades in industrialized countries.

Prevalence
Approximately 13% of children and 7–10% of adults in the US (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Two main hypothesis: immunologic with unbalanced immune response and/or skin barrier dysfunction
- Alteration in stratum corneum results in transepidermal water loss and defect in barrier function.
- Epidermal adhesion is reduced either as a result of (i) genetic mutation resulting in altered epidermal proteins or (ii) defect in immune regulation causing an altered inflammatory response.
- Interleukin-31 (IL-31) upregulation is thought to be a major factor in pruritus mediated by cytokines and neuropeptides rather than histamine excess.

Genetics
- Recent discovery of association between atopic dermatitis (AD) and mutation in the filaggrin gene (FLG), which codes for a skin barrier protein
- Both epidermal and immune coding likely involved

RISK FACTORS
- “Itch–scratch cycle” (stimulates histamine release)
- Skin infections
- Emotional stress
• Irritating clothes and chemicals
• Excessively hot or cold climate
• Food allergy in children (in some cases). Studies of breastfeeding conveying decreased risk versus increased risk are mixed in conclusion (2)[C].
• Exposure to tobacco smoke
